THE EVOLUTIONARY SPIRIT FOR BETTERMENT IN MEDICAL EDUCATION *

ALEXANDER HUGH FERGUSON, M.D., M.B.
President of the Chicago Medical Society
CHICAGO

The time is opportune to indulge in a few remarks relative to medical education. The evolutionary spirit for betterments pervading the land is significant. The teaching and practice of medicine are being influenced by this same spirit. An opportunity, full of possibilities, now presents itself to this body to manifest this spirit by inaugurating a resistless movement for betterments within our educational ranks. The perturbed condition of medical matters in America and abroad, cries for rectification. Medical education must be standardized, systematized and glorified. Innumerable details must be considered and generalized. The materials are present in abundance, the opportunities are ripe, and everything is in readiness for the master-strokes of our educationalists.

A grave responsibility, in fact, rests on this body. You have before you no easy task, but a mighty labor—a labor in which we proffer you our undivided support and prayers. It is your task to evolve out of chaos a practicable system that will be a credit to yourselves and a lasting monument to the genius and tact of American democracy.

I would specify among the many subjects that would profitably come under your deliberations, these in particular: First. *State Medical Education*; second, *Interstate Medical Relationship*; third, *A National Standard of Medicine*.

I notice by your program that "Standards of Admission to the Medical Schools," "Administration of Entrance Requirements," "The Fifth Year in Medicine," "The Medical Library," "What the Internist Wants the Anatomist and the Physiologist to Teach," and "What the Surgeon Wants the Anatomist and the Physiologist to Teach," *etc.*, are to be presented and discussed by members of this body of specialists in medical education. These presentations and these discussions will be gladly received and thought over, again and again, by the medical profession of this city, state and country.

OVERCROWDING OF THE MEDICAL PROFESSION

One great and lamentable condition stands out very prominently in America, namely, that the medical profession is overcrowded—not by the survival of the fittest, but by the survival of the unfit. This is a serious evil which must be remedied. With a population of about 90,000,000 in the United States, we have at least 140,000 doctors (1 to about 642+) who are legally qualified to practice. In England the proportion of doctors to the population is about 1 to 1,250 and in France 1 to about 2,175. In other nations the proportion is still more favorable to the medical profession. To be concise, we do not need more doctors in America, but we do desire a better brand of doctors. It is my deliberate opinion that this evil, which is due to the large number of irresponsible medical colleges, would be remedied by free medical education.

FREE MEDICAL EDUCATION

The fulfilment in the future of long-cherished ideals in the teaching and practice of medicine is a potent reason for the advocacy of free medical education. Free medical education would ensure a proficient medical profession, which, in turn, would protect the public health and enlighten the masses on medical matters. Thus disease would be forestalled, suffering alleviated and deaths prevented. From a financial standpoint, alone, free medical education would prove a boon to the state, for, since every premature death is a loss to the state of from $1,000 to $2,000 by the lowest computation, every life saved through the agency of the medical profession is a corresponding gain. The number of preventable diseases is many, and the number of deaths due to ignorance is simply appalling.

Free medical education, moreover, would play an important rôle in abolishing certain undesirable private medical schools. The teaching of medicine is too sacred a thing to be trusted at all in the hands of these petty medical colleges. In this connection we would do well to follow the example of Germany, which has demonstrated to the world that it has the best systems of teaching and maintaining scientific medicine.

Allow me to conjure up before you the ideal educational tree as I would fain see it in this state in the near future. Behold, it is a stately tree, with its roots firmly implanted in the common schools, from which it receives its nourishment; its sturdy trunk embodying the high schools, from which it receives its stamina; and its branches outspreading into the various departments of the university, where it attains that maturity which enables it to put forth good fruit in arts, in agriculture, in engineering, in science, in law, and in medicine. Then, with the aid of free medical education, would this stately tree bring forth in medicine the rich and abundant fruits to which our commonwealth is logically entitled.

In our grand educational scheme we must not forget that the life motive of a child naturally begins to germinate at puberty. If all were taught that at this age they should begin to map out their futures and were aided in this by the mature judgment of efficient teachers, according to the symptoms and signs presented by the individual, they would be enabled to decide early on a life career. Especially in medicine is it true that the student should begin on his training early in life.

---

* Address of Welcome to the Association of American Medical Colleges, Chicago, Feb. 27, 1911.

MEDICAL TRAINING AND TEACHING

The teachers in the college of medicine should be well paid for their services. In this regard all the colleges of a university should be treated alike. The courses should be made largely elective. This elective system would create a spirit of emulation between the professors as well as among the students. The medical student should be given an examination every year, written and oral, and should moreover be scrutinized socially, politically, and religiously.

Didactic teaching and the reading of books is no longer the sole source of knowledge. Memorizing Gray's "Anatomy" and other text-books is unprofitable. I remember when the student who was most lauded at college was he who gave his answers verbatim as he had read the information in a text-book or received it from the lectures of his professor. The introduction of the laboratories into universities and colleges completely changed the method of teaching and learning. The spirit of experimentation is developed by this laboratory method of training, and an impulse for thought and study is inspired. The student of to-day sees for himself, handles for himself and thinks for himself. The young doctor in the hospital investigates what he hears. The laboratory man expresses doubt of what is presented by others and sees for himself.

There is nothing, it seems to me, of much more importance in the successful teaching of medicine than the ctual personal contact of professor and student, when he professor may inspire and the pupil be inspired by that subtile quality called personal magnetism. While individual attention by the professor to the student is not always possible, yet much can be accomplished along this line by limiting the size of the class—say to twenty or twenty-five members. This comes back as near as possible to the old doctrine of Locke, Montaigne, Milton, Spenser and others, namely, that the student receives the greatest amount of educational benefit under a tutor.

No matter what method of teaching is employed, however, no student can hope to know it all. Time was not long since when we took an arts course and a medical course at the same time. Professor Eliot, the late president of Harvard University, said: "When I was an undergraduate at Harvard I took almost every course that the college offered. Now I think it would take a bright, active minded student at least one hundred years to go through all the courses the college offers."

THINKERS

"Thinkers rise upon us like new stars, a few in a century." Thinkers are not unlike runners inasmuch as some excel others—those in the lead think farther and faster. Incidentally I might mention here that while some of the medical profession think for themselves according to circumstances, environments and conditions, still many of them, as a result of their bad training, "follow the lead" of some one else. The true philanthropists are thinkers and altruistic specialists. To this class belong Rhodes, Carnegie, Rockefeller and others. What a far[illegible]ng influence the philanthropy and thin[illegible] will have for all time upon the edu-[illegible] Just think of the furore that has [illegible]arnegie Fund for Medical Educa-[illegible]s stirred us to the utmost and has set us to thinking afresh. Great praise must be given to John D. Rockefeller for all that he has done for general education and research in medical sciences through his unbounded spirit for the welfare of mankind. A new era has been created, a new future is before us, and it is the honorable duty of this distinguished and learned body to aid Carnegie and Rockefeller in their great work.

4619 Grand Boulevard.

A SAFE AND RAPID METHOD FOR THE ADMINISTRATION OF ANTITYPHOID VACCINE

JOHN P. FLETCHER, M.D.
First Lieutenant, Medical Corps, U. S. Army
WASHINGTON, D. C.

Since the introduction into the British army of the inoculation of bacterial vaccine as a prophylactic measure against typhoid fever, by Wright and Leishman, medical officers, both at home and abroad, have become thoroughly convinced of the value of the procedure in the military service; so that antityphoid inoculation (or vaccination) can no longer be said to be in the experimental stage. In fact recent orders from the War Department make possible compulsory vaccination of an entire garrison in the presence of an epidemic. So consistently favorable have recent statistics been, that it is safe to say that this method of protection against a dread disease will soon cease to be almost exclusive property of the military organization, but will be accepted and eventually enforced as a safeguard to municipal health.

It is not my purpose to attempt to advance argument in favor of the practice or to explain its rationale or results. A careful perusal of the several recent articles by Major Frederick F. Russell, Medical Corps, U. S. A., would, it is thought, convince the most skeptical of the value of antityphoid vaccination and of its effectiveness. The question which will be considered is, Granted a large number of persons from civil or military life to be vaccinated, how can they best be handled with the least possible loss of time and the greatest safety?

In brief, the method used in our army consists in making three subcutaneous injections, at ten-day intervals, of a killed culture of *B. typhosus*. The vaccine is prepared in the laboratory of the Army Medical School at Washington, D. C., and is sent out in 1 c.c., 5 c.c. and 10 c.c. sealed ampoules, the standard content being 1,000,000,000 dead bacilli per cubic centimeter. The first dose is 0.5 c.c. and the second and third doses 1 c.c. each.

The vaccination of an entire brigade would appear at first sight to be a rather stupendous task, and, as hypodermics are usually given, would indeed be such; but the method about to be described, which is the result of facing just such a proposition, has made possible the administration of over 4,000 doses without a single infected arm, and, with two officers working, at the rate of 5 doses per minute.

The principal factors to be considered, then, since the vaccine is standardized and sterile, are the preparation of the subject's arm (experience having shown that [illegible]ers the middle of the posterolateral aspect of the arm [illegible]on of the most advantageous point), and the manipulati[illegible]d with syringe and needle. Several syringes were tri[illegible] varying results. In general it was clearly demon[illegible]strat[illegible] that any syringe which depended on a rubber or [illegible] washer for a tight connection between needle an[illegible] was sure to give trouble and to be short-lived. The best syringe is one with a plain, ground nipple on the barrel, to fit which the bases of the needles are ground. The needles will then stand repeated boiling and still make a tight joint.

It has been suggested that simple plunging of the needle into boiling water or strong solution of phenol or formaldehyd solution is sufficient sterilization; but it is doubtful if the author of such a suggestion would relish being the next man inoculated with that needle after it had been used on a syphilitic. So, in view of the questionable cases bound to appear, each needle was disconnected from the syringe and boiled, a freshly sterilized needle being used on each case.

Records of each case are kept on cards furnished by the Surgeon-General's office, and for this purpose a sergeant is stationed at a desk just within the door by which the men enter the vaccination room. Coat-racks are provided in the hall. The men enter by organizations in as nearly alphabetical order as possible, each with his left arm bare, exposing the lower two thirds of the arm. The necessary data is given to the sergeant as each man enters the "scrub-up" line. Here at the first table the arm is scrubbed with green soap and warm water, rinsed, and the subject passes on to the second table where a second man washes the previously scrubbed area with a 1 to 1,000 solution of mercuric chlorid; he then advances to a third table where the field is rubbed with 95 per cent. alcohol, after which he comes to the officer who is to vaccinate him. This may seem like needless caution, but a glance at the water after a few arms have been washed would prove ample justification for the first step, while the fact that men coming from stables and police work of various kinds, without any preparation whatever, experience no bad results, would indicate its thoroughness.

When the subject reaches the medical officer, the arm is grasped between the thumb and forefinger of the left hand to steady it and pinch the skin taut, while the needle is plunged downward and slightly forward, nearly parallel with the surface of the arm, into the subcutaneous fat. The injection is given with moderate rapidity and the needle quickly withdrawn. The needle puncture is then touched with a glass rod moistened in pure trikresol and the man leaves by another door. The trikresol dries in a few seconds after which the clothing may be replaced.

The use of trikresol in this manner has been very valuable, not only in cauterizing the needle tract, but the slight burn it leaves marks the site of a previous inoculation and prevents the administration of two doses the same day; for in spite of all directions, some men, knowing they must take three doses, will get back in line for another dose. Thus no difficulty is experienced, even with the short-lived memory of colored troopers; for trikresol leaves a white spot for several weeks, and it is impossible to mistake the number of doses received.

The cleaning-up process is conducted in a line and may be as rapid as desirable; the greatest time being consumed in the filling of the syringe and the maintenance of surgical technic regarding the needles. As was stated before, each needle is boiled and for this purpose a small evaporating dish of water containing a little soda bicarbonate is kept boiling over a gasoline torch. An assistant picks up the needles from the table after they are used and drops them in the water to boil, after which they are removed with a sterile eight-inch Kelly clamp and placed point down in the needle-holder. To secure a fresh needle, with the type of syringe described above, it is necessary for the surgeon only to insert the nipple of the syringe into the base of one of the needles in the holder, give it a slight twist and pull it out. It is well, after thus obtaining the needle, to set it firmly on the syringe by grasping the base (which is winged for the purpose) between the fingers and giving an additional twist. In this manner the inside of the base of the needle, its point and shaft and the outside of the nipple of the syringe can in no way become infected. The syringes are of course boiled to start with.

The needle-holder is steam-sterilized in a towel or thoroughly flamed and placed on a sterile towel. Its capacity is such that two surgeons may have sterile needles available at all times and still allow at least one minute for boiling after use. It consists of a sheet of heavily tinned iron so bent that it forms the bottom and sides of a box 10 inches long, 1½ inches wide and 2 inches deep. In the bottom are punched twelve holes about 3/16 inch in diameter, the burr directed inward. It is placed bottom up on the towel and thus furnishes twelve receptacles for needles large enough so that the point may be easily inserted, but too small to pass the base. The burr being directly downward makes the holes sloping enough on the edges so that needles do not catch.

The needle-holder, as before stated, is sterilized and the needles as they are boiled are removed from the water with the boiled clamp and dropped point down in the holes; the bases, projecting above the surface, are readily accessible without the necessity of handling. Sixteen needles will run two surgeons constantly; eight can be in the holder while four are boiling and four waiting to be boiled.

The vaccine ampoules are kept in a 1 to 500 mercuric chlorid solution, removed and dried as needed, and, after shaking, scratched with a file and broken at the neck; the sterile needle is then inserted into the ampoule and the syringe filled. A little practice is necessary to hit the opening in the ampoule every time with a needle, and several needles will be soiled till this practice is acquired; but the use of the vaccine from the original container eliminates one source of infection, while the small opening minimizes dust contamination, which is a factor where so many persons are constantly moving.

By means of the above equipment, two medical officers, assisted by four men, and one non-commissioned officer in charge of records, have been able to maintain an average of between four and five doses to the minute for an hour or more, and while it may seem elaborate and require considerable help, it is in reality a time-saver for both the subjects and the medical staff. At all events it has made the vaccination of from 150 to 300 men (a not unusual daily occurrence) a mere incident instead of a rather formidable task.

In view of the marked interest taken in antityphoid vaccination by civilians in the neighborhood of Fort D. A. Russell, it is safe to prophesy that the time is not far off when civil practitioners will be confronted with the problem of wholesale vaccination against typhoid in schools, etc.

It is hoped that the procedure may not fall into disrepute on account of infections due to the sacrifice of good technic for speed, and that the preceding paragraphs, in which the methods described apparently combines both technic and speed, may contain some useful suggestions.

I wish to acknowledge my indebtedness to Major George A. Skinner, Medical Corps, U. S. A., and to Captain Percy L. Jones, Medical Corps, U. S. A., for invaluable assistance in the working out of this system and the preparation of this article.

THE PREVENTION OF INDUSTRIAL PHOSPHORUS POISONING *

ROBERT H. IVY, M.D.
Assistant Surgeon, Out-Patient Department, University Hospital; Assistant Oral Surgeon, Philadelphia General Hospital
PHILADELPHIA

This paper is based on supervision, extending over two and a half years, of the hygiene of employees in a large match factory, and observation before and during that time of several cases of necrosis of the jaws from various sources.

The subject may at first sight appear to be of interest only to manufacturers and those interested in labor conditions, but it has been recently so much before the general public in newspapers and magazines, and concerns an article of such universal use, that it is deserving of some attention by medical men.

The pathology of phosphorus necrosis of the jaws is not fully understood, but that this is a very common effect of chronic phosphorus poisoning is well known. Whether the result is an expression of the general toxemia sometimes present in these cases, the poison being derived from the blood after absorption into the system, or whether it gains direct entrance through local lesions in the mouth, is still unsettled. The evidence tends to show that both factors may be present in a few cases, though my observation is that the disease (necrosis) as a general rule may be purely local in origin, and that the poison gains entrance through local points of lowered resistance in the mouth, such as decay of the teeth involving the root canals, pyorrhea alveolaris, etc.

It is well established that the white or yellow phosphorus alone is poisonous, and for that reason legislation has been passed in many European countries, including Great Britain, forbidding its use in the manufacture of matches. In these countries the non-poisonous, red, amorphous phosphorus, and the sesquisulphid of phosphorus are used. The red phosphorus is employed in the manufacture of safety matches, which will strike practically only on the box, while matches made from the sesquisulphid strike anywhere. Neither of these forms of match is as satisfactory to the general American public as the common yellow phosphorus parlor match at present on the market.

Federal and state legislation is now being proposed against the manufacture of yellow phosphorus matches in this country, much stress being laid on the danger to employees in factories making them; and it is undoubtedly true that conditions in some factories justify these measures. Mr. John B. Andrews, Secretary of the American Association for Labor Legislation, recently conducted an investigation of match factories in the United States, and reported his results to the Department of Commerce and Labor. The conclusions he reached were on the whole unfavorable to the continuance of the use of white or yellow phosphorus in the manufacture of matches. Newspapers and medical journals in editorials have taken up the cry and unanimously condemn the yellow phosphorus match, without knowing all the facts, and without fully realizing the economic and other conditions involved. Safety and sesquisulphid matches, under the present tariff and labor conditions, cannot be produced in this country in competition with foreign manufacturers, and if this legislation is passed without modification, the match companies of the United States, representing a capitalization of $20,000,000, employing about 5,000 persons, and putting forth an annual product amounting to about $15,000,000, will be driven out of business. The match manufacturers also point out that other trades, such as those involving the use of lead, are more dangerous to employees than the manufacture of matches. These arguments, however, do not justify the use of poisonous phosphorus when there is a non-poisonous substitute, unless the risk to workers can be eliminated. Can this be done? I believe that, barring absolute carelessness on the part of employees, comparable to playing with dynamite on the part of a miner, yellow phosphorus can be used in the manufacture of matches practically without danger.

SAFETY MEASURES

The following is a brief account of the precautions that have been taken during the past two and a half years by one company. Afterward we shall see the results attained.

The company has on its pay-roll about 120 persons—men, women, boys and girls. There are at the present time forty-four women and girls, the rest being men and boys. There are three main departments: (1) the machine room, where the match sticks are cut and dipped by machinery, employing thirty-five men and boys; (2) the filling room, where the matches are packed into the boxes, chiefly by hand, employing forty-forty women and girls, and twenty-two boys; (3) the general department, which includes the chemical room, the saw and planing mill, the printing and box-making rooms, and the lumber-yard.

General Precautions.—The factory is roomy, and is provided with thorough ventilation, whereby there is a complete change of air every four minutes, and the phosphorus fumes are drawn out by air pumps placed directly over the working places. Lunch rooms, apart from the working rooms, are provided, and employees are obliged to wash their hands before eating. They are instructed about care and cleanliness of the mouth and teeth, and warned against eating or chewing tobacco while at work. An antiseptic mouth-wash is supplied free to all employees. Recently a new match has been introduced, which requires only about one-fifth the amount of phosphorus used in the ordinary match, and machinery will be installed shortly that will greatly reduce the personal handling of the matches.

Special Regulations.—No person is permitted to start work in the factory without a certificate from a local dentist, or until he has been passed on by the special examiner at his monthly visit. A visit is made to the factory by this examiner once a month, at which time the mouths and teeth of all workers are carefully examined, and in addition a survey is made of their general condition as to anemia, hypertrophied tonsils, throat and lung trouble, etc. The results of the examinations are carefully noted on cards. Employees with diseased teeth are required at once to visit a dentist, enforced absence from the factory until the work is completed being left to the judgment of the examiner according to the severity of the lesions found, ranging from simple dental caries to alveolar abscess. It is a general rule not to permit those under treatment for any lesion more serious than simple caries to remain at work. At the next visit the treatment that has been carried out is carefully recorded on the cards. All candidates for employment are obliged to have their mouths and teeth put in order before they are accepted. The aim is to select robust individuals as workers, with sound teeth if possible, and to avoid those with devitalized teeth and those wearing fixed artificial appliances such as crowns and bridges. It is not practicable to make this an absolute rule, and if the individual wearing crowns or bridges be otherwise healthy he is admitted, provided his mouth is kept in good condition. All applicants with diseased tooth-roots beyond repair, are sent to have these extracted, and the wounds caused in their removal must have completely healed before permission is given to work. Persons suffering from simple dental caries are permitted to work during the time they are under the care of the dentist, but those who have devitalized teeth or cavities involving the pulp-chamber must wait until the dental work is completed.

---

* Read in the Philadelphia County Medical Society, Feb. 22, 1911.

Monthly inspection, with special attention to the teeth and jaws, keeps the health of the employees right up to the mark, and any development of disease is checked in time. From observation of patients who had worked in the factory for years before the regular examinations were introduced, it is found that the disease may lie dormant for months without any external evidence of its existence, and many of the cases of necrosis arise without pain. The slightest sign of development of an alveolar abscess is sufficient reason for prohibiting the employee from further work until the trouble has subsided. Cases of necrosis due to causes other than phosphorus may of course arise in match workers, and the trouble be attributed to phosphorus. In one case the Wassermann reaction testified to the syphilitic origin of the disease.

RESULTS AND STATISTICS

During the past two and a half years (July, 1908, to December, 1910), 177 persons have been observed for over six months each, divided into departments as follows:

Filling room	97
Machine room	52
General	28
Total	177

Eighty-one of these have worked in the factory for more than two and a half years, that is, before the routine inspections were instituted, as follows:

Filling room	39
Machine room	26
General	16
Total	81

Since the regular monthly examinations have been in force, eight cases of necrosis of the jaws have been found. In one of these the diagnosis of syphilis was confirmed by the Wassermann reaction. Of the other seven, two of the cases began as alveolar abscesses from roots of teeth bearing artificial crowns. Two began from devitalized teeth which had been undergoing treatment for a long period. In another case the man was employed in mixing the chemicals, undoubtedly the most hazardous work in the factory, because it necessitated handling the phosphorus in a concentrated form. Practically every tooth in his mouth had at some time required treatment. The disease rapidly extended and involved the entire lower jaw-bone, resulting finally in the death of the patient. The fatal outcome of this case is to be attributed chiefly to neglect on the part of the patient himself, and his refusal to remain under proper care and to comply with treatment. The man now working in this part of the factory is obliged to have his mouth examined weekly. Two other cases in men employed for nine years occurred after extraction of several badly decayed roots, which they had persistently neglected to have removed. Four of the cases occurred in women working in the filling room, where the matches are packed into boxes by hand. None of these cases can be quoted as an argument against the efficiency of the measures at present in force.

SUMMARY OF CASES

1. Chemical room, male	Lower jaw, fatal
2. Filling room, female	Upper jaw, slight
3. Filling room, female	Upper jaw, moderate
4. Filling room, female	Upper jaw, moderate
5. Filling room, female	Lower jaw, severe
6. Machine room, male	Upper jaw, slight
7. Superintendent, male	Lower jaw, severe

Thus there have been seven cases of true phosphorus necrosis manifesting themselves since the routine examinations were begun, all occurring in persons who had worked at the trade several years before that time. Previously the company had been continually troubled with cases of the disease. (It is interesting to note that in these seven cases, the upper jaw was affected more frequently than the lower, which is contrary to the general teaching.) In Cases 6 and 7 the employees had been with the company nine years, and had worked at the trade longer still without any hygienic regulations. In all of the cases reported the individuals had bad teeth: that is, teeth through which the infection could directly reach the jaw-bone. The disease has developed in no one who has since admission to the factory been subjected to a monthly examination of the mouth and teeth. In no case has the disease developed without a previous dental lesion. At the present time the factory is absolutely free from the disease.

CONCLUSION

The foregoing facts all point to a local infection of the jaw-bone by the phosphorus through diseased teeth as the essential factor in necrosis. In view of these results of observations on 177 persons for periods ranging from six months to two and a half years, it is justifiable to conclude that the measures in operation at the present time are effectual in the prevention of necrosis in persons employed in the manufacture of matches from white phosphorus, and that the substitution of other less satisfactory materials is unnecessary.

1623 Walnut Street.

Conditions Favorable for Cesarean Section.—The mother must be healthy and the child living and at full term. The mother should be under observation for a time beforehand in hospital or nursing home. It must be ascertained by careful examination that Cesarean section is the best available mode of delivery. Any previous handling or examination must be conducted under the strictest antiseptic precautions. The patient must be prepared as is usual for an abdominal section. The usual routine is disinfection of the external genitals and vagina, sterilization of the skin with iodin solution; rubber gloves for the surgeon and all assistants; high median abdominal incision; long swabs packed round the uterus; median incision of the uterus and delivery of the child before bringing the uterus out of the abdomen; thorough cleansing of uterine cavity and making sure of patency of cervix for subsequent drainage; interrupted catgut sutures through the uterine wall, covered in with continuous catgut suture of the peritoneal edges of uterine wound; stitching of the abdominal wound as far as possible in the usual layers, with supporting through and through silkworm-gut sutures.—A. W. Russell, in the *Practitioner*.

AN EFFICIENT AND TIME-SAVING METHOD OF TYING THE SQUARE KNOT

H. EDWARD CASTLE, M.D., and H. A. L. RYFKOGEL, M.D.
SAN FRANCISCO

The time consumed in tying sutures and ligatures during many surgical operations is too great in proportion to the time taken to do the rest of the work. The circumstances under which ligatures must be tied often render the work most difficult and unsafe when done in many of the ordinary ways. The very fine ligature material often used, gloved fingers covered with blood and other fluids, deep and small cavities, the short time one has at command, and the great importance of the security of the knot change a very simple task into one of great moment.

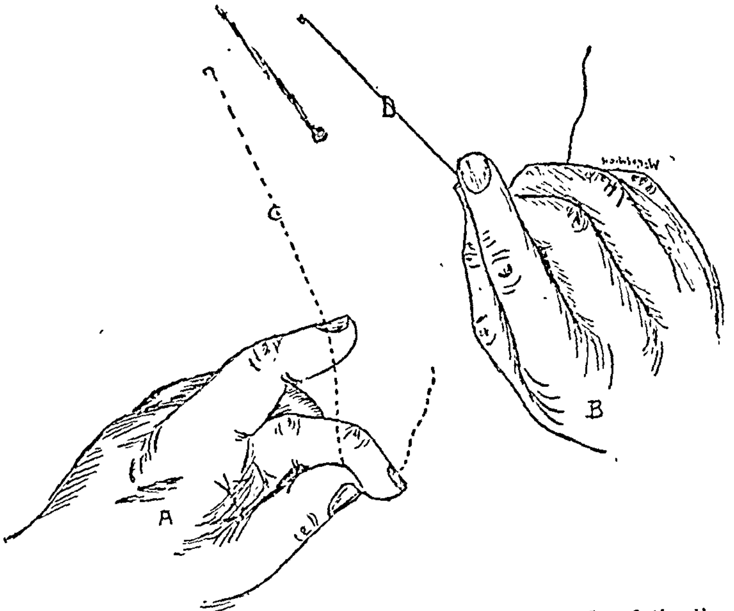

Fig. 1.—Hands (A, left; B, right) grasping the ends of the ligature, ready to make the knot.

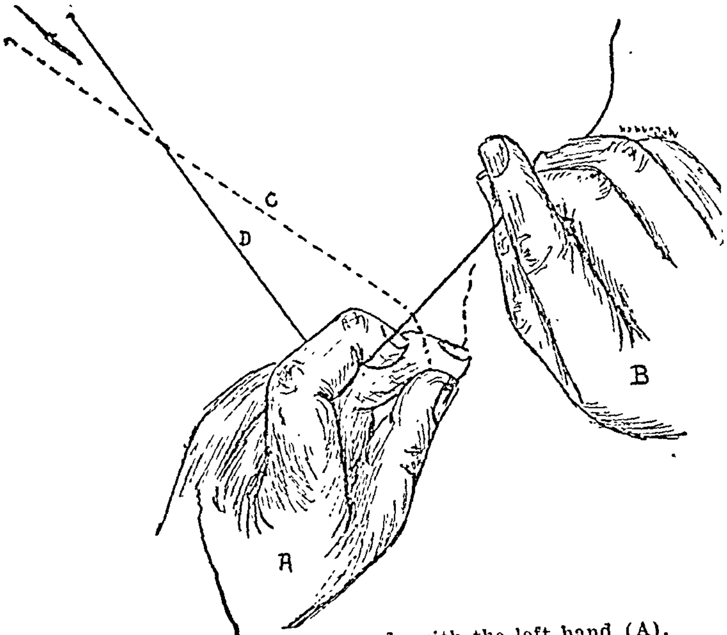

Fig. 2.—First movement, made with the left hand (A).

A knot to be of the greatest value must be one which will not slip or cut the ligature while being tied; it must be simple, requiring few and uncomplicated movements to produce it. It must be made in such a manner that both ends of the ligature are held in the grasp of the fingers while the knot is being tied. It should be tied with one hand. With these important facts in mind we devised the method here described for tying that best of knots, the square or reef knot.

The accompanying drawings were made while the author posed to show each step. To enable the reader to follow each detail, the hands are represented as his own hands, and not as those of some one else whom he is watching.

The left hand (Fig. 1 A) grasps the left end (C) of the ligature between the thumb and the middle finger. The ligature (C) passes over the index finger. The right hand (B) grasps the right end (D) of the ligature. This grip is constant throughout the process of tying the knot. In rapid work the right hand is moved slightly from right to left. The index finger of the left hand is then hooked (Fig. 2) over the end of the ligature (D). The left end of the ligature (C) rolls off of the left index finger. This finger is now further flexed, causing the left end of the ligature (C) to rest on the nail of the same finger. The left index finger is then extended (Fig. 3) and ready to pull C through the loop in D (Fig. 4). The first half of the knot is then tightened (Fig. 5). The middle finger of the left hand will be on the left side of C when the hands are lifted into position over the incision (E).

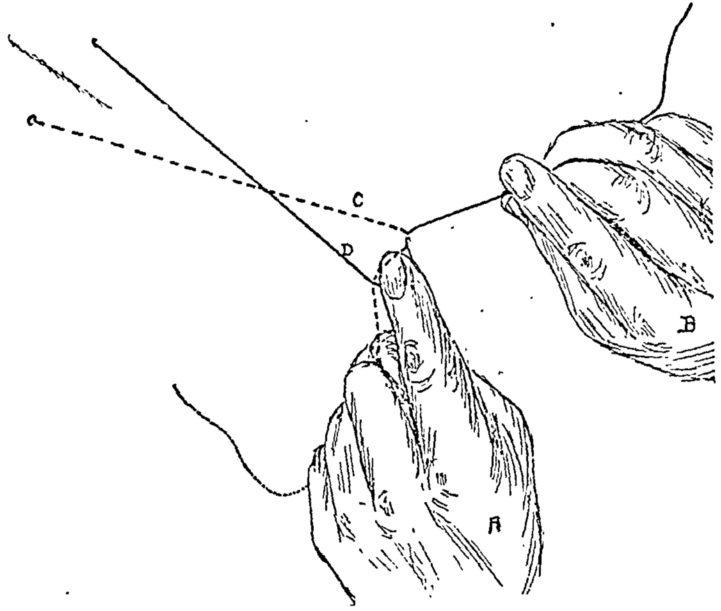

Fig. 3.—The index finger of the left hand (A) making the loop.

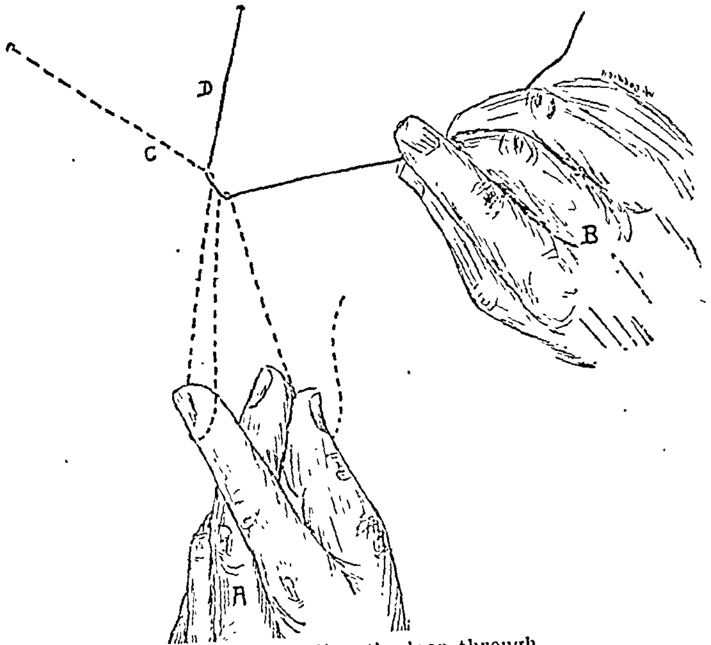

Fig. 4.—Pulling the loop through.

In the second step the thumb and index finger of the left hand hold the left end of the ligature (C), and the left middle finger is hooked under D. By first flexing and then extending this finger C is again hooked through D, and the knot is finished (Figs. 6 and 7).

There is thus produced a square knot which has one turn in either half. This is the best knot for tying ordinary vessels as two turns in one half prevents the ligature from being drawn down to the vessel. The larger the ligature used, and the smaller the vessel to be tied, the greater will be the error by making two turns in the first half of the knot. This knot can be produced equally as well by either hand. If it is desired to have two turns of the ligature in either half of the knot, the same principles can be utilized. All that is necessary is to employ both the left and the right hands simultaneously. The left hand makes the first part of the knot using the index finger while the right hand makes the second part using the middle finger. This will produce the first half of a knot with two turns in it. Now, if the same steps are taken, only in this instance the index finger of the right hand and the middle finger of the left hand are used, the second half of the knot will be made. Each end of the ligature remains in the hand in which it was held in the beginning of the process. It can be produced almost as quickly as the one which has only the single turn in either half.

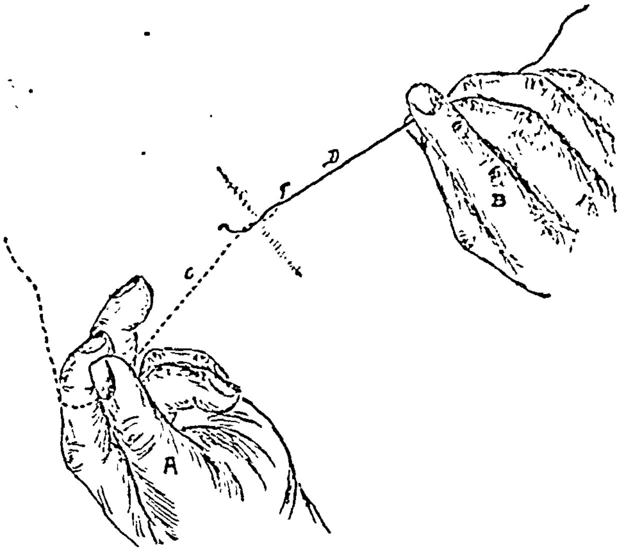

Fig. 5.—First half of knot completed.

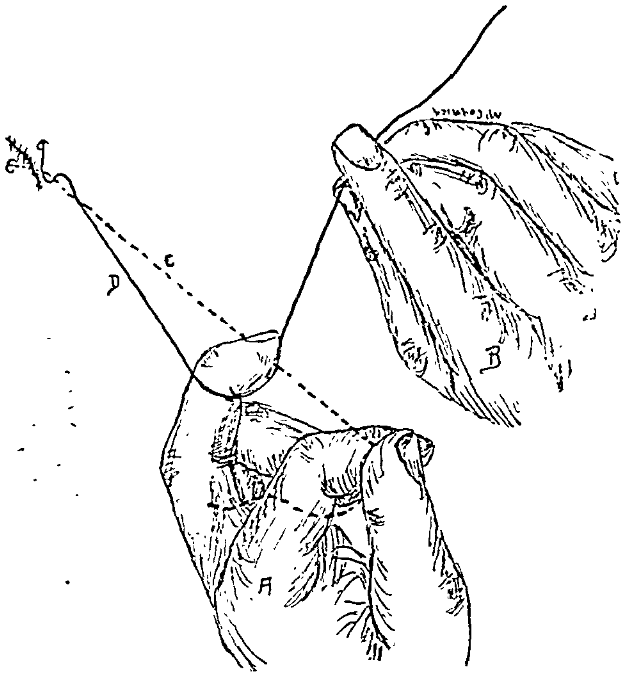

Fig. 6.—The middle finger of the left hand ready to make the loop for the second knot.

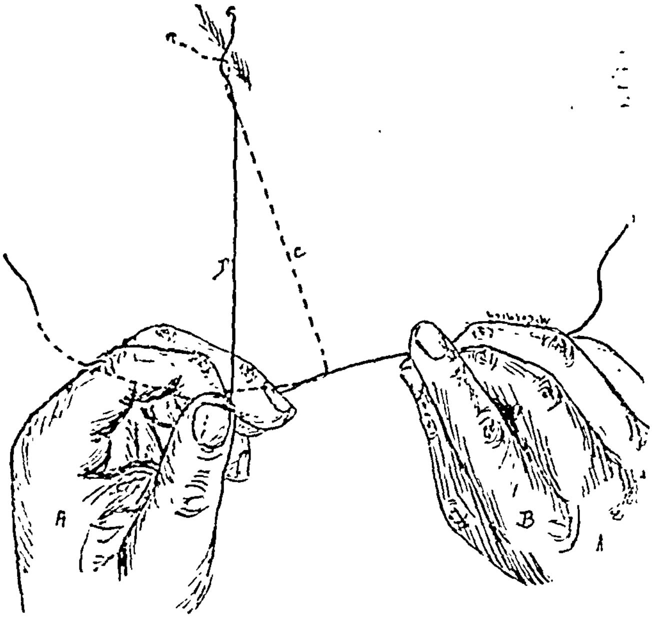

Fig. 7.—The loop made and the knot all but tied.

It should be borne in mind that where there are two turns in the first half of a knot there should also be two in the second, for if there be two in the first part and only one in the second there will be loosening of the first part when the second part is drawn tightly. This is especially true when tying stiff chromic or heavy plain catgut.

1820 Sutter Street.

"INNOCENT" GALL-STONES A MYTH

WILLIAM J. MAYO, M.D.
ROCHESTER, MINN.

Ten years ago we heard a great deal about "innocent gall-stones," which meant that gall-stones existed without symptoms and that their presence was not suspected until post-mortem examination brought them to light. We cannot now escape the conviction that the gall-stones did cause symptoms and that we as diagnosticians, and not the gall-stones, were "innocent."

In the early history of our knowledge concerning gall-stone disease, the diagnosis was not often made until secondary complications and infections had brought about marked local signs and symptoms, or until Nature hung out the yellow flag of jaundice. The mysteries of the disease have, however, been gradually dispelled by operative interference, which has given us pathologic information of the early stages.

It has been stated by good authorities, Naunyn,[1] and others, that gall-stones are present in 10 per cent. of the human race, and this conclusion has apparently been substantiated by the post-mortem material obtained from large hospitals, old ladies' homes, almshouses, etc., but it is quite certain that the illness or disability which placed these people in the hospitals, or disabled them the extent of *becoming a charge* on the community, were in themselves of a nature to bring about gall-stones or to be caused by such disease. It would be idle to estimate, as has been done, that there are sixty million *Germans and that six million*, or 10 per cent. of them, have gall-stone disease. Obviously the premises on which any such computation is based are incorrect.

---

[1] Naunyn: Keen's Surgery, 1910, p. 1006.

Hale White[2] found that, in twenty-five years in Guy's Hospital, there had been 11,333 *post-mortem examinations* of adult subjects, and that just 333, or 3 per cent. of them had had gall-stones. *That this percentage is in* excess of the truth if applied to the population at large seems fairly probable, as again, these adults were not the average "well," but the average "sick." It is more probable that one-half of 1 per cent. would be a fair estimate of the frequency of gall-stones in individuals of all ages, although evidence at hand shows that 5 to 8 per cent. of women and 2 to 4 per cent. of men have gall-stones after the age of 50. From Jan. 1, 1901, to Dec. 31, 1910, a period of ten years, 1,244 women were operated on in St. Mary's Hospital, Rochester, Minnesota (C. H. and W. J. Mayo), for uterine myomata. Of these, ninety-two or 7.1 per cent. had gall-stones.

As regards the presence of gall-stones without symptoms: The symptoms may not be recognized as coming from gall-stones, but if gall-stones are accidentally found during the course of operation for other causes, and the history is retaken in the light of these findings, it will usually be found that symptoms were present but were not differentiated from the symptoms of the disease for which the original operation was undertaken. I have been impressed with this fact on finding undiagnosed gall-stones in operating on women for pelvic trouble. After the recovery of the patient I have nearly always been able to elicit a satisfactory history.

The hypothesis of Lartigau[3] as to the bacterial causation of gall-stones is *probably correct, namely, that the* attenuated infection which seems to be necessary to their formation comes from *infected bile, due to bacteria* which have been carried to the liver through the portal circulation, which were not completely destroyed. That this passage of bacteria through the liver occurs just as certain bacteria pass through the kidney, has been demonstrated. The necessary degree of attenuation of the bacteria has been difficult to reproduce experimentally, and experimental gall-stones therefore have been but rarely produced.

The more common bacterial agents are derived from the colon and allied groups, especially the bacillus of typhoid. Admitting that, in healthy persons, the bile is sterile, in the various intestinal diseases such as typhoid, ileocolitis, etc., an excessive *number of colon* and similar bacteria are carried to the liver through the portal circulation, and experimental work shows that, under such circumstances, these bacteria may be isolated from the bile.

Adami[4] has pointed out that the pigmented *areas in the liver are* derived from the pigments of destroyed bacteria, and in his contribution to the physiology and pathology of the liver, gives many interesting facts in this connection.

It is possible that in some instances an *ascending* infection through the common duct *from the duodenum* to the gall-bladder may cause gall-stones, but we should remember that there is a *constant stream of bile and* pancreatic juice toward the duodenum which interferes mechanically *with* bacterial invasion, and again, as Adami and Cushing[5] point out, the content of the duodenum is relatively free from bacteria. One must also admit the possibility of bacterial invasion of the gall-bladder by way of the hepatic artery or through the lymphatics; but this is equally difficult to prove or disprove.

Gall-stones are originally formed in the gall-bladder, *although later in the disease*, because of obstruction and infection in the common and hepatic ducts, secondary *stones may form in the liver ducts*; but I have never seen hepatic duct stones without evidence that the original *disease had its source in an infection of the gall-bladder or common duct*, and the common duct involvement was almost always secondary to the gall-bladder disease.

The *symptoms of gall-stones* depend on the location *of the stones*, and here the anatomy of the gall-bladder plays an important part. The cystic duct is not continuous with the neck of the gall-bladder, but is elevated *on its inner side*; the neck forms a little pouch which overlaps the duct on its outer surface. It is in this situation, the so-called "pelvis" of the gall-bladder, that *stones are so often impacted*.

It has been a matter of speculation why the gall-*bladder, when filled* with pus and acutely infective material, should not produce more serious constitutional *disturbances. The explanation lies in the fact that the gall-bladder has no* lymphatic glands and very few lymphatic channels; therefore it has not the possibility of ready absorption, and its elastic tissue permits such *speedy distention that* the septic material is not under *sufficient tension* to force the infection into the circulation. *By the time the tension has become great the* lymphatic channels are blocked with inflammatory products and a thick leukocyte sheet protects the gall-*bladder*, as is shown by the great thickening of its walls. When stones in the common duct cause cholangeitis, we *promptly get extreme symptoms, often aguish in character*, due to the relative abundance of lymphatics along the cystic and common ducts and in the fissure of the liver; the temperature often running up to 103 and 105 F. for short periods of time. This sudden elevation of *temperature is usually* accompanied by colic and more or less jaundice, although in the quiescent period about 30 per cent. of cases of stone in the common duct will have little or no jaundice. Movable stones in the cystic duct, with a contracted gall-bladder, will cause intermittent symptoms of the same type as those accompanying common duct stones, but without the jaundice.

Older observers developed the natural history of gall-stone disease from the post-mortem pathology, which was obtained after the ravages of terminal infections and secondary *complications* had grossly changed the conditions which existed during life. The newer or physiologic method of study is based on an investigation of the *early departure* from health, and brings up the question, What is the purpose of the gall-bladder? In times past we have been ready to assert that it was a storehouse for bile, but there is as much bile secreted in twenty-four hours as there is urine; and of what avail would be a storage capacity of one ounce, which is the capacity of the normal gall-bladder? If the conjecture that the gall-bladder is a storehouse for bile were true, *it should have some mechanism* to force the bile out at proper intervals, but no one has ever seen the gall-bladder contract. The muscles in its walls are very scanty, not to be compared to the muscle in the wall of the stomach or the urinary bladder. On the contrary, the gall-bladder is composed largely of elastic tissue and it seems most reasonable to suppose that its function is to take the pressure off the common and hepatic ducts temporarily, and also from the ducts of the pancreas, whenever the necessity arises. Since neither the pancreatic nor the biliary ducts have valves, they cannot protect themselves from abnormal pressure if for any reason the bile and pancreatic juices should not escape readily through the papillæ of the common ducts.

[4] Adami: Cirrhosis, Sajous Annual, 1898.

[5] Cushing: In Robson and Moynihan's Diseases of the Stomach and Their Surgical Treatment, 1904.

The ampulla of Vater is a small chamber in which the biliary and pancreatic secretions mix, and it may be said to resemble the carbureter of a gasoline engine. If the secretions do not escape readily into the duodenum, the back pressure may force the secretion of one organ into the ducts of the other with disastrous consequences.

Opie[5] has shown experimentally, and Halsted[6] has shown clinically, that pure bile injected into the pancreatic ducts will produce acute and usually fatal pancreatitis. In some of our cases of secondary operation at St. Mary's Hospital, in which the gall-bladder had been previously removed, we have observed that dilatation of the stump of the gall-bladder and cystic duct had taken place and that the common duct was almost uniformly dilated; evidently compensatory to the removal of the pressure-reducing gall-bladder.

A second function of the gall-bladder is the production of mucus, shown by the fistulas which follow the destruction of the cystic duct. When the bile passes into the gall-bladder it mixes with the contained mucus. If for any reason the ready escape of the bile into the duodenum is prevented, the mixture of bile and mucus (being subjected to greater pressure in the elastic gall-bladder than the pure bile in the liver ducts) fills the common duct. Therefore, if the contents of the common duct were forced into the pancreatic ducts it would be a mixture of bile and mucus, and not pure bile. Flexner[8] showed that when bile was mixed with mucus, experimentally, it did not produce acute pancreatitis when injected into the pancreatic ducts, but rather the chronic type of pancreatitis, if any harm at all resulted.

In studying the manifestations and complications of gall-stones, I have been impressed with the fact that 86 per cent. of all of the cases of pancreatic disease which we have seen at operation have been complicated with gall-stones. Seven per cent. of all patients with gall-stones in the gall-bladder operated on have had pancreatitis in some form, and in 27 per cent. of cases of stone in the common duct, marked pancreatitis was present. Courvoisier's[9] law holds good, that in 84 per cent. of cases of stone in the common duct the gall-bladder is contracted and practically functionless. We find pancreatic complications four times more frequent in cases of common duct stones than in cases in which the stones are still in the gall-bladder. That the gall-bladder is important as a means of protection, especially to the pancreas, is evident, and is a strong argument against its unnecessary removal.

Gall-stone disease is found to be much more frequent in women than in men. In 4,000 operations which we have performed on the gall-bladder and biliary passages (Feb. 25, 1911, C. H. and W. J. Mayo), 3,075 were in women, and 925 were in men, with an average operative mortality of 2.75 per cent. Eleven per cent. of the total number of deaths occurred in the cancer cases. That there is some cause for the phenomenon which relates to sex, and which cannot be explained by habits, diet, mode of living, etc., seems assured. We (the staff of St. Mary's) have operated on but 3 male patients for gall-stones who were under 20 years of age, while we have operated on 38 females under 20 years of age.

Ninety per cent. of married women who have gall-stones have borne children, and 90 per cent. of these women identify the beginning of the symptoms with some particular pregnancy. The liver of the female should, potentially, be larger than that of a male, since it must functionate for both mother and child. Strange to say, the weight of the female liver is relatively less than that of the male liver, being one fortieth of the body weight, while that of the male is one thirty-sixth of the body weight (Cunningham[10]).

Quiescent gall-stones often become active during pregnancy, and in a number of instances we have been obliged to operate for the relief of rapidly recurring colics, obstruction with infection, or to remove stones which had been forced down into the common duct during the pregnant state. Recovery was always speedy, and in no cases did the operation cause the spontaneous termination of the pregnancy.

The colic of simple gall-stone disease is usually most intense in the epigastrium, passing through to the back, sometimes to the right and occasionally to the left, but seldom radiating below the umbilicus. Spontaneous relief is usually accompanied by a feeling of *movement* of gas or vomiting, and the vomitus more often contains pure bile than does the material vomited in cases which might be mistaken for gall-stone disease. When the pain and tenderness passes into the region of the gall-bladder it is an indication of changes in the wall of the organ, and from this time on the patient does not secure the complete relief between colics which occurred in the earlier stages of the disease, but very often becomes a victim to dyspepsia, indigestion and stomach distress. This is so true that every patient with chronic gastric distress should be questioned intelligently in order to obtain an early history of gall-stone colics, since this information, having apparently no connection with the present symptoms, might easily escape the patient's mind.

Gall-stone disease sometimes causes serious circulatory disturbances. Endocarditis is one of the results, and while it occurs but rarely, it appears to be of a specific type, the development of the heart lesion being coincident with a gall-stone attack; and each exacerbation of the gall-stone disease is accompanied by an increase of the cardiac symptoms. We have operated on some patients with the heart in such condition as to render an operation or even an anesthetic a serious procedure, but the removal of the gall-stones and drainage of the gall-bladder has usually relieved the patient and stopped further cardiac damage, although the heart remained in a crippled condition.

While stones are the most common cause of cholecystitis, in many instances inflammation of the gall-bladder is not accompanied by stones, but nevertheless the patient requires operation for relief. The various forms of cholecystitis have been considered pathologically by MacCarty.[11] One of the fairly common varieties the non-calculous cholecystitis is the so-called "strawberry gall-bladder," in which the mucous membrane has the appearance of a ripe strawberry.

[9] Courvoisier: Pathologie und Chirurgie der Gallenwegen, 1890.
[10] Cunningham: Anatomy, Edition 3, 1909.
[11] MacCarty: Ann. Surg., May, 1910.

Cholecystitis without stones is usually accompanied by habitual tenderness in the region of the gall-bladder. As a rule, colic is not a prominent symptom, and if present is not so severe in character as that accompanying gall-stones. There is often a mild constitutional disturbance, and in some instances, for months at a time, there will be a slight elevation of evening temperature (99 to 100 F.), but without marked loss of flesh; the patient complaining of lassitude and other symptoms of a chronic mild toxemia.

Non-calculous cholecystitis occurs in several forms; the two most frequent are the following: 1. The distended thin-walled gall-bladder contains several ounces of colon-infected bile, often with a foul odor. 2. The wall of the gall-bladder is thickened and white, often adherent and contains a thick, tarry material. In both of these forms the lymph-glands along the common ducts are enlarged. In one of our cases of cholecystitis of long standing (twenty years or more) these enlarged glands had become calcareous, producing sufficient pressure on the common duct to cause chronic jaundice.

Complications were found in more than two-thirds of the patients on whom we operated for gall-stones. Stones were found in the common duct in 492 cases, while serious complications involving the liver, duodenum, transverse colon, etc., were the rule. Carcinoma was found associated with gall-stones in 85 cases (2.25 per cent.). We have removed a number of gall-bladders for carcinoma, and in several instances have excised a piece of the adjacent liver. In cases in which the carcinomatous condition of the gall-bladder was sufficiently advanced to diagnose at the time of operation, the patients did not survive one year, but in a number of cases an early carcinoma was removed accidentally, so to speak, in removing thick-walled functionless gall-bladders, and five of these patients are alive and well at periods of from two to six years after operation.

Gall-stones are foreign bodies. Why delay operating until complications occur? In our experience simple operation for uncomplicated gall-stones has had a mortality of less than 0.5 per cent., and this might be called accidental, since it was due to the condition of the patient, rather than to the operation.

Early operation is relatively safe and the gall-bladder may be saved in a condition for future function. Fatalities can be traced in almost every instance to delay. That temporary palliation can be procured with non-operative measures cannot be denied (Carlsbad, etc.), but the cure of the patient can only be brought about by surgical measures.

In this connection may be noted the wide difference
of opinion between the British and American observers,
on the one hand, who urge early operation, and those
continental observers on the other hand, who advocate
the lay in operation. One of the most prominent of the
bacteriinental surgeons draws conclusions which may be
pathologyzed as follows: 1. Stones in the gall-bladder do
this connecte operation until they have produced marked
It is poss, the wall of the gall-bladder, i. e., formation
infection throu 2. A long incision should always be made
to the gall-bladdor gall-stone disease. 3. The ideal opera-
remember that tof the gall-bladder. 4. Drainage of the
pancreatic juice till usually be necessary. In reply the
y operation would say: 1. In operating

an incision longer than is necessary to introduce the hand for exploration is not often required, and prolonged convalescence and the danger of hernia is avoided. 3. In early operations it is not necessary to remove the gall-bladder, and this valuable organ is saved. 4. Early operation relieves the patient before deep-seated infections occur which necessitate drainage of the liver ducts.

HOOKWORM DISEASE

PREVALENCE, HARMFUL RESULTS AND TREATMENT *

C. F. STROSNIDER, M.D.

GOLDSBORO, N. C.

PREVALENCE OF HOOKWORM DISEASE

Hookworm disease prevails in tropical and semi-tropical regions. Its distribution is now being studied in many parts of the world, and especially in our South; in every southern state a number of physicians are spending their entire time collecting data on its prevalence, and endeavoring as best they may to effect its eradication. Already it is known that the disease exists in Virginia on the Potomac River, in Florida, in Texas and in the intervening states, including North Carolina, South Carolina, Georgia, Alabama, Mississippi, Louisiana, Arkansas and Tennessee.

The following results of investigations which have been made will give some idea of the degree of infection among our people. Chamberlin in 1909 examined a number of southern recruits and found 60 per cent. of them infected. Later Siler in examining 105 recruits found ninety-three infected, which is 88.5 per cent. In North Carolina during the past summer the following examinations have been made with results as indicated (Figures collected by Dr. J. A. Ferrell, director of the North Carolina campaign):

	Examined, No.	Infected, Per Cent.
First regiment North Carolina soldiers	372	36
Second regiment, North Carolina soldiers	366	58
Third regiment North Carolina soldiers	149	32
Coast artillery North Carolina soldiers	218	30
N. C. A. and M. College (colored)	93	16
Presbyterian Orphanage, Barium Springs, N. C.	165	40

Odd Fellows' Orphanage, Goldsboro, N. C.:

	Examined, No.	Infected, No.	Infected, Per Cent.
Total	96	52	54
Girls	51	27	53
Boys	45	25	55
Counties represented	27	21	77

Methodist Orphanage, Raleigh, N. C.:

	Examined, No.	Infected, No.	Infected, Per Cent.
Boys	48	36	75
Girls	83	44	53
Total	131	80	61

Masonic Orphanage (colored), Oxford, N. C.:

	Examined, No.	Infected, No.	Infected, Per Cent.	Ascaris Present
Boys	50	6	12	35
Girls	58	7	12	38
Total	108	13	12	77

The children here, as in the other orphanages, range in age from 6 to 18 years.

Dr. B. W. Page, assistant to the Secretary for Hookworm Disease to North Carolina Board of Health, had 394 children at the Baptist Orphanage examined and found 38 per cent. of them infected. Dr. C. L. Pridgen, is also an assistant in the North Carolina Hookworm Campaign, working in the western section of the state. His examinations of school children showed the following: Fifty-four specimens from Mitchell and Yancey

---

* Read at the medical society meeting of the Fourth District of North Carolina.

counties showed twenty-eight infections with hookworm. and twenty-five with *Ascaris lumbricoides*. Twenty-eight examinations in McDowell County showed twenty-eight infections, or 73 per cent., and in the town of Marion in the same county, 54 per cent. of infection was found in thirty-five examinations.

Serving the North Carolina Hookworm Commission in same capacity as the two physicians last named and working in eastern North Carolina, I found the infection running somewhat higher than in the central and western sections of the state. In the Kinston High School fifty-one were examined; twenty-eight or 55 per cent. of them showed hookworm infection. At Magnolia in Duplin County, seven school children were examined and six were found infected. At Faison, in the same county, twenty-four people were examined whose ages ranged from nine to forty years, and thirteen were found infected. Other schools showed the following:

Wayne County, Eureka,	6 examined,	4 infected, or 66 2/3	per cent.
Wayne County,	21 examined,	19 infected, or 90.5	per cent.
Wayne County,	19 examined,	13 infected, or 68.4	per cent.

Moreover, Dr. K. A. Price, of Hickory, had fifty-six male college students examined and found nine infected. Examinations of school children are now being made in large numbers and the results of these will soon be obtainable. At this time only the figures above given are in my possession. The figures given tend to show that the disease exists in all sections of the state, but that it is more prevalent in the eastern counties. This may be due in part to the fact that the soil is largely sandy and level, factors favoring the propagation of the hookworms; in part to the fact that the negroes, who are regarded as extensive worm-carriers, though they suffer but little from the disease, are more densely settled in the east than in the west, and in part perhaps to the fact that the counties in the tide-water belt have longer and warmer summers than the mountain counties.

Further information on the prevalence of the disease in the state may, it would seem, soon be obtained from our general practitioners. During the first three months of 1910 they sent to the state laboratory only seventy specimens for examination. During the second quarter, which ended June 30, they sent in 486 specimens, and during the three months ending September 30, 1910, they sent in 2,421 specimens. If their interest in the work continues to grow with such rapidity the distribution of the disease may be known to a certainty.

HARMFUL RESULTS

The thorough discussion of the far-reaching harm resulting from hookworm infection would be too lengthy for the present paper. Dr. H. F. Harris, secretary to the Georgia State Board of Health, says: "In no other disease does the victim suffer so long; in no other condition is he for such a period a menace to those about him; in no other malady of such gravity is treatment so rapidly and surely successful." The more immediate results of the disease are of vital importance.

Perhaps the harm produced by the worms will be more easily explained if first a word is given to the characteristics of the worms. They are blood-sucking parasites, varying in length from one-fourth to one-half inch; in numbers they range from less than a hundred to more than four thousand in a single victim of the disease. They inhabit the small intestine and attach themselves by their mouths, which are supplied with powerful muscles, teeth and sucking surfaces, to the mucous membrane. They move from place to place in feeding on the blood they suck from the flesh, each time making a new wound. The loss of blood resulting from their action is of greatest importance. Much blood is drawn directly into the bodies of the worms, but a more important loss perhaps occurs through the minute hemorrhages from the wounds which they make. So great is this latter loss in some instances that the blood in the stool of the victim may be recognized by the naked eye; if it is less, it may be detected by the usual chemical tests. Ordinarily the loss of blood would be somewhat dependent on the number of invading parasites. There are cases, however, in which the number of worms present seems to account only in a remote degree for the symptoms produced. The patient's age, his constitution, his digestive system, and his power to manufacture new blood are points which determine, to some extent, the amount and effect of the loss of blood.

A second harmful result is the poisoned system. The worms are supposed to secrete and inject into the flesh a hemolytic poison, which, moreover, prevents the coagulation of blood in the wounds, from which, therefore, much blood is lost by oozing. Moreover, the excrementitious products from the worms are poisonous, and since the wounds offer points for easy entrance of pathogenic organisms, in many instances the wounds are followed by suppuration, and poisons from such places, when absorbed, increase the general poisoned condition of the patient's system.

In addition to the loss of blood and the poisoning of the system should be mentioned the damage done to the intestine. The numerous bites, together with the poison, give rise to a chronic catarrhal inflammation of the intestine. This impairs digestion and causes tenderness in the epigastric region. To this may be added what is really of sufficient importance for separate consideration. With much denuded and diseased mucosa exposed, disease organisms, particularly tubercle bacilli, and typhoid bacilli, which find entrance into the intestinal canal with food or water, easily pass into the lymphatic or blood-currents and ultimately overwhelm the defenseless victim with the disease they produce.

The secondary changes which result from the hookworms will be best understood by discussing them in connection with the symptoms of the disease. Anemia, with its important effects on all nutritive and metabolic processes, accounts for most of the striking features presented by a hookworm victim, such especially as physical and mental weakness. It also predisposes the person to other diseases and in many instances the ensuing complication is regarded as the primary cause of the death of the person.

For convenience of description I shall classify the disease, according to its harmful results, into four divisions; namely, mild, medium, severe, and very severe.

Mild Cases.—In the mild cases we have, at present, no recognizable symptoms, and they are only diagnosed by the microscope. Though I have found in adults mild digestive disturbances, such as slight reduction of digestive ability, tenderness, pain, and discomfort in the epigastrium, accompanied by nervousness. (This is by no means constant.) Sometimes only a small number of worms are present; again 200 to 300 worms may be present and not produce recognizable symptoms (Dock and Bass).

Medium.—Cases of medium severity have little pallor or have a slightly dirty, yellow tinge of the skin in whites, and a slight pastiness in mulattoes. There is a reduction in the normal amount of perspiration; the appetite is frequently excessive. There may be uneasiness, pain or tenderness in the epigastrium, frequent attacks of meteorism, slight dyspnea on exertion, palpitation of the heart, dizziness, headache, lack of attention to details, and a little stupidity. The muscles are flabby, and weakness and indisposition to labor exists (laziness). The hemoglobin of such persons generally is between 60 per cent. and normal. Joint pains, especially in the sternum, constitute a frequent symptom. The temperature may range from 99 to 101 F.

Severe Cases.—Here all symptoms noted under medium cases are more prominent. The pallor is definite, the mucous membranes are paler than normal, and where the same form a juncture with the skin it often fades away so gradually as to be imperceptible, the skin is quite dry, and sweating is rare. The appetite may be exaggerated or diminished. Nausea is frequent. The tongue is coated and often flabby and enlarged. Tenderness of the epigastrium, with spontaneous pain on gentle pressure at times, is present. (In sixty inspections followed by microscopic examination, this sign has proved positive in every one, being the most constant, most suggestive and most marked of all signs or symptoms.) Breathlessness is easily brought about by the slightest exertion. There is often a hemic murmur of the heart. There may be much pain in the sternum and chest, with a feeling of weakness of the knees and legs. There is much dizziness, especially on sudden changes of position, noise in the ears and frequent headaches. The mental condition is decidedly depressed, and the patient is quite passive to his surroundings, and presents a stupid appearance. The patellar reflex may be either exaggerated or diminished. Patients complain of cold and tingling of the feet, which frequently go to sleep; the muscles are flabby and may be slightly painful; joint pains are so common that a diagnosis of rheumatism is often made. Work is performed with great effort and is deficient in both quality and quantity. In about ten days after ground-itch appears the patient usually develops a sore throat, a slight bronchitis, and a temperature ranging from 99 F. to 102 F. The skin is waxy, tallow or tan color. Edema of the face may be present. The hemoglobin is apt to be between 45 and 70 per cent.

Very Severe Cases.—A case in this stage of the disease may terminate fatally at any time. The skin is tan or tallow-colored. Edema of the feet and ankles alone, or sometimes extreme anasarca may be present. The appetite may be slight or enormous. Nausea and vomiting are frequent. Ascites may be alarming. Diarrhea often alternates with constipation. There is distressing dyspnea on slightest exertion, severe palpitation of the heart, pericordial pain, rapid, weak and compressible pulse, and often dilatation of the heart; marked pulsation of the vessels of the neck; dizziness and tinnitus aurium are extreme; patellar reflex is abolished. In men impotence is an almost invariable symptom, and amenorrhea in women. The intellect is dull and the patient seems confused and stupid. The facial expression is anxious and stupid. There is a tendency to dilatation of the pupil, and blurred vision exists. The urine has a low specific gravity, is abundant in quantity, and usually contains no albumin. The muscles are flabby, sore and painful. Extreme weakness is observed and the patient is incapacitated for labor. There is often irregular fever, with intervals of subnormal temperature.

Acute hookworm disease may occur without previous infection, or an acute attack may supervene on a chronic infection. These acute attacks occur in the spring and summer, and their symptoms vary with the severity of the infection. Should sufficient infection occur, there will be a sore throat, and bronchitis, nausea or vomiting, a chill and diarrhea, epigastric pains or colic, rapid anemia, and elevation of temperature as high as 101 or 102 F. One difference between acute and chronic cases is that the skin is waxy white with severe anemia, whereas in chronic cases, with the same amount of anemia there is a more yellow tinge ("tallow-faced"). Children with acute hookworm disease have not the "pot-belly" present in so many of the chronic, severe cases. In very severe infections, as in Claud A. Smith's experimental case, great swelling occurs on the second and third days. Loose has noticed red lines running up the leg—probably a lymphangitis.

Nervous System.—Insomnia and night terrors are quite common, because of motion of the worms. Somnolence often occurs, and the patient keeps awake with difficulty. Lack of ambition and lassitude are noticeable. After administration of thymol the temperature frequently rises to 102 or 104 F., usually subsiding in twelve hours. I offer the following explanation of this phenomenon: When the thymol comes in contact with the worms they become very active; the thymol causes them to vomit and purge most of their ingested blood (Bass); at the same time they eliminate a large amount of toxin; much blood escapes from their points of attachment. Therefore, if the hookworm toxin acts as a direct poison, and the blood absorption acts as an auto-intoxicant, I feel that a rise in temperature would be accounted for.

QUESTIONS BEARING ON POSSIBLE ADDITIONAL HARMFUL RESULTS

1. May not many cases of neurasthenia and hysteria be attributable to hookworm disease?

2. Could not such perversions, among hookworm patients, as disobedience, profanity, lying, stealing, drinking, forging, and sexual perversions be attributable to hookworm disease, provided recovery followed cure of the hookworms?

3. Is not chlorosis or "green-sickness," in many cases a result of uncinariasis?

4. Is it not probable that a number of cases of defective eyes and ears, and diseased tonsils and adenoids could be attributed to the same cause?

5. Is it not true that many abortions and miscarriages can be attributed to anemia resulting from hookworm disease?

6. Does not observation show that, as Dr. Nicholson of Onslow County says, whereas the average eclampsia with first child in the United States is 1 to 250, in women suffering with hookworm disease the average is 1 to 50.

7. Is it not probable that many women die from shock during labor as a result of hookworm disease?

8. Is it not a fact that, as a result of this disease, many women cannot furnish sufficient milk to nourish their babies?

9. Is it not a fact that hookworm disease is the cause of more amenorrhea, dysmenorrhea, and scanty and irregular menstruations, than any other disease in our South?

10. Is it not a fact that a hookworm patient, pregnant, quite often suffers with a severe dropsy, and often after delivery may run an irregular temperature for some time and fail to react to tonics or quinin?

TREATMENT

External.—Ground-itch in the papular or vesicular stage may be treated with a 5 per cent. salicylic acid suspended in collodion. This usually cuts the attack of ground-itch to one or two days. During the pustular state, the wound should be cleansed and cauterized with silver nitrate and then a dry dressing of 5 per cent. boric acid and zinc oxid ointment applied twice daily.

When great swellings occur hot applications should be used. To allay itching and prevent secondary infection a combination 5 per cent. zinc oxid and salicylic acid ointment applied locally, twice daily, is recommended. It is important to keep the foot bandaged or covered to prevent scratching or rubbing.

Internal.—Treatment should be begun on the fifteenth day from date of the ground-itch and repeated once. The same treatment should be instituted after an attack of ground-itch as if eggs were present in the stools, thus getting rid of the worms before they reach maturity and have done much harm. The stools should be examined at the end of six and twelve weeks from the attack of ground-itch for eggs of any worm that may have escaped previous treatment.

Preliminary.—The first step is to remove the protecting chyme and mucus by a large dose of salts—Rochelle, Epsom or Glauber's—four hours after the last meal. Sodium sulphate dissolves and removes the intestinal mucus best. The drugs used to kill or expel the worms are thymol, betanaphthol and male-fern.

Dose of Thymol.—The dose for children should be in proportion to the size, apparent age, and physical condition. Ashford and King give the following table of doses, to be regulated, in the case of children, rather by size than by actual age.

	Grains.
Under 5 years	7½
5 to 10 years	15
10 to 15 years	30
15 to 20 years	45
20 to 60 years	60
Over 60 years	30 to 45

I have been giving about 2 grains per year up to the age of 30, the same to be administered in two equal doses two hours apart. Unfavorable conditions, such as great weakness, extreme anemia, diarrhea, cardiac depression, pregnancy, and dropsy, require a smaller dose.

Mode of Administration of Thymol.—This should be given in two or three broken doses to prolong its presence in the upper bowel. Because of its tendency to pack together under pressure or in the mucus in the intestine, equal parts of sugar of milk or some other soluble substance should be mixed with it. To prevent its burning of the mouth and throat, it should be given in cachets, wafers, or capsules; it may also be given suspended in either mucilage or syrup of acacia or some simple syrup. The patient should lie on the right side and refrain from drinking much water, to prevent vomiting. After two or three hours another brisk purgative of salts (never castor oil) should be given to prevent its absorption. The patient should remain in bed until the thymol is moved off. Either the bed-pan or the commode should be used in the room to avoid possible fainting.

Diet During Thymol Treatment.—To keep the alimentary canal clean, no food or drink, except water, should be allowed from the time the preparatory purgative is given until the purgative following the thymol has acted well. If the patient is weak or faint, or if the burning in the stomach is excessive, a little warm coffee may be allowed. The diet need not be restricted after several free movements have occurred following the post-thymol purgative, unless there is some special indication. The treatment should be repeated once a week until examination of the stool, washed through a piece of cheese-cloth, shows no worms, or the microscopic examination shows no eggs.

Saturday evening and Sunday is the most convenient time to administer the treatment to working people and school children. The salts purge should be given Saturday evening and thymol begun early Sunday morning. For example, Saturday at 8-9 p. m. sodium sulphate may be given; Sunday at 6 a. m., thymol; Sunday at 8 a. m. thymol again; at 10 a. m., sodium sulphate. Until 4 p. m. the patient should not eat, or drink anything except water, and but little of that.

Caution.—Oils, fats (milk or butter), patent medicines, or beverages containing alcohol should not be allowed during thymol treatment. Thymol may affect the patient in one of three different ways: by intoxication, by irritation of the kidney, and by irritation of the stomach and intestine. The effects of absorbing a large amount of thymol are depression, headache, weakness, dizziness, tinnitus, nausea, unconsciousness, rapid, weak pulse, and sometimes profuse sweating and subnormal temperature (about ½ gr. of thymol is soluble to the ounce of water). The effect of thymol on the gastro-intestinal canal is occasional epigastric pain, nausea and vomiting, and more or less diarrhea. Therefore gastritis, and diarrhea or dysentery are contra-indications. About half a dose should be given to a very weak subject the first time.

Treatment of Toxic Symptoms.—Cardiac stimulants should be given, morphin and atropin, strychnin, digitalin or ergot, subcutaneously, and hot coffe per rectum. Alcoholic stimulation should be avoided. The patient should be kept recumbent. Hot blankets should be applied to the body and a warm water enema used.

301 South Williams Street.

SANITARY CONSIDERATION OF HEALTH RESORTS

HAROLD B. WOOD, M.D., C.S.
JACKSON, MISS.

The recommendation of health resorts is frequently expected of physicians who unconsciously assume the risk, little thinking what effects, both good and bad, the individual town or hotel may have on its guests. Convalescents, travellers and vacationists visit the health and summer resorts unsuspecting of any danger or with the confidence that the conditions are as the physician assumes or expects. The mere mention or naming of a resort by a physician is considered a recommendation and a therapeutic direction to be followed as any other therapeutic order. Opinions of resorts must be formed from personal observation, from description by others, or advertisement. There is an avoidance of the whole truth in many advertisements, yet these misstatements or evasions are accepted without question, and serving as the directing force, may ultimately end disastrously to the guests and finally to the resorts.

Had one physician, referring to a western town as a well-known health resort, known its true condition and the possibility of contracting typhoid fever there, he would have pronounced it anything but a health resort.

Up to the present there has been no proper sewerage in the town. The water-supply is obtained from driven wells located within the city limits. The subsoil is badly polluted with sewage which, unless a change is made, must inevitably dangerously pollute the water-supply, thereby causing an epidemic which may be extensive and serious to the victims, besides ruining the reputation of the resort.

There being such a multitude of resorts in each state, and it being impossible to learn of the conditions in the various localities and resorts, there is needed some method by which the desired information may become available. Physicians should know what constitutes safety in a particular resort, and should give recommendation to the safe ones rather than condemnation to the backward or careless places. In consequence of this recognition of the dangers of certain resorts these places, aided by private or official instruction, will learn the value of sanitary conditions, and appreciate that it is necessary in their competition for existence.

Many resorts are ideal, but it is the occasional hotel or town, conducted blindly, without any medical or sanitary supervision, which becomes a risk amounting to a menace. When a resort installs sanitary conditions and maintains an active regard for the health of its patrons it should be publicly recognized as safe. Sanitary conditions imply much more than plumbing fixtures. If the resort furnishes pure water, pure foods, and has eliminated noxious gases, plants and insects, and becomes in no way a distributing station for environmental or infectious diseases, it deserves the recognition and patronage of physicians. In publishing any list of safe and well-equipped establishments there should be no discrimination against the smaller resorts in favor of the larger, stronger and more wealthy places. The resorts should be judged not alone by their financial outlay or advertisements, but by their activity in maintaining true health-giving conditions.

The resorts which are not safe are in such condition more from ignorance than indifference, and from an inability to understand what constitutes lack of sanitation rather than from a disregard for the safety of others. The proprietors of such places need instruction in what constitutes sanitary requirements, what is purity in water and foods, how infection may be transmitted and how to guard against disease. The information is more welcome when presented in a manner to show the influences each objectionable condition can have on the proprietor's family and guests and on his income and prosperity. If an utter disregard for the safety of the patrons is evinced, it may be necessary to use other than suasive measures. Then official threatenings, legal force or publicity of conditions may be judged by some to be required. Such was the opinion of the New York State Department of Health, which considered itself obliged to publish the names of some sixteen resorts in that state, *warning the public of the many dangerous conditions maintained.*

The revolting conditions in a few resorts may be cited: One hotel discharges sewage into a lake only a short distance from its water-supply intake; another hotel takes its water from a small lake which receives the sewage of hundreds of people; ground directly beneath the hotel guests' windows is covered with the overflow from cesspools; in spite of window screens I found many anopheles in my hotel room every morning; a well supplying drinking-water to a hotel is within thirty feet of a privy, another within ten feet; toilet accommodations are notoriously insufficient and out of repair in some hotels; one hotel disposes of its garbage by emptying it along a roadside; a resort town has its water-supply pipe laid in the same trench with its sewer, the outlet of the sewer being within three feet of the intake of the water-pipe in the same stream. The main sewer of one well-known shore resort discharges on its most frequented bathing beach.

These resorts are the exceptions; but it is these exceptions which constitute the dangers and should be eliminated. Other resorts, on the other hand, are equipped with water-filters and sewage disposal plants of the highest efficiency, and take extreme care to preserve the purity of all surroundings and supplies. One actively prohibits the fertilization of fields within five hundred feet of the stream which is its water-supply, and no water from barnyards or even remote privies can enter the stream.

An attempt to collect sanitary data by mail failed, owing to many not replying, many not appreciating the value of details, and other health officers not being versed in the conditions of resorts in their jurisdiction or not being able to judge of safety. One officer declared there was no opportunity of their supply of river water being polluted, "except from towns above this." Another town obtaining water from the lake into which the sewage is discharged declares there is no danger of pollution.

Owing to the neglect of sanitary conditions and the refusal to listen to warnings there have occurred in isolated hotels outbreaks of typhoid which resulted in numerous deaths, public condemnation, loss of prestige and business failure for the hotels.

The sanitary inspection and control of resorts should be one of the duties of the state board of health. For four years the New York State Department of Health has been carrying on activities among its mountain and shore resorts with good effect. The resorts were mostly found in satisfactory condition, but there were occasional evasions of esthetic and sanitary requirements. Of twenty-six resorts in the Raquette and Saranac water-sheds, inspected in 1908, only seven obtained their water-supply at a distance from the resort grounds and away from any possible source of pollution. Two resorts used lake-water; twelve discharged into lake. The pollution of lakes and bathing beaches constitutes a serious danger. Of twenty-four resorts on Long Island, reinspected in 1908, ten failed to comply with the orders to abate nuisances. As a rule the proprietors are willing to make corrections, but are ignorant of what constitutes dangerous conditions. The welfare of the guests at some localities is admirably protected as at Upper Saranac, Richfield Springs and Sylvan Beach. There are many resorts, from Bar Harbor to Pinehurst and Los Angeles, which have spent much money in obtaining pure water.

In maintaining state sanitary control there should be classed as health resorts all towns usually advertised or considered as resorts, hotels used by summer or winter visitors or vacationists, pleasure and recreation resorts, parks and camps, the so-called watering places, the so-called medicinal spring resorts, bathing or watering places patronized by excursionists, and localities or institutions advertised as sanitariums or sanatoriums. All of these places can strictly be classed as sanitariums or sanatoriums, for to them people go with the hope of acquiring or maintaining health. The Travellers' Protective Association recently recommended the enactment of state laws placing all hotels under state inspection and fixing a standard of sanitary efficiency and safety as the principal requirement for license. The adoption of such legislation seems desirable.

Mineral spring resorts should be placed under licensure. A committee of competent and accepted authorities should be delegated to determine the status of these resorts and the medicinal value of their treatment and vended waters. License should be granted only after frequent sanitary inspections, and after the advertised analyses of waters and all advertisements and resort literature comply with the true virtues of the waters as expressed in the opinion of the medical authorities. Misbranding in the advertisements of these and other resorts and hotels is a menace to health, since people place dependence in the resorts without consulting physicians. The widely circulated assertions that certain mineral springs will cure long lists of diseases places these resorts on the same footing with nostrums and exerts a damaging influence on those baths which possess great value in the treatment of certain specific diseases. The misbranding of resorts becomes a crime. The enforcement of truthfulness in the literature and advertisements of all places and objects on which people place dependence for health and life becomes a state's duty. If a resort commits the double crime of wilfully or knowingly deceiving people by *concealing its dangers*, publicity of conditions and public condemnation of that resort would seem to be just.

In cities it is more practical to keep the infected transmitting agents away from the people; but in small resorts or isolated hotels it is more practical to keep the infected people away from the agents which they may infect; as, in cities to keep the infected mosquitoes away from the people; in resorts to keep the infected person screened from the mosquitoes. The controlling influence must be exerted against the infected carrier which is in lesser numbers and more easily isolated, whether it be man or insect, food or dirt, water-supply or sewage.

Too much reliance should not be placed on crude mortality rates when judging the healthfulness of a locality. Only when statistical tables are calculated to consider age groupings and individual susceptibilities then the figures be considered of much value. The general death-rate of a town may be high from a large infant mortality, yet the place be perfectly healthy for visitors. The mortality rates may be low, owing to native insusceptibility, but the danger to visitors great. In a healthy town the rate may be augmented by diseased persons going there for the benefit they may derive. The influence of hospitals within the city or in adjoining cities and the factor of imported or exported cases should be considered, and receive an allowance in the published rate. Some towns, like one large resort, unrightfully glory in a low rate by transporting their patients to hospitals in other cities, or because their transient visitors develop symptoms only after returning to their homes. Large cities are unjustly obliged to bear the burden of including in their rates many cases which have been contracted through the carelessness or ignorance of other localities. Statistical records which are used for comparison should include only those cases which originate within the town. The summer distribution of a town's population throughout the infected areas of the country is the factor, more than any other one, which is accountable for the great rise in the typhoid mortality in the fall. It has been estimated that 22 per cent. of the typhoid cases in the District of Columbia are imported. Ten per cent. of the cases in Philadelphia are imported, the ratio in the fall (1909) being over half. In 1909 of 2,336 cases of typhoid fever 231 were proved to have been imported, twenty-nine of these cases coming from one summer resort. Twenty-eight of the other cases originated in other resorts.

Eliminating the statistical factors of susceptibility and age grouping, some idea of the existing conditions may be gathered from the typhoid rates in the registration area. The general rate for the area for 1907 was 30.3; for 1908, 25.3 per 100,000 population. Colorado, a resort state, was highest with a rate of 47.7 in 1908 (63.7 in 1907). The fact that Pennsylvania's rate of 50.3 in 1907, was reduced to 23.9 in 1909, shows what can be accomplished through the energy and work of a state department of health. Of the registration cities in 1907, the typhoid list was headed by Escanaba, Mich., a lumber town and summer resort, with a record of 220.2 (126.5 in 1908). The notoriously high rate of Pittsburg (130.8 in 1907) was eclipsed by Jacksonville, Fla., with a rate of 155.1, yet the dangers to health of the latter place are rarely mentioned. The excessive rate of Niagara Falls (126.6 in 1907) may fortunately soon be lowered, for in place of furnishing Buffalo's sewage, purified water may soon be supplied from an effective filtration plant. Philadelphia was long called a typhoid-infected center, yet a comparison with cities which people unsuspectingly visit expecting to regain health, will indicate misplaced conviction.

TYPHOID MORTALITY RATES OF RESORT TOWNS

	1907.	1908.		
Escanaba	220.2	126.5	St. Petersburg	80.7
Jacksonville	155.1	104	Havana	39.3
Niagara Falls	126.6	....	Paris	21.7
Key West	109.8	44.4	Montevideo	18.8
Salt Lake City	93.2	47.4	Brussels	17.2
Savannah	77.3	22.5	Rio Janeiro	15.9
Sacramento	76.7	97.8	Vienna	5.1
Denver	67.1	54.8	Berlin	5
San Antonio	66.9	44	Stockholm (1907)	4
Long Branch	69.9	60.6	London (1907)	2
Saratoga Springs	52.9	....		

San Antonio's rate does not indicate the quality of her water, which comes from clean artesian wells far *outside the city*. The recent epidemic at Montreal disclosed the condition of her water, which is taken from the St. Lawrence below the sewer *outfall*.

The malarial mortality rate of the registration cities gives prominence to some conditions and may surprise some health seekers. In 1907 Savannah headed the list with a rate of 111.6 (122.3 in 1908), followed by Memphis and Jacksonville (78.8 in 1907, 58.3 in 1908). The 1908 rate of Charleston was 44.3, while that of New Orleans was but 19.5. It is unfair to judge the health activities of a locality by a mere comparison of rates or by the apparent rapidity of their decline. The conditions with which health officers must contend are variable and in some places almost insurmountable.

Physicians should not be reticent about giving unasked advice, but when opportunity offers should assist hotel proprietors to improve conditions. When the proprietors use such means as are at their command to improve and to maintain health-giving conditions there will be stamped on their resorts a recognition of safety, with the inevitable result of public appreciation, increased prestige, more publicity and more business. The confidence of the public is the chief asset of a resort. It is the forte of sanitarians not to antagonize or to bankrupt, but to instruct, to assist the resort-keepers to install and to maintain resorts in their highest efficiency, and to teach that healthfulness and sanitary safety mean increase of popularity and prosperity.

TRICHINIASIS IN ITALIANS

FOLLOWING THE EATING OF RAW HAM OR "PROSCIUTTO"

MALCOLM SEYMOUR, M.D.
BOSTON

The Italians give much thought to the preparation of their food, palatability being of prime importance, while care in the selection—especially of animal food—seems to be secondary.

I have seen two cases of trichiniasis among Italians in private practice within the past year; and have collected ten other cases from the records of the Boston City Hospital, admitted within the past five years, six of these ten cases being directly traceable to the ingestion of raw ham. These latter cases were among Italians, and the infection was traced to the same source; that is, smoked ham, or "prosciutto." There was one death among the twelve cases.

This raw ham, or prosciutto, was, up to two or three years ago, imported in fairly large amounts, but the recent advance in the cost of food products has made the importation almost prohibitive. The imported ham, however, may be obtained in about every second delicatessen store in the Italian quarter of Boston, and costs about fifty cents per pound. The home-cured or domestic prosciutto is also obtainable for about thirty-five cents per pound, and is cured by the local delicatessen dealers.

The ham which is offered for sale is cut in very thin slices and is eaten in the entirely raw state between slices of bread. The curing process evidently does not kill the trichinæ.

In the cases which came to my attention, the imported ham was probably eaten, according to the statements of the persons who bought it: but so little reliance can be placed in the testimony of the patient, either through fear of prosecution of their dealer, or through fear of having personally committed some breach of the law, that it has been impossible to determine whether they were due to the domestic or imported ham.

The disease, trichiniasis, is much more common than is supposed, and every writer in considering it calls attention to the fact that it is too frequently overlooked. It is moreover, almost always one of easy diagnosis.

H. U. Williams[1] of Buffalo states that in a series of 505 unselected autopsies in persons having died from causes other than trichiniasis, the organism was found in 5.3 per cent. McCollom[2] reported eight cases and one death in an epidemic which occurred in Boston in 1892. Grawitz[3] states that one-third of the cases of muscular rheumatism showed trichinæ at autopsy. F. H. Drew[3] in 1892 reported an epidemic of fifty cases and four deaths. The nature of this epidemic was not recognized until three deaths had occurred, and although witnessed by three physicians, it was not until the fourth week that the disease was even suspected.

In five cases which I have seen, the symptoms in each were practically identical. The first signs of disturbance were puffiness, and a very slight redness of both upper and lower eyelids, and, in most cases, there was in addition, a slight puffiness of the face surrounding the region of the eyes. Pain quickly appeared in the muscular structures, varying in proportion to the amount of motion made with the muscles. Those most complained of were the masseters, the muscles of the back of the neck, those of deglutition, the diaphragm, and the muscles of the extremities, especially of the calf of the leg and the biceps of the arm.

The digestive disturbance was slight, amounting to some nausea, a sense of distress in the stomach region, sometimes amounting to actual pain, the latter possibly due to involvement of the diaphragm, which is a favorite site for the lodgment of the organism. There was considerable diarrhea in almost every instance. Distinct chills, or chilly sensations, often accompanied the period of muscular invasion. The temperature was moderately elevated, reaching 104 degrees in one case. The pulse followed the temperature and varied from 90 to 100.

One of the greatest aids in the diagnosis is the increase in the number of eosinophils in the blood. This seems to be invariably present in the acute stages. Their numbers vary both during the course of the disease, and with the severity of the infection. At the onset they are usually few in number; in one of the above cases they numbered only 4 per cent. at the beginning, before th muscular pain became severe. As the disease progressed they continued to increase and numbered 55 per cent. o the fifteenth day. One very mild case showed not mor than 10 per cent. at any time.

These eosinophils differ from the normal in the following respects: The granules are fewer in number, less distinct, and do not have as punched-out and clean-cut edges. The acid stain is not taken as brilliantly. It is possible that these morphologic differences are due to the fact that they are young cells.

The course of the disease in the above-mentioned cases was perfectly typical, and lasted from three to six weeks.

It should be borne in mind that although the disease is more commonly found in the hog, trichiniasis in man has arisen from the ingestion of trichinous beef,[4] geese, rabbits, and dogs. In a commission[5] appointed by the German government for the study of trichiniasis, the workers reported that trichinæ were digested by the larvæ of flies, and one or two young rabbits were infected by feeding them the trichinous larvæ.

There is no known drug which will kill the parasite either within the intestines or after it has reached the muscles. The treatment now recommended is an i[illegible] purge, preferably of castor oil or calomel, followed [illegible] Epsom salts in doses of one-half or full teaspoon doses daily. Thymol in 5 grain doses three times daily is given as an intestinal antiseptic. If the muscular pain be severe, opiates may be used.

CASE REPORTS

Case 1.—Tony P., aged 24, Italian, was seen August 28, 1909.

Family and past history were negative.

Present Illness.—The patient ate prosciutto at a friend's house Aug. 21, 1909. Six days later his eyelids began to swell and, on account of his appearance, he was accused by his family of having been drunk the previous night. On account of the pain in his muscles he consulted me the following day.

Examination and Course.—Physical examination showed both upper and lower eyelids distinctly swollen and slightly reddened; the whole face was slightly fuller than normal. He complained of pain in both masseter muscles, in those of the back of the neck, on swallowing, in the region of the diaphragm, in the arms, and especially in the calves of the legs. There was considerable prostration and a sense of muscular weakness which became marked during the following two or three days. The temperature was 98.6 F.; respiration 20; and the pulse

[5] Bericht des zur Erforschung der Trichinen-Krankheit von der k.k. Gesellschaft der Aerzte Ernannten Comités, Wien, 1867.

80. The urine was negative. An examination of the blood showed hemoglobin 100 per cent.: white cells 12,000; red cells 6,500,000; and an eosinophilia of 6 per cent.

September 1, 1909. The patient complained of general muscular pain and muscular weakness. Temperature 103.5 F.; pulse 100; respiration 24; physical examination as before, save that in the bases of both lungs there were a few coarse râles.

Without my knowledge or consent the patient was seen by another physician the day before who had made the diagnosis of laryngitis and muscular rheumatism, and had painted his throat with some form of iodin, and had prescribed salicylates.

An examination of the blood showed hemoglobin 100 per cent.; red cells 6,496,000; white cells 22,000; eosinophils 29 per cent.

Under cocain a small piece of muscle was taken from the gastrocnemius, which showed, under the microscope, many trichinæ in active movement. The temperature and pulse remained elevated for about ten days; then, gradually falling, became normal on the sixteenth day. The symptoms subsided with the temperature. Further recovery was uneventful. Although careful and prolonged search for worms was made in the stools at different periods in the disease, none was found.

A friend of this patient, who had also eaten of the ham, was soon taken with symptoms similar to the above, and was confined to his bed for eight weeks. According to the statement of my patient, the nature of the sickness of this friend was not well understood.

Case 2.—M. D. V., aged 23, Italian, was seen Dec. 6, 1909. Family and past history negative.

Present Illness.—The patient has been in the habit of eating raw ham. Six days ago he noticed a swelling of the eyelids and face, and complained of pain and swelling in the arms and legs, and an occasional chilly sensation.

Examination and Course.—Physical examination showed face and eyelids puffy, with tenderness especially of the muscles of the calves of the legs, thighs, and forearms. There was slight general edema. The white cells were 16,000; eosinophils 17.3 per cent.

December 10, 1909.—Condition of patient had remained about the same; temperature was still elevated; complained of much pain in moving the extremities. The white cells were 9,500; eosinophils 13 per cent.

December 16, 1909, the patient complained of great loss of strength. An urticaria had appeared on the trunk and extremities, accompanied by severe itching.

December 17, 1909. White cells 19,000; eosinophils 39 per cent; slight improvement in general condition.

December 23, 1909. White cells 12,400; eosinophils 33 per cent. The patient was well enough to be up and about.

January 3, 1910. White cells 11,000; eosinophils 23 per cent. The patient desired to go home, and although advised to remain at the hospital, he refused, and was discharged Jan. 5, 1910.

In the prevention of trichiniasis, little can be done under local boards of health, or by inspection under federal control, on account of the great cost and other difficulties, legal, financial and practical. The federal law now states that "meat food products imported into the United States shall be accompanied by a certificate of official inspection of a character to satisfy the Secretary of Agriculture that they are not dangerous to the health. The certificate shall set forth the official position of the inspector, and the character of the inspection, etc. . . . The official inspector who signs the certificate shall have his authority viséed before the United States consul" [at the point of exportation].

That the present laws in regard to inspection are of little value is shown by the foregoing cases.

CONCLUSIONS

1. Trichiniasis is more common than is generally supposed, being erroneously diagnosed as typhoid, muscular rheumatism, influenza, laryngitis, neuritis, nephritis, and many other diseases.

2. The diagnosis is not difficult, if in every case of generalized muscular pain a differential count of the leukocytes is made, and, if possible, a bit of muscle excised for examination.

3. More rigid examination should be made at the ports of entry, of foreign meat products, especially those of pork.

4. The eating of all raw animal foods—sausages, ham, smoked beef, and the like—should be condemned. Much can be accomplished by the physician who comes in contact with the Italians, in pointing out the dangers of eating underdone or raw pork foods.

405 Marlborough Street.

TREATMENT OF THE PARALYSIS FOLLOWING ACUTE POLIOMYELITIS

JOHN McWILLIAMS BERRY, M.D.
Orthopedic Surgeon, Albany Hospital
ALBANY, N. Y.

The anatomic relation between the motor nerve-cells of the anterior horn and the muscles of the body is very complex. In this connection Lovett and Lucas[1] have pointed out that the motor cells are arranged in spindle-shaped bundles or groups, extending frequently through several segments of the spinal cord. Whether each motor nerve-cell group represents an anatomic set of muscles, or a functional grouping, has not been determined, but it is known that one group, or center, will sometimes send impulses to two or more muscles; and, on the other hand, one muscle may receive motor impulses from more than one nerve-cell group. The bearing of these facts on the lesions produced in the cord by poliomyelitis and on the treatment of the paralysis following acute poliomyelitis is most important.

Recent investigation has shown that the virus of acute poliomyelitis causes a profuse inflammation within the spinal cord, the most pronounced result of which is an injury or destruction of the motor cells of the anterior horn. This injury or destruction of the nerve-cells causes an interference with the motor function of the cord, and manifests itself in the paralysis of individual muscles or groups of muscles.

Within certain areas of the spinal cord the anterior horn cells which control individual muscles or groups of muscles may be totally destroyed, and the result would be a total paralysis of the individual muscles or groups of muscles so controlled. In other areas of the cord only certain of the motor cells controlling muscles may be destroyed, and in this case the result would be a partial paralysis of the muscles. In still other areas there may be no actual destruction of motor cells or other structures in the cord, but the presence of inflammation and inflammatory products may cause a temporary interference with the function of the cord, which would show itself as a temporary paralysis in the muscles controlled by such areas.

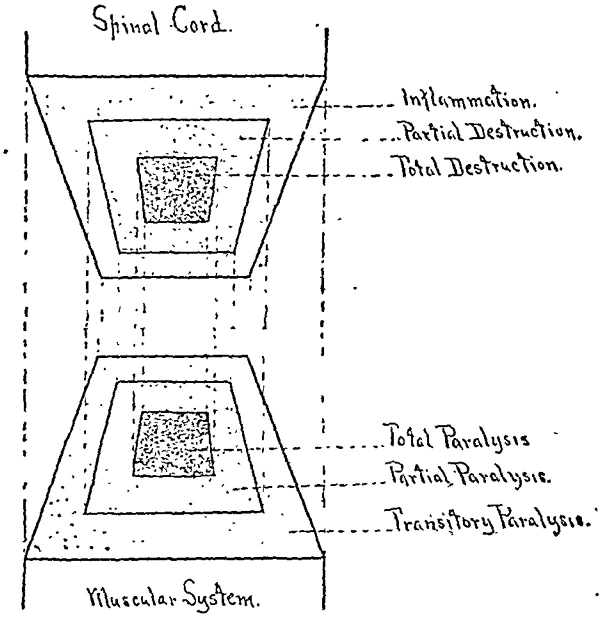
The pathologic changes induced by the profuse myelitis within the cord, and their effects when projected on the muscular system of the body, may be figured schematically as is shown in the drawing.

There are various methods in use in the treatment of the paralysis following acute poliomyelitis. The most important of these are the electrical treatment, the brace treatment, operative treatment, and treatment by massage and muscle-training.

---

[1] Lovett, R. W., and Lucas, W. P.: Infantile Paralysis: a Study of 635 Cases from the Children's Hospital, Boston, with Especial Reference to Treatment, The Journal A. M. A., Nov. 14, 1908, p. 1677.

The electrical treatment is probably in more general use than any other form of treatment and the best authorities seem to believe that the galvanic current is of much more value than the faradic. The chief value of the electrical treatment lies in the preservation of the nutrition in the paralyzed muscles until such time as voluntary control returns. It is best employed, therefore, only in the earlier stages of the paralysis while improvement is taking place. After the paralysis becomes stationary, electrical treatment is of little, if any, use. The great mistake, frequently made in electrical treatment, is to expect too much from it. Too often it is the sole method of treatment resorted to, and many cases can be found in which the treatment has been left in the hands of parents or friends of the patient, who simply rub the poles of a cheap faradic battery over the paralyzed limbs a few minutes each day.



Schematic representation showing in the upper portion the different degrees of pathologic change in the spinal cord in poliomyelitis, and in the lower portion the corresponding impairment of muscle function.

Whitman says of brace treatment, "The object of a brace is to prevent the deformity due to weakness and to utilize the muscular power that remains, so that the disabled member may carry out its function." Another important object of a brace is to obviate the overstretching of muscles with consequent weakening and paralysis.

The use of a brace is not without its objections, however. Mild degrees of paralysis may do better without a brace, since its pressure may cause atrophy and thus defeat the ends for which it was designed; also, severe grades of paralysis do better without a brace, since its weight and pressure tend to retard improvement. On the other hand, brace treatment is absolutely necessary at times. A boy who had paralysis of both legs recovered partially, but was neglected and allowed to walk before his strength had sufficiently returned. He is now able to make practically all movements with his legs and feet; he can flex and extend the thighs and can also flex and extend the legs and feet; he can walk but suffers from a marked degree of genu recurvatum. Nothing would do this patient so much good as a pair of light braces fastened to the shoes, extending to the thigh, and provided with a lock-joint at the knee, preventing hyperextension.

Braces should always be strong, but as light and simple as possible. Thus, in cases of foot-drop, sometimes all that is necessary is a stiff-ankled shoe, or at most a brace going up one side of the leg as far as the knee. In paralysis of the leg, the brace should not be extended to go around the waist unless absolutely necessary. Motion should always be allowed at joints, if possible.

The operative treatment of the paralysis following acute poliomyelitis consists in the correction of deformities, arthrodesis, tendon-grafting, anastomosis or transfer and nerve anastomosis.

The correction of deformity, when present, is always advisable and sometimes absolutely necessary. Thus, a patient with poliomyelitis affecting the legs, and who has been neglected until contracture has taken place at the knees, must, first of all, have the contracture relieved as a preliminary to standing on his feet and walking.

The operations of tendon-grafting, anastomosis or transfer, are frequently beneficial, and sometimes offer the best method of improving the condition of the patient.

Ankylosing operations are sometimes of use, especially at the ankle.

As regards nerve anastomosis, the operation has not developed the brilliant results that its first use seemed to promise.

The consideration of massage and muscle-training has been left until the last because it has proved to be the most important method of treatment. Massage and muscle-training are two distinct procedures in treatment, but they go well together, the muscle-training supplementing the massage. In the earlier stages of the paralysis following poliomyelitis the only other therapeutic agent which can compare with massage is electricity, and massage possesses practically all the advantages of electrical treatment and none of its disadvantages. Massage seems to have an equal value with electricity in preserving the nutrition of muscles and in stimulating them to growth, and it is much more agreeable to the patient. This latter fact is especially true with young children who are very apt to be frightened by electrical treatment.

In giving massage to poliomyelitic patients, it should always be borne in mind that the affected muscles are weak and sensitive. Strong massage would have a tendency to weaken the muscles still more and to hasten their atrophy; the massage should therefore be very light in quality. In the treatment of the late stages of paralysis, massage is of great value as a preliminary to muscle-training.

Before discussing muscle-training it will be of advantage to recall to mind the pathologic changes in the cord in poliomyelitis. It will be remembered that there may be, first, areas of total destruction; second, areas of partial destruction; and, third, areas affected only by transitory inflammation. In relation to these pathologic changes, the paralysis resulting from total destruction is absolute, and it is obvious that no form of treatment can influence it in any way. On the other hand, the paralysis resulting from transitory inflammation is not permanent and will clear up as the primary inflammation clears up, under almost any or no form of treatment.

It is in the paralysis which results from areas of partial destruction within the cord, where the motor cells controlling individual muscles or groups of muscles are merely injured, or only in part destroyed, that the benefits of proper treatment are best observed, and without doubt, muscle-training is the most valuable therapeutic procedure in these cases.

The aim of muscle-training is twofold. In the first place, through voluntary impulses from the brain the effort is made to improve the function of the injured motor cells, and in cases in which there has been a partial destruction of the cells supplying individual muscles, or groups of muscles, the effort is made to train the remaining cells to do the work of the many destroyed. In the second place, the aim of muscle-training is to build up and strengthen the muscles through voluntary contraction. It is a well-known fact that voluntary contractions are much more efficacious in building up and strengthening a muscle than are contractions caused by electricity, or any other means.

Muscle-training should not be started so early as massage. It should not be started until all acute symptoms have subsided and the muscles have lost their irritability. In many cases it may be well to wait as long as a month or six weeks before beginning the muscle-training. Otherwise, the earlier muscle-training can be started, the better it will be for the ultimate outcome of the case.

The treatment of muscle-training is best given on an ordinary massage table or any other firm support. The patient should be freed from distracting influences and encouraged to devote all his energies to the work. All clothing should be removed from the limbs so as not to hamper their movements. Too much should not be attempted at first. The instructor should start with the movements that the patient can make and gradually try to instruct the patient in new movements. It is not a difficult matter to bring the muscles whose nervous mechanism has been but little damaged into activity again, but with other muscles this may be very difficult. There are cases in which the muscle-sense seems to be lost; the nervous mechanism is present, and the power of muscular contraction is present, but there seems to be a lack of coordination between the two. In such cases the patient, while undergoing passive movement produced by the instructor, tries to make the movement himself. In this way, the association-paths in the central nervous system are educated and developed. As soon as a movement has become established, resisted exercises are of the greatest value in developing strength.

Twenty minutes to half an hour a day, or, in some cases, every other day, is time enough to devote to a case. Great care should be taken not to overtire the weakened muscles; the instructor should not be in such haste to get results as to strain the muscles or joints, but he should aim to get some improvement each day. Progress will of course be slow at times and successful treatment requires care and perseverance on the part of both instructor and patient.

In young children, the exercises of muscle-training should be given in the form of play.[2] In older children, the stimulus of competition with other children in a class is advantageous. An appeal to pride and ambition is of value in older patients. Each case is a study in itself.

There is always a temptation to get patients into braces and walking too early. The use of heavy braces is apt to mean the end of improvement. Before the patient is allowed to walk, creeping exercises are of great value; following these, or along with them, the patient is allowed to kneel, and, last of all, to assume the complete upright positon. In the end, braces of some sort will usually be needed.

In cases in which muscle-training has not been started early, in addition to the regular training of the nervous mechanism and the developing of the muscles, contractions may have to be overcome; muscles that have become paralyzed by over-stretching brought into activity again, and muscles weakened and atrophied by disuse strengthened.

Muscle-training is useful in all cases of paralysis following poliomyelitis, and at any stage of the paralysis after the acute symptoms have subsided. In the cases in which brace treatment or operative treatment is necessary the brace or operative treatment should always be supplemented by muscle-training. Muscle-training should be given with a view to ultimately giving up the brace.

TWO CASES OF CESAREAN SECTION WITH UNUSUAL COMPLICATIONS*

COLLIN FOULKROD, M.D.
PHILADELPHIA

CASE 1.—*History.*—The patient, Mrs. G. B. K., white, was 29 years old. Her mother had had ten children and died in childbirth. Three of these children died, no cause known. Until the patient was 3 or 4 years of age she walked normally. For some reason she then lost the use of her lower limbs and has since used crutches. This condition was attributed to a fall and injury to knee-cap. Other than this she gives no history of disease. She was married in June, 1909. Last menstruation was Dec. 1, 1909.

Examination.—June 13, 1910: Patient is a dwarfed woman, presenting the flaccid useless legs of a child who had gone through an attack of infantile paralysis and regained but slight motion. The abdomen was enlarged to about the size of six months' gestation. The pelvic measurements were as follows: Between the spines, 21 cm.; between the crests, 23 cm.; between the trochanters, 26 cm.; left oblique, 19 cm.; right oblique, 19.5 cm.; external conjugate, 15.5 cm.; and internal conjugate, 7 cm. The type was that of an infantile or undeveloped pelvis, outlet being unusually small.

Progress of Case.—Section at term with removal of the uterus, was advised and accepted. The patient's own physician examined the urine until Aug. 1, 1910, and reported it normal. I saw one specimen in the first week of August and found it free from any pathologic elements. On Aug. 9, 1910, scarcely one week later the patient sent for me to relieve sleeplessness and general edema. The edema of face, hands and feet was very marked. The urine secured a few days later was solid albumin on boiling and contained all kinds of casts. The patient was rushed to the hospital and eliminative treatment started vigorously. The total quantity of urine had been diminished before entering hospital. In spite of treatment it rapidly grew less: August 10, 32 ounces; August 11, 13 ounces. She would be at term Sept. 7, 1910, and it was felt that any delay was especially dangerous and from the nature of the operation before us we wished to avoid eclampsia.

Operation.—Aug. 11, 1910. Cesarean section was done; the baby was a living male child, weighing 4 pounds 6 ounces The uterus was then removed by the plan suggested by Dr. E. P. Davis, which is as follows: A silk ligature is placed on each of the ovarian vessels, then heavy hysterectomy clamps are clamped across the lower uterine segment, the uterus being cut off above. The peritoneum is sewed together and then to the sides of this stump which is left free outside the peritoneal cavity to be dressed. The patient is placed on the operating table before ether is started and ether stopped early. In the present instance the entire operation was finished in twenty-five minutes.

Postoperative History.—After operation the urine remained scant. August 12, 4 ounces; August 13, 11 ounces. On August

---

[2] Illustrations of this have been given in a previous article; Albany Med. Ann., April, 1910.

* Read before Philadelphia Obstetrical Society, Jan. 5, 1911.

13, convulsions supervened, and while not frequent they were severe; the patient had six in all, in two days' time. On August 16, the urine secreted amounted to 56 ounces and from that time the woman improved rapidly. The clamps held firmly; the right broad ligament showed some slight trauma from slipping of the clamp in convulsions. The wound healed by sloughing and granulations; the clamps were removed at end of five days. Before this the temperature remained below 99 F., following there was a slight elevation—100 to 100.4 F. from absorption from stump.

The patient left the maternity hospital at the end of a month, having made a good recovery. Both mother and baby are doing well.

Case 2.—*History.*—The patient, Mrs. R., white, twice married, was 41 years old. Her mother died of cancer of the uterus. The patient had had the usual diseases of childhood. She gives a vague history of an abscess in the pelvis which evacuated through the bowel, during first marriage. She was married ten years to first husband, no pregnancies. To her present husband she had been married about two years, and was pregnant four months. She came under my care for an acute attack of pain in the lower left abdomen; temperature was 100-101 F. The pain was unrelieved by the usual measures and a provisional diagnosis was made of pelvic abscess complicating pregnancy with possible rupture and beginning peritonitis.

Operation.—I opened the abdomen and found that the mass which had been discovered in the pelvis, was a soft fibroid, incarcerated in the pelvis, somewhat twisted and congested: it was intramural in origin with a broad base and was larger than the four-months' pregnant uterus from whose left side in the folds and above the broad ligament it arose. There was no evidence of necrosis of the fibroid. After freeing the tumor from the pelvis and finding that myomectomy was an impossibility I refused to do a hysterectomy and closed the abdomen.

Postoperative History.—The pain and temperature subsided immediately; the woman made a rapid recovery and left the hospital at end of ten days practically well except for a slight ether nephritis. She was allowed to go to term, though suffering some unusual discomfort and at times pain in the left side.

Cesarean Section.—On the advice of her physician and because her mother had died of cancer of the uterus, she requested that both baby and fibroid be removed at one sitting. She was taken to Jefferson Hospital (Maternity) and on Aug. 16, 1910, an abdominal hysterectomy was performed, and a well-formed male child delivered. The operation proved somewhat difficult because of the fibroid in the left broad ligament extending down to the vessels of the left side; apparently there was an old adhesion or cicatrix from a previous left-sided pus tube also.

Postoperative History.—The patient was somewhat shocked but reacted well and presented a normal postoperative chart for one week. Then the temperature rose to 101 F. with severe pain in the left side. This pain was relieved only by evacuating through the vault of the vagina a clot of blood in and posterior to the broad ligament where the fibroid and adhesion had existed.

The patient nursed her baby and made a good recovery. The child was small but not deformed—5 pounds 4 ounces.

This patient reported to me December 3. She is gaining in weight, nursing the baby and has no difficulty in the pelvis, but there are some symptoms of the menopause.

These two cases illustrate well the success attained in some complicated cases by the use of abdominal delivery.

There is no form of delivery so rapid as that represented by the first operation, and given a woman in whom future pregnancies are neither desired nor advised we can often save patients in cases which would otherwise be practically hopeless.

In the second case, the fact is illustrated that large single fibroids or even multiple fibroids are no bar to the development of a viable child.

Therapeutics

PRURITUS: ITCHING

To the clinician, pruritus, or itching, represents one of the most puzzling problems in medicine. There are few subjects in regard to which there are so few things definitely known as this one. The clinical manifestations are connected with the terminations of the sensory nerves in the epidermis. Concerning this point there is practical uniformity of sentiment among all observers. As to what affects these nerve endings, so as to give rise to itching: there is a great diversity of opinion. Many believe that it is associated with hyperemia and inflammation of the skin, this condition sometimes resulting in atrophy of the skin, with a continuance of the itching. There are many reasons for believing that these pathologic conditions are not the efficient cause of the itching in many cases.

For example, a common form of itching is pruritus ani, observed in children, caused by the presence of the *Oxyuris vermicularis*, or pin-worm. When these worms are present there may be at times intense itching without any local lesion, or any local disturbance of the nutrition of the skin, evident on ocular inspection. Presence of the worms on the skin in this region gives rise to the itching, but this must be due to something more than the simple presence of small foreign bodies, for no one has demonstrated that this unpleasant symptom may be caused by the presence in the same situation of small pieces of fine thread, or other similar bodies which do not possess active life at the time.

Another common cause of itching, especially in children, is the presence of pediculi, or lice. It seems to be at least open to question whether the itching produced by these parasites is due alone to their presence on the skin in a quiescent state, or even to their active movements on the skin.

Still another instance of intense itching associated with a parasite is that observed in scabies. The startling rapidity with which the symptom of itching subsides under the sulphur treatment of this condition would indicate that the itching is due to something besides the presence of the foreign body, for presumably the application of the sulphur destroys the itch mite, leaving its body in the skin, but as soon as its life is destroyed the itching ceases.

One of the most common forms of itching is that due to the bite of the mosquito. This is certainly out of all proportion to the local congestion and inflammation, and undoubtedly is due to the action of some poison injected by the animal beneath the skin.

Turning now from these obvious external causes of itching and considering the itching caused by jaundice, it will be generally accepted that the itching associated with the common form of jaundice dependent on obstruction to the flow of the bile into the intestine, is due to the irritation of the ends of the sensory nerves by some substance contained in the bile which is absorbed into the blood, or at least by the presence of some product resulting from decomposition of the ordinary constituents of the bile.

Urticaria is another form of skin disturbance associated with intense itching and is frequently due to the ingestion of some unusual article of food. It would seem probable that here the itching is due to some poison carried to the nerve endings in the blood, as is the case in jaundice.

It will be noted that many diseases accompanied by congestion and inflammation of the skin cause itching, but it is a curious fact that the disease, which is constantly accompanied by cutaneous lesions, has as a striking characteristic that its skin lesions are usually unaccompanied by itching. This disease, of course, is syphilis, which we might expect for a double reason would be generally accompanied by itching, but it might be supposed that the poison which unquestionably circulates in the blood and causes the lesions of the skin would give rise to itching, and it would also be supposed that the congestion and inflammatory conditions produced by it would be accompanied by itching, but such is not the fact.

With certain general diseases pruritus is a common symptom, especially diabetes and that common condition associated with abnormal metabolism, known as lithemia, and which is believed by many to be associated with gout. These diseases are all characterized by the presence in the blood of chemical bodies, which ordinarily do not belong there.

It is hardly worth while here to undertake an enumeration of the causes which are commonly assigned for pruritus. They will become apparent incidentally in connection with what will be said in regard to the general treatment of the condition. It has been already stated that the condition is associated with the terminations of the sensory nerves in the epidermis. It is commonly taught by writers that pruritus may be of central origin. It is asserted to be of not infrequent occurrence in hypochondriasis and hysteria. Still another form is described as being of psychic origin, and is seen in insane persons who have hallucinations of the presence of parasites, such as pediculi, on the skin; hallucinations which it is often difficult to remove, and which are sometimes removed only after repeated applications of antipruritic remedies.

In undertaking the treatment of a case of pruritus it is necessary to investigate every organ of the body so as to restore to its normal action, if possible, any organ which may be acting abnormally or which may be under abnormal conditions. First, the condition of the digestive organs must be carefully investigated, and the diet must be carefully regulated. There are two types of people in whom pruritus is seen: one is the stout, robust, plethoric person who is continually over-eating, and the other is the thin, hungry person who is continually starving himself. In the case of the former the diet should be cut down. The protein substances should be greatly reduced, and the starches and sugars should be considerably limited. If it is found that certain articles of food are not completely digested but give rise to fermentation, such articles should be reduced to an amount that can be taken care of by the digestive organs. In the latter class, the thin patients, fatty articles of food should be advised, and an adequate amount of protein should be given to afford adequate nourishment. In both classes, fruits, especially oranges and grapes, will be found exceedingly useful.

If the bowels are constipated, measures should be taken to make them act regularly and abundantly. Small doses of calomel, for a week or two, are sometimes useful for this purpose. For instance, the following prescription may be used:

℞	Cm.		
Hydrargyri chloridi mitis..........	20		gr.iii
Magnesiæ	5	or	gr.lxxv
Sodii bicarbonatis.................	10		ʒiiss

M. et fac chartulas 20.
Sig: A powder three times a day, after meals.

℞	Gm.		
Hydrargyri chloridi mitis..........	10	or	gr.iss
Sacchari	4		ʒi

M. et fac chartulas 20.
Sig.: Take one after each meal.

If this amount of calomel is not sufficient to cause free movements of the bowels, a saline may be given in addition to or in place of it. For instance, 1 or 2 drams of the sulphate of magnesium or of the phosphate of sodium may be given in half a glassful of water in the morning, before breakfast.

Pruritus is frequently associated with deficient elimination, and especially of the kidneys. If the condition of the urine is found to indicate such defective elimination, the internal use of alkalies will generally be found of advantage. In the case of the plethoric individual, with a strongly acid urine of high specific gravity, the following prescription may be used:

℞	Gm. or c.c.		
Potassii citratis	40		ʒx
Aquæ menthæ piperitæ	200	or	fl.℥vi

M. et Sig.: Two teaspoonfuls, in water, three times a day, after meals.

There is no special particular reason for the "A B C" mixture which is used to alkalize the urine either in gonorrhea or any other condition. The acetate, bicarbonate, and citrate of potassium act similarly. It is only a question of taste and the amount used. The citrate of potassium is the most pleasant: the bicarbonate the most disagreeable. The acetate may alkalize the urine in a little smaller dose than does the citrate. The above prescription presents an alkali in a pleasant form and perfectly bland to the stomach. It should be taken with plenty of water. If the above dose, three times a day, does not alkalize the urine (if that is the object desired), it may be administered four times a day.

Although it is admitted that pruritus is associated with the sensory nerves, and it is claimed that in some instances it is due to a disturbance of the central nervous system, no drug acting on the brain, spinal cord or nerve trunks is very effective in pruritus, possibly with a single exception of bromids, which really act by dulling the peripheral endings of the nerves. The treatment of pruritus with bromids is generally inadvisable, as they act by causing nerve debility and later muscle debility and loss of nutrition. Temporarily such treatment is often good treatment.

Generally, in order to stop the itching, it is necessary to apply some drug to the skin which will lessen the sensibility of the ends of the nerves which are in trouble. Several drugs are used for this purpose. The most useful are phenol (carbolic acid), menthol, camphor, chloral, thymol, oil of cade, alcohol and alkalies. The following are a few prescriptions which are suggestive. Various modifications of any one of them may act as satisfactorily.

℞	c.c.		
Phenolis	5		
Liquoris potassæ	5	or	āā fl.ʒiss
Petrolati liquidi....... ...... ad	50		ad fl.℥ii

M. et Sig.: Use externally as directed.
Shake.

Or,

℞	c.c.		
Phenolis	3		fl.ʒi
Glycerini	10	or	fl.ʒiii
Liquor calcis	25		fl.℥i
Aquæ ....ad	100		ad fl.℥iv

M. et Sig.: Sponge over irritated surfaces.
Shake.

SATURDAY, APRIL 8, 1911

RECENT STUDIES OF LEPROSY

From time immemorial leprosy has been held in almost superstitious horror by the laity—thanks probably to the Scriptural attitude toward it; and to physicians even now it presents problems such as are encountered in few, if any, other diseases. In light of recent contributions toward its study, however, many of these problems appear to be in a fair way toward solution. It is almost two years since Clegg[1] first announced the successful prolonged cultivation of the organism of leprosy on artificial media, and Duval[2] since then has devised methods that make this proceding one of comparative simplicity. Clegg's method consisted in first growing the organism along with amebas and symbiotic bacteria; after several transplantations under such conditions, the bacillus became altered sufficiently to permit growth in pure culture. Duval, however, has shown that the essential element necessary for its artificial growth is the presence in the medium of tryptophan and other free amido-acids—factors that were furnished in Clegg's experiments presumably by the action of the bacteria on dead amebas. Like Clegg, Duval found that the bacillus grew more readily after being cultivated artificially for some time. The organism was found by both investigators to be extremely hardy; it resisted a temperature of 70 C. for half an hour, and Duval and Gurd[3] were able to cultivate it from tissues kept in salt solution at room temperature for over eight months. Nor did overgrowth with saprophytic or pyogenic organisms appear to affect its vitality in the least.

Success in animal inoculation has advanced almost equally with the progress in artificial cultivation of the organism. Clegg was able to produce, from inoculation of pure cultures, localized lesions in the guinea-pig closely resembling those in man; and Sugai[4] showed that the Japanese dancing mouse was sufficiently susceptible to undergo systemic infection from local inoculation. Neither of these animals, however, showed a clinical picture like that in man. But Duval[5] has recently, by successive injections of a pure culture of the leprosy bacillus, succeeded in producing in the monkey (*Macacus rhesus*) a type of disease very similar to the human form, and in reobtaining the acid-fast organism from the remote lesions.

Of considerable interest as bearing on the methods of transmission, is the fact that Duval and Gurd were able to cultivate the organism from nasal secretions in two of five cases. They also succeeded in inoculating mice by rubbing cultures of the bacillus into their nares after gentle scarification. Taken in connection with the high resisting power of the organism, these facts would appear to speak strongly in favor of the usually adopted, though much disputed, measure of segregation.

The same investigators have taken up the serum reactions of leprosy. Amboceptor, specific apparently for the lipoid constituents of the organism, they found present in considerable amounts. Agglutinins occurred in small quantities; and the serum of leprous patients was found by them not to differ from that of normal individuals in content of complement. Their results as to specific amboceptor are confirmed by the work of Biehler and Eliasberg,[6] but unlike them, Eliasberg claims to have demonstrated the absence of free complement in the serum of lepers.

It will be seen that as a result of the foregoing work, Koch's postulates have now been fully carried out for leprosy. Considerable light has been thrown on the much argued question of methods of transmission. And with means at our disposal both for obtaining *Bacillus lepræ* in pure culture, and for successfully inoculating experimental animals, further progress should be rapid. Profiting, however, by our many disappointments with tuberculosis—a disease resembling leprosy in so many respects—it will be well to guard ourselves against expecting too much in the way of effective therapy of the disease as a result of recent experimental work.

WHITE PHOSPHORUS

From time to time The Journal has directed attention to the efforts which have been made to obtain Federal legislation prohibiting the use of white phosphorus in the match industry in this country. The stand taken by The Journal is that such legislation is a much-needed step in the direction of public control of the dangerous trades, and that for this reason the medical profession should endorse it. In an article in the present issue, Dr. Robert H. Ivy criticizes this view and presents an argument for the continued use of white phosphorus in the match industry on the ground that "barring absolute carelessness on the part of employees" white phosphorus can be used without danger. He proceeds to give his experience as examining surgeon for one of the match factories, and concludes that the substitution of the safe sesquisulphid for the poisonous white phosphorus is unnecessary, provided proper precautions are observed.

---

[1] Philippine Jour. Sci., 1909, iv, 403.
[2] Jour. Exp. Med., 1910, xii, 649; 1911, xiii, 365.
[3] Arch. Int. Med., 1911, vii, 230.
[4] Lepra, 1909, viii, 203.
[5] Jour. Exp. Med., 1911, [illegible]
[6] Deutsch. med. Wchnschr., 1911, xxxvii, 302-304.

Dr. Ivy says that he requires from the employees of a match factory no unusual precautions, only that they shall not be guilty of a carelessness comparable to a miner's playing with dynamite. This seems to be an exaggerated description of such careless acts as picking the teeth while at work, chewing gum or eating candy while at work, drinking water from a glass standing on the work table, yet all these are recognized as dangerous actions for a match worker.

Dr. Ivy describes conditions in the factory with which he is connected and in which regular monthly dental examinations have been made for a period of two and a half years. No employee who entered the factory during that time has developed necrosis of the jaw. Some of these employees have not been at work more than six months; ninety-six have been there less than two and a half years. Now it is interesting in this connection to consider the length of exposure to phosphorus fumes given in the histories of cases of phosphorus necrosis. The report of John B. Andrews,[1] quoted by Dr. Ivy, gives thirteen histories in which this detail is noted. Ten individuals had worked with phosphorus for periods ranging from three and a half to forty years before they developed necrosis, only three for periods of less than three years. Five more gave the length of time as "several years," which would surely be more than two years. It would, therefore, seem that Dr. Ivy's negative conclusions can hardly be regarded as founded on sufficient data.

It is always difficult for one country to benefit by the experience of another, yet it would really be a great economy of time and effort could we consent to be taught by the past mistakes of our European cousins. We are now in the same position that most of the great European nations occupied ten or fifteen years ago. They wasted many years and permitted much human suffering in their effort to regulate the use of white phosphorus instead of abolishing it, but one by one they were obliged to confess their efforts a failure and to become converts to the prohibition policy. In 1906, an international agreement to prohibit the manufacture, importation or sale of white phosphorus matches was signed by France, Germany, Italy, Switzerland, Holland and Denmark. Great Britain held off, and that country's experience is illuminating for us. In 1898 the British Parliament appointed a committee of three experts to inquire into the question, a chemist, a dentist and a physician. The physician (Thomas Oliver) stated that nothing short of the total prohibition of white phosphorus would make match factories safe, but the dentist gave it as his opinion that proper regulation would meet the danger. Parliament at first accepted the more optimistic view, strengthened the regulations, and provided for examining dentists and doctors; but cases of necrosis continued to be reported, and in 1908 a law was passed prohibiting the use of white phosphorus. In that same year Great Britain signed the international agreement. It would seem then, that regulation of the industry has had a fair trial, and that it is hardly worth while for us to repeat the experiment, for the regulations which proved a failure in Europe were far more stringent that any we should be likely to enact in the United States. It is scarcely probable that our state legislatures would require factories to be built according to government plans, with compulsory medical inspection, notices concerning the dangers of the work which the employer must read aloud to his employees at stated intervals, limitation of the percentage of phosphorus in the paste, etc.

Lest anyone should believe that the situation in the United States differs from that in foreign countries, and that the match industry here is not productive of phosphorus necrosis, we quote from the Bureau of Labor investigation referred to above. There are about 3,500 employees in fifteen of the seventeen match factories in the United States. Of 3,383 whose occupation was specified 65 per cent. are exposed to phosphorus fumes; 95 per cent. of the 1,395 women are so exposed. An intensive study of three factories was made, and eighty-two cases of necrosis were discovered. Andrews describes a factory which is a model in equipment and in care of employees: "Here, if anywhere, careful regulation over many years and favorable conditions should have resulted in the complete disappearance of phosphorus necrosis. Yet forty cases of phosphorus necrosis" (fifteen involving loss of the jaw by operation) "were easily secured."

Were there no way of making matches except through the use of this poison we might resign ourselves to such conditions, but in view of the fact that the industry may be made entirely safe, it seems that as medical men we have no choice but to favor the legislation which is framed to accomplish this result.

PUBLIC HEALTH BULLETINS

The fact is not so well known by physicians as it should be that the national government, through the Public Health and Marine-Hospital Service, is issuing for gratuitous distribution a valuable series of bulletins on matters relating to public health. The series now numbers forty-four, and from the list of those already published it can be seen that at least the more recent ones deal with live and important phases of medicine as it relates to public health. These bulletins have been written by men who have had especial facilities for the ministers of Iola, a resolution was adopted and ordered sent to all the ministerial associations of the state, enlisting their aid in securing the passage of a law to restrict the practice of healing to those who could demonstrate their fitness and qualifications to treat the sick. After asking the cooperation of the ministry "in bringing before the legislature . . . some measure looking toward the more equitable regulation of the practice of the healing art," the resolutions continue: "A large and growing class of 'healers' and 'practitioners' of various names, forms and cults offer their services to the sick and appeal to the public for patronage. They are unlicensed and, therefore, irresponsible so far as regulation by the state is concerned. At the same time they are for the most part ignorant of that scientific knowledge which would enable them to make intelligent diagnoses of disease, to discover contagious diseases and to understand the true limits of their ability, thus causing much needless suffering and numerous untimely deaths. We believe that in the interest of common justice and for the safeguarding of the public health. the laws of our state should be so amended as to require all who assume to treat the sick, by whatever method. to secure a license from the proper state board of examiners after suitable examination as to their qualifications." Probably no men are better able to appreciate the harm done by ignorant "healers" than are the ministers. Their cooperation and support would go far to secure the establishment of a higher standard for entrance into the practice of medicine as well as a stricter and more impartial enforcement of the law for the protection of the public health.

---

[1] A close examination of the histories given by Andrews brings to light several significant facts. Three toothless individuals, with no apparent channel for infection present (the roots had also been removed), developed phosphorus necrosis. A man who had worked developed necrosis. Two individuals are mentioned as being unusually developed it. Two individuals are mentioned as being unusually intelligent and as having taken all possible precautions to protect themselves, yet falling victims to a severe form of the poisoning. One case of fragilitas ossium was discovered. Oliver speaks of having found this condition among the Belgian match workers at Grammont.

NEEDED CHANGES IN ILLINOIS LAW

Senate Bill 235, which, if adopted, will materially strengthen the Illinois medical practice act, has passed the Illinois Senate and is now in the House. The first section of the bill, as we noted two weeks ago, authorizes the State Board of Health to issue a temporary license good for eighteen months, to medical students who have completed a course of instruction and passed the examination of the board, but who have not received diplomas, the object being to permit the board to license hospital interns who are appointed before their diplomas are given them. The second section of the bill authorizes the board to revoke licenses issued under the acts of 1877 and 1887, as well as those issued under the act of 1899. the present act. This provision is made necessary by a decision of the supreme court (*State Board of Health vs. Ross* (1901), 191 Ill., 87; 60 N. E., 811) which held that owing to the phraseology used in the existing law the board did not have authority to revoke licenses issued under previous laws. At present the state board has no power to revoke a license issued between July 12, 1877, and June 30, 1899, no matter what crime or unprofessional or dishonorable act may be committed by the practitioner holding such license. These two provisions are clearly in the interest of better administration of the medical practice act and of better protection to the public; it is to be hoped that this bill will become a law.

MUNYON THE HOPEFUL

"If the Sign of the Cross were to be destroyed the next best sign would be 'The Index-Finger Pointing Heavenward.'" Thus, in a quarter-page advertisement in one of his home papers, speaks Munyon, the genial quack whose uplifted finger, aggressive pompadour and sugar pills have made Philadelphia famous. Genial, did we say? Well, until recently. Of late Fate seems to have been unkind to this erstwhile dispenser of gladness and saccharine innocuity. Unimaginative government chemists are recently reported to have shown that the principal ingredient in Munyon's blood and asthma "cures" was ordinary cane sugar and the "Professor" has been penalized by the government to the tune of six hundred dollars. But, with a supreme disregard for the petty troubles of business, Munyon announces in large advertisements that he is "organizing a Hope Cult, whose mission is to preach Health-ism, Hope-ism and Love-ism." Talk about optimism! And as a clincher, we find heading one of the "Professor's" appeals to the public, this gem:

> "Don't cringe—don't flinch,
> Should fortune pinch
> And all seem lost;
> With might and main,
> Try, Try *again*
> At any cost. —Munyon."

Whether or not the apostle of hope and "homeopathic home remedies," here refers to his business reverses, can only be guessed. That he will "try, try again" to sell his sugar pellets is evidenced by the fact that he has set aside half a million dollars for a new 1911 advertising campaign. "And now abideth faith, hope and charity and the greatest of these"—when backed up with a generous advertising appropriation—is hope!

GOAT'S MILK IN MALTA

Fresh cow's milk is scarce in Malta, and most of the natives use goat's milk. According to U. S. Consul James Oliver Laing, at Valetta, there are about 10,000 milch goats in the islands. These are driven from house to house and milked in the presence of the buyer. Goats are tied at the doors of cafés and when milk is wanted for coffee the goat is milked by the owner. With a little care this method should eliminate much of the contamination of milk under the ordinary methods of handling and distribution. Though a primitive method and applicable only within narrow limits, it would seem to have some advantages. As a large proportion of the goats, however, harbor the germs of Malta fever, the foreign residents refrain from using the milk, and its use is forbidden in the British garrison. Mediterranean fever is intermittent and is one of the most feared diseases in the islands. for, if not fatal, its long duration and the ensuing debility often lead to other maladies Attempts have been made to better conditions on the goat farms, and some progress has been made. Though milk is an excellent food, it seems to have serious disadvantages, even when drawn from original containers.

FREE MEDICAL EDUCATION

Whether or not the remedy for the most serious evils of our present method of recruiting the profession would be relieved by making medical education free, as Dr. Ferguson suggests in this issue, is an open question, and his arguments do not seem convincing. It would be most unfortunate, as President Vincent said in his address,[1] if the expense of obtaining a medical education should prevent those qualified by natural endowments from entering the profession. We doubt, however, whether this would often occur: at all events Vincent's plan of endowed scholarships is more practicable and in other respects better than the attempt to offer opportunities for free medical education without first applying some test of ability. Free medical education would certainly open the way for a still larger number of incompetents. If we are to reach our ideal of every physician being in all respects a thorough scientist and an honorable gentleman, some other method of selection of the material would be more economical and efficient than that of weeding out the applicants in a free-to-all course of medical instruction. It is a question also whether the number of unworthy and undesirable medical colleges would be diminished to such an extent as Dr. Ferguson seems to expect. A sentence in Dr. Ferguson's paper seems to be somewhat open to misunderstanding, to say the least: The scrutiny of the religious, social and political qualifications of candidates, with the popular signification of those adjectives, has a rather unfortunate sound. Of course it was understood by his hearers as it was meant, merely as a statement of the necessity that the physician should be a gentleman of good moral character.

A GERMAN VIEW OF AMERICAN MEDICAL SCHOOLS

In a recent number of the *Wiener klinische Wochenschrift*, a German-American, writing from this country, discusses medical education, especially the low-grade medical schools, and other medical conditions in this country. The *Wochenschrift* says, in an editorial note on this article:

> "All who know anything about conditions in America are full of admiration for the almost model achievements and progress in all lines in that country. It is almost universally conceded that the humanitarian and especially the scientific institutions of America—almost exclusively the creation of private initiative—in the scale in which they are conceived and the perfection of their equipment, cast all that Europe has to offer in this line so much in the shade that the scientists best acquainted with the facts have not hesitated to express their concern that Europe in time will be unable to compete with them, owing to the wise liberality with which scientific research is fostered over there. All this makes it the more interesting to learn that, side by side with conditions almost unsurpassed in their excellence, abuses flourish under the protection of individual liberty—abuses so dire that it seems actually impossible to conceive of their existence, especially in connection with medical education. In the very fact, however, that the Americans themselves have had the courage and the sincerity to lay bare these abuses lies the best evidence of their moral energy and this offers, at the same time, the most certain guarantee of a speedy and radical reform."

While this hearty recognition is encouraging, such a criticism of our educational conditions is and should be mortifying to our national pride. The reasons for the present wide-spread publicity and systematic exaggeration of such abuses as do exist in the profession in America are probably not entirely understood in Germany, yet the *Wochenschrift* is unquestionably right in stating that these abuses "flourish under the protection of individual liberty," and that some of the most flagrant of these abuses are "in connection with medical education." As a people, we have not yet learned that the rights of one man end where the rights of another man begin, and that no individual has a right, even in the sacred name of liberty, to do that which is harmful to the community. The diploma mill and the commercial medical school are unknown in Europe. The ignorant but mercenary physician is justly regarded there as a grave social danger. In these directions we have much to learn from Germany. Only by the establishment and maintenance of high standards of medical education can we hope to retain the respect of other nations and to effect those "speedy and radical reforms" which conditions demand.

Medical News

ILLINOIS

Hospital Bankrupt.—The Evangelical Lutheran Association, Granite City, which owned and managed the hospital in that place, is said to have filed a petition in bankruptcy, March 31.

Personal.—The office of Dr. Joseph Pugue, Edwardsville, was burned, March 27. The building and contents were a total loss.——Fire in Clinton, March 21, destroyed the office of Dr. Joseph C. Myers.

State Sanatorium Bill.—House Bill No. 57 for a state sanatorium for tuberculosis was considered by the judiciary committee of the house of representatives, March 29. Arguments in favor of the bill were made by Representative Shurtleff and by Dr. George W. Webster, president, and Dr. James A. Egan, secretary of the State Board of Health. It is believed that the committee will approve of the bill which carries an appropriation of $500,000.

Scarlet Fever in Chicago Suburbs.—Ravinia, Highland Park, and Evanston have reported recently a number of cases of scarlet fever. In Ravinia, the cause has been traced to a grocery store, in which the postoffice is located, and in which seven children of the proprietor have been ill with scarlet fever, but not quarantined. The contents of the grocery store were confiscated by the State Board of Health and taken to the Skokie Swamp and burned. The store was closed and thorough disinfection of all infected houses was made.

Kill the Optometry Bill.—The optometry bill, House Bill 121, will lie in judiciary committee until action is taken on a similar bill in the senate, No. 140. The State Board of Health requests that the president and secretary of every county society write their senator in Springfield in the name of the society, urging that he oppose Senate Bill 140, and suggests further that the president and secretary urge as many other members as possible to write their senator at Springfield on the same line. The action that the house of representatives will take on the house bill will be predicated entirely by the action that the senate takes on the senate bill. The senate bill is now on order of second reading.

Chicago

Personal.—Dr. and Mrs. Robert H. Babcock and family have returned after two months in California.——Dr. Arthur H. Geiger sailed for Europe, March 31.——Dr. John B. Murphy has returned from a trip to Florida and is ill at his home with typhoid fever.

Health Alliance.—The Citizens' Health Alliance, which was organized in Hull House in November last, has opened permanent headquarters at Room 1202, Ashland Block, and appeals for broader membership. The object of the alliance is to comthe ministers of Iola, a resolution was adopted and ordered sent to all the ministerial associations of the state, enlisting their aid in securing the passage of a law to restrict the practice of healing to those who could demonstrate their fitness and qualifications to treat the sick. After asking the cooperation of the ministry "in bringing before the legislature . . . some measure looking toward the more equitable regulation of the practice of the healing art," the resolutions continue: "A large and growing class of 'healers' and 'practitioners' of various names, forms and cults offer their services to the sick and appeal to the public for patronage. They are unlicensed and, therefore, irresponsible so far as regulation by the state is concerned. At the same time they are for the most part ignorant of that scientific knowledge which would enable them to make intelligent diagnoses of disease, to discover contagious diseases and to understand the true limits of their ability, thus causing much needless suffering and numerous untimely deaths. We believe that in the interest of common justice and for the safeguarding of the public health, the laws of our state should be so amended as to require all who assume to treat the sick, by whatever method, to secure a license from the proper state board of examiners after suitable examination as to their qualifications." Probably no men are better able to appreciate the harm done by ignorant "healers" than are the ministers. Their cooperation and support would go far to secure the establishment of a higher standard for entrance into the practice of medicine as well as a stricter and more impartial enforcement of the law for the protection of the public health.

Mediterranean fever is intermittent and is one of the most feared diseases in the islands, for, if not fatal, its long duration and the ensuing debility often lead to other maladies. Attempts have been made to better conditions on the goat farms, and some progress has been made. Though milk is an excellent food, it seems to have serious disadvantages, even when drawn from original containers.

the coming year. Of this $136.000 is required by the General Hospital, $28.000 for the new contagious disease hospital and $61.000 from the health department proper.

Court Decides Will Valid.—The Supreme Court of Missouri, on March 31, sustained the validity of the will of the late Robert A. Barnes, St. Louis, who bequeathed about $3,000,000 for the erection and endowment of a hospital to be conducted under the rules and regulations of the Methodist Episcopal Church South.

New Officers.—Howard County Medical Association, at its annual meeting in Fayette, elected the following officers: president, Dr. Uriel S. Wright, Fayette; vice-presidents, Drs. Doke J. Gentle, New Franklin, and Wesley R. Hawkins, Glasgow; secretary-treasurer, Dr. Charles W. Watts, Fayette; delegate to the state association, Dr. Joel Y. Hume, Armstrong, and censors, Drs. Charles O. Lewis, Vaughan Q. Bonham and Andrew W. Moore, all of Fayette.

Personal.—Dr. Isaac R. Lane, Mountain Grove, is seriously ill in Alexian Brothers' Hospital, St. Louis.——Dr. Gustav B. Schultz, Cape Girardeau, has been appointed a member of the State Board of Health.——Dr. John C. Edwards, O'Fallon, is reported to be ill at his home.——Dr. Mason C. Alderman, Sedalia, is seriously ill with heart disease.——The trial of Dr. Fred W. Brown, Billings, charged with performing a criminal operation, resulted in complete vindication of the defendant, March 9, when the circuit court judge gave peremptory orders to the jury to bring in a verdict of not guilty.

St. Louis

Red Cross Endowment Fund.—The St. Louis Committee on Endowment of the American Red Cross reports that $53,159.20 have been contributed of the $70,000 apportioned to the city.

Tuberculosis Commission Resigns.—The Municipal Commission on Tuberculosis resigned as a body, March 27, considering that its work had been completed with the establishment of the Robert Koch Hospital.

Fake Physician Fined.—Annibale Inverso is said to have been fined $50 and costs on each of three charges of practicing medicine without a license, March 23. In default of payment of fine he was committed to jail.

Intern Examination.—At the meeting of the City Hospital Board, March 29, Hospital Commissioner Morfit announced that 94 out of the 106 applicants had passed the examination recently conducted for internes in the City Hospital.

Personal.—Dr. Albrecht Collasowitz has returned from abroad. ——Dr. Otto A. Wall, Jr., has succeeded Dr. Albert E. Taussig as editor of the *Weekly Bulletin of the St. Louis Medical Society,* and Dr. Grandison D. Royston has been made associate editor.——Dr. Hugo M. von Starkloff is reported to be seriously ill with appendicitis at St. Anthony's Hospital.——Dr. C. W. Gould, assistant bacteriologist of St. Louis, is reported to be ill with heart disease.

MISSISSIPPI

Personal.—Dr. Vincent Bonelli, Vicksburg, has succeeded Dr. Ewing F. Howard, Vicksburg, resigned as secretary of the Warren-Claiborne County Medical Association.——Dr. B. J. Marshall, Europa, has been elected head counsel of Mississippi Woodmen.——Dr. Sherwood R. Towns, Union Church, has been elected secretary of the Jefferson County Medical Society, vice Dr. John H. Carradine, Fayette, resigned.——A nurse who attempted to shoot Dr. Robert L. Turner, Meridian, two months ago, because of a disagreement is said to have been fined $500.

Society Meetings.—Clarksdale and Six Counties Medical Society held its semi-annual meeting in Clarksdale, March 22. The following officers were elected: president, Dr. Aaron G. Everett, Friar Point; vice-presidents, for Bolivar County, Dr. F. M. Duley; for Coahoma County, Dr. William W. Stuart, Clarkesdale; for Tunica County, Dr. Daniel W. Coker, Tunica; for Quitman County, Dr. Samuel C. Cowan, Sabino; for Tallahatchie, Dr. Sylvanus W. Robinson, Pisgah; and for Sunflower County, Dr. William B. Harrison, Crawford; secretary-treasurer, Dr. Thomas W. Dye, Longwood; censor, Dr. Robert L. Mercer, Shelby; and delegates to the state association, for Bolivar County, Dr. A. M. Wynne, Merigold; alternate, Dr. Thomas D. Allen, Shaw; for Coahoma County, Dr. T. G. Hughes, Clarkesdale; alternate, Dr. E. L. Hooper; for Quitman County, Dr. Frederick M. Brougher, Belen; alternate, Dr. Cyril J. Marshall, Lambert; for Sunflower County, Dr. Richard C. Smith, Potter; alternate, Dr. W. G. Boyd; for Tallahatchie County, Dr. T. F. Clay; alternate, Dr. John A. Harris, Webb; and for Tunica County, Dr. Morris J. Alexander, Tunica; and alternate, Dr. M. L. Minor.——At the annual meeting of the Lauderdale County Medical Society, held in Meridian, Dr. James M. Guthrie was elected president; Dr. George W. Stephens, vice-president; Dr. Samuel H. Hairston, secretary-treasurer; and Dr. William W. Reynolds, delegate to the state association, all of Meridian.

NEBRASKA

Home from Abroad.—Dr. Charles C. Morrison, Omaha, has returned after several months postgraduate work in London. ——Dr. Adolph Sachs, Omaha, has returned after twenty months' study in Berlin and Vienna.

Journal Stockholders Meet.—The stockholders of the *Western Medical Review Company* met in Omaha, March 21, and elected the following directors: Drs. August F. Jonas, Frank E. Coulter, Henry F. Akin, Henry L. Burrell and Harold Gifford, all of Omaha.

State Association Meeting.—The Nebraska State Medical Association will hold its annual meeting in Omaha, May 2-4. Dr. John P. Lord has been made chairman of the committee on clinics; Dr. Louis B. Bushmann, chairman of the committee on management; and Dr. Alfred Schalek, chairman of the committee on entertainment.

NEVADA

Abortionist Sentenced.—Dr. Frederick Hugo Wichman, Reno, charged with causing the death of Mrs. Emma J. Ross by an illegal operation in October last, is said to have been found guilty, March 17, and sentenced to imprisonment for eight years in the Nevada Penitentiary. Motions for new trial and for appeal were argued and denied.

NEW YORK

Fire in State Institution.—Fire on April 2, practically destroyed the Northern New York Institution for Deaf Mutes, Malone, causing a loss of about $135,000. The 100 inmates of the institution marched out of the building without panic or injury just before an explosion occurred.

Medical Club Election.—The Utica Medical Club, at a meeting, March 16, elected Dr. Faust S. DeLong, president; Dr. Raymond L. Baker, vice-president; and Dr. Lewis B. Amsfry, secretary-treasurer. Dr. John Gromann, the president, entertained the club and delivered an address on "Chronic Urethritis."

State Board of Charities.—The board reports that the total number of persons supported by the state during 1910 in the state and reformatory institutions was 11,874. Of this number, 3,001 were discharged and 485 died, leaving on the state's hands 8,388 persons. The total value of property in these institutions is $10,303,899.

Medical Journal to be Offered for Sale.—By the will of the late Dr. William Warren Potter, Buffalo, his estate is left to Miss Margaret Bowden, his secretary and chief assistant for twenty-five years. The principal asset of the estate is the *Buffalo Medical Journal.* The will provides that the *Journal* shall first be offered for sale to the medical department of the University of Buffalo.

Celebrate Semicentenary.—On March 31, Schuyler County Medical Society gave a dinner at the Glen Springs, Watkins, in honor of the fiftieth anniversary of the graduation of two of its members, Drs. Charles D. Clawson, Montour Falls, and Gideon O. Smith, Odessa. After the dinner, Dr. Clawson gave "Reminiscences of a Student of Fifty Years Ago," Dr. Smith read a paper entitled "The Recollections of a Young Practitioner Fifty Years Ago," and the Hon. O. P. Hurd, Watkins, made an address on "The Experiences of a Patient Fifty Years Ago."

The Blackwell Memorial.—At the recent annual meeting of the Woman's Medical Society of New York State, resolutions were passed regarding the recent deaths of Drs. Elizabeth Blackwell, Hastings, England, and Emily Blackwell, New York City, who are recognized as pioneers in the study and practice of medicine, and who by their persevering efforts opened the way for other women to enter that field. The society expressed its deep respect for and appreciation of the character and work of the Drs. Blackwell, its indebtedness to them, and its earnest desire to carry forward the work so nobly begun by them.

New York City

Building for Public Health Service.—The United States Government has awarded the contract for a building to serve as quarters for assistant surgeons of the Public Health and Marine-Hospital Service, Staten Island.

Bequest to Cornell.—The late Dr. Samuel Alexander bequeathed all his surgical instruments and pathologic and anatomic preparations to Cornell University Medical Department.

Personal.—Dr. Reginald Pickett, ambulance physician of St. Vincent's Hospital, Staten Island, was thrown from the ambulance in a collision with an automobile, March 17, and was seriously injured.——Dr. Joseph P. Sheridan, diagnostician of the Queen's Borough branch of the board of health, has resigned, to take effect April 1.

Gifts to Hospitals.—Frederick W. Beinhauer who died recently, provided in his will that on the death of his wife, his real property, less specific bequests, be divided equally between the Presbyterian and German hospitals and St. John's Guild.——Alfred M. Heinsheimer has given $10,000 to the Hospital for Deformities and Joint Diseases as an endowment fund to aid in the equipment and maintenance of the institution.

Fund for Hungarian Hospital.—A new hospital for the benefit of the large Hungarian population of New York City is to be erected on the upper East Side. An option has been secured on several corners between Eightieth and Eighty-Fifth Streets and a large part of the $300,000 for the proposed structure has been subscribed. Plans have been prepared for a nine-story building of steel reinforced by concrete. It is expected that the hospital will be ready for occupancy by the fall of 1912.

Condemnation of Contaminated Food.—Acting under special orders from Health Commissioner Lederle, inspectors of the department of health began, on March 29, active enforcement of Section 46 of the sanitary code, which provides for the shielding of food from dust, dirt, flies and other contamination. The activity of the inspectors was directed especially against street vendors of candy, on whose stands were found large quantities of confectionery exposed for sale in uncovered, unprotected condition.

Gift to Hospital.—Among the many bequests to religious and charitable institutions made in the will of Mrs. Frances Swan Welles is one of $10,000 to the Presbyterian Hospital to provide a permanent fund, half the income from which is to be used to brighten the lives of the nurses in that institution and the other half to brighten the lives of the patients in the general wards. Other bequests were $5,000 to the Bryson Day Nursery and $5,000 to the Belknap Summer Home for Day Nursery Children, Far Rockaway.

Public Drinking Cups Must Go.—Believing the public drinking cup to be a carrier of infectious diseases, the Board of Health has adopted an additional section to the Sanitary Code which will make it unlawful after October 1, 1911, to have what is known as a "common drinking cup" in any public building, institution, factory, theater, school, railroad station or ferry house in the city. The health department is not recommending any special device to take the place of the drinking cup, but experiments by the department have shown that certain stock fixtures can be so arranged as to comply with the requirements of the new ordinance.

Sage Institute Out of City Charities.—The Russell Sage Institute of Pathology, which was founded in 1907 when Mrs. Sage gave $300,000 for pathological research work in connection with the hospitals and charitable institutions on Blackwell's Island, has resolved to terminate the agreement existing with the Public Charities Department and to withdraw its pathologists from the City Hospital and the City Home. Mr. Drummond, Commissioner of Charities, has asserted that the Institute of Pathology used city money without proper supervision on the part of the city; while on the other side the directors of the institute asserted that there was too much politics mixed with the administration of affairs on the island.

NORTH CAROLINA

Hospital News.—A new city hospital will soon be erected in Tarboro.——The new Rutherford Hospital was formally dedicated, March 10. Dr. Joseph Price, Philadelphia, delivered the principal address and held a clinic.——The new infirmary building of the State Normal College for Women, Greensboro, has been completed.

Personal.—The governor has reappointed Dr. Robert H. Stancell, Margarettsville, director of the State Hospital for the Insane, Raleigh, and Dr. William E. Headen, Morehead City, director of the State Hospital for Colored Insane, Goldsboro.——Dr. Isaac H. Faust, Salisbury, has given up the practice of medicine.——Dr. Francis J. Clemenger, Asheville, has been commissioned as captain of the Medical Corps of the National Guard.——Dr. Robert L. Caveness, Coleridge, has been elected president of the Siler City Loan and Trust Company.——Dr. Berte O. Edwards has been elected president of the Merchants and Farmers Bank, Landis.

Work of the Legislature.—In the last session of the legislature the following work of interest to physicians was accomplished: The bill approved by the state medical society and the State Board of Health, requiring a four years' high school course or its equivalent for candidates for medical license, passed the house but was defeated in the senate. This is the third time this measure has been defeated in the legislature.——The appropriation for the work of the new State Board of Health has been increased from $8,000 to $22,000. The board is also to receive about $4,000 as a tax on water companies, and will also save about $4,000 by the agreement of the state to print its *Bulletin* and other publications.——The county sanitary committee has been abolished, and in place thereof there has been created the county board, consisting of the chairman of the board of county commissioners, mayor of the county town, county superintendent of schools, and two physicians elected by them. The board elects the county superintendent of health who may act as quarantine officer if so desired.——State quarantine of small-pox has been abolished, but local quarantine of counties is left optional.——An act was passed creating a board of nine trustees and providing funds for the building and equipment of a state institution for the feeble-minded. Drs. Lewis B. McBrayer, Asheville; Alfred A. Kent, Lenoir; Ira M. Hardy, Washington; and Robert N. Cartwright, Fairfield, have been appointed members of the board.

NORTH DAKOTA

New Hospitals.—The Ward County Hospital controversy has been settled by turning over the hospital to a hospital association organized by the physicians and business men of Minot.——Dr. Arnt G. Anderson has established an eight-room hospital at Hillsboro.

Meeting of State Antituberculosis Association.—At the annual meeting of the North Dakota Antituberculosis Association, held in Bismarck, Dr. James Grassick, Grand Forks, delivered the annual address, giving a brief review of the work of the association for the past year. The association decided to enlarge the state tuberculosis exhibit, and accepted April 30 as Tuberculosis Sunday. It was reported that nearly 80,000 Red Cross seals were sold during the holidays. The following officers were reelected: president, Dr. James Grassick, Grand Forks; vice-presidents, Mrs. H. L. Bolley, Fargo, and Drs. Victor J. LaRose, Bismarck; Victor H. Stickney, Dickinson, and Andrew Carr, Minot; secretary, Dr. Fannie Dunn Quain, Bismarck; and treasurer, Mrs. J. E. Stevens, Grand Forks.

OHIO

New Department of State Board.—Through the efforts of Dr. Frank Warner, Columbus, the department of epidemiology has been established in cooperation with the State Board of Health for the control and prevention of epidemic diseases.

Plans for Sanatorium Accepted.—The final plans for the joint tuberculosis sanatorium to be erected by Columbiana, Stark, Mahoning, Portage and Summit Counties, have been accepted by the trustees. The sanatorium will be located on the Bixler farm near Akron.

Old Physicians Honored.—About eighty physicians of Montgomery Medical Society were present at a banquet in Dayton, given in honor of Drs. James M. Weaver, Dayton, and Samuel Souders, Dean, in celebration of the fiftieth anniversary of their medical practice. Dr. Souders was unable to attend the banquet on account of ill health. Dr. Horace Bonner was toastmaster. Dr. John S. Beck spoke on "Our Guests," and Dr. John C. Reeve, dean of the profession in Dayton, gave "The Greet of a Veteran Comrade."

Personal.—Dr. Harry D. Belt, Kenton, has sailed for Europe.——Dr. Michael A. Bartley has succeeded D. Rush Robinson, resigned, as district physician of the west side of Columbus.——Dr. Myron S. Clark has been reelected president of the board of health of Youngstown.——Dr. Arlington C. Holland, Marion, chief statistician of the state registrar of vital statistics, will, it is said, succeed Dr. Fred L. Watkins, Columbus, in that position.——Dr. W. Dallas Hoyer, health officer of Sandusky, has resigned and has been succeeded by Dr. Hiram D. Peterson.

Health Official Exonerated.—At a meeting of the board of health of Lorain, March 15, a resolution was adopted exonerating Dr. William A. Pitzele of the charges made against him by Dr. William F. Dager of connivance with local midwives. The board concluded that Dr. Pitzele was innocent of any wrongdoing, or breach of professional courtesy, and that he had done nothing deserving censure or in any way reflecting on his professional or personal integrity or honesty. The board also found that the action taken by Dr. Dager in the matter would have been fully justified had the information which he received been founded on facts.

Cincinnati

Personal.—Dr. Sigmund Wolf has been appointed physician to the Municipal Lodging House.——Dr. Clarence Bahlman has succeeded Dr. Franklin H. Lamb, resigned, as chemist and bacteriologist to the Cincinnati Board of Health.——Dr. Robert Maddox has been appointed a member of the orthopedic staff of the City Hospital.

Buildings of Contagious Group Opened.—On March 25 and 26, six new buildings of the contagious group of the Cincinnati Hospital were opened for public inspection. At a meeting of the board of hospital commissioners, last week, the specifications for the entire group of eighteen buildings were approved unanimously. These buildings are in addition to the six of the contagious group just *completed, and will cost in the* neighborhood of $1,850,000. In addition to wards for patients there will be administration building, receiving ward, nurses' dormitory, kitchen and dining room, room for women employees, operating building, power and laundry building, and *stable and garage*. The pathologic building will be five stories in height and will include a morgue, chapel and teaching department.

PENNSYLVANIA

Oppose Antivivisection Bills.—A hearing on the antivivisection bills took place before the house health and sanitation committee, representatives of the various medical schools appearing against the bills. Among these were Drs. Alfred Stengel, David Riesman and A. E. Taylor, University of Pennsylvania; Seneca Egbert and Joseph McFarland, Medico-Chirurgical; R. A. Remington, Philadelphia College of Pharmacy, and State Veterinarian, C. J. Marshall.

Governor Favors Change in Medical Bill.—Governor Tener favors reconstructing the present medical bill. The provisions of the new measure will be substantially those of the Gerberich-Wasson measure now in the committee of health and sanitation in the senate. An amendment will be proposed to the bill to definitely fix the compensation of the examining board. This board will be composed of the state commissioner of health, the state superintendent of public instruction and five others to be appointed by the governor. Of these latter, there will be one member of each branch, regular, eclectic and homeopathic. The remaining two will not be members of the same school.

Philadelphia

Gift to Hospital.—The Rush Hospital for the Treatment of Consumption has been given $5,000 by Mr. John Wanamaker for the endowment of a free bed.

Elections.—The following officers for 1911 were elected at the last meeting of the Jefferson Hospital Clinical Society: president, Dr. Hobart A. Hare; vice-president, Dr. Frederick J. Kalteyer; secretary, Dr. Elmer H. Funk; treasurer, Dr. Clarence D. Smith, and executive committee, Drs. Aller G. Ellis, P. Brooke Bland, Edward J. Klopp and Edward J. G. Beardsley.

Gifts to College of Physicians.—At the stated meeting of the College of Physicians, April 5, Dr. John B. Shober read a memoir of the late Dr. George Couvier Harlan, after which a portrait of Dr. Harlan was presented to the college on behalf of the daughter, Mrs. Harry Post Mitchell.——A portrait of Dr. James Tyson was *also presented by Dr. George A. Piersol* on behalf of the donors.——Another gift to the college was an acupuncture needle and a lancet, used by native Korean physicians.

Dr. Scott Memorial.—Ten thousand dollars has been contributed to the University of Pennsylvania to establish a memorial to the late Dr. J. Alison Scott, adjunct professor of medicine in that institution. This memorial will take the form of a fellowship for medical research. Of the interest money $200 will be spent each year to help some medical student to finish his course, while the remainder will be reinvested until the entire sum is large enough to support a physician, able to do research work.

Important Notice to Physicians.—The following postal card notice was sent to all physicians of the city from the Registration Office of the Bureau of Health:

> The Pennsylvania State Department of Health, conjointly with the Philadelphia Bureau of Health, is taking a block census of children under 2 years of age born in Philadelphia. This work will henceforth continue regularly. Where unregistered births are discovered an immediate prosecution will be instituted against the physician, midwife, institution or person found to be negligent. This notice is intended as a warning—that the law requiring the registration of all births within ten days of their occurrence will be absolutely enforced in every instance. Stillbirths must be registered both as births and deaths.

Efforts to Overturn Pure Food Laws.—An attempt to overthrow the pure food laws of the state by permitting the use of sulphur dioxid in the manufacture of candy, was disclosed in a bill presented to the legislature by Representative Edwin M. Abbott, March 30. This bill makes the second attempt within a short time to overturn the pure food laws. The first bill introduced by Senator James P. McNichol provided that saccharin might be used in "soft drinks," while the Abbott bill amends the present pure food law by allowing the use of sulphur dioxid in the manufacture of candy.

GENERAL NEWS

Association for the Study of Epilepsy.—The National Association for the Study of Epilepsy and the Care and Treatment of Epilepsy will hold its annual meeting in St. Louis, June 16, under the auspices of the St. Louis Medical Society. This date has been set so that members may attend the Denver meeting of the American Medico-Psychological Association, and still reach Los Angeles in ample time for the meeting of the American Medical Association.

Threatens Marine Hospital Surgeon.—The surgeon general of the Public Health and Marine-Hospital Service has received a report from Surgeon Henry D. Geddings, on duty at Naples, to the effect that his life has been threatened because of his activity in the cholera situation. Geddings has received anonymous letters threatening his life and has been pelted with vegetables and decayed fruit. The situation became so disagreeable that the authorities of Naples have furnished him with a guard.

Prevention of Infant Mortality.—The second annual meeting of the American Association for the Study and Prevention of Infant Mortality will be held in Chicago, November 16-18. The work of the association will be in six sections: Midwifery, Dr. Mary Sherwood, Baltimore, chairman; eugenics, Prof. H. O. Jordan, University of Virginia, chairman; public school education, Dr. Helen C. Putnam, Providence, R. I., chairman; housing, Mr. Lawrence Veiller, New York City, chairman; milk, Prof. E. O. Jordan, University of Chicago, chairman; and rural communities, Dr. Edward W. Saunders, St. Louis, chairman. Special reports will be made on the relative value of existing agencies in infant welfare work and on the work being carried on in this country, Great Britain and continental Europe in the prevention of infant mortality.

International Medical Congress.—The Seventeenth International Medical Congress will be held in London in the summer of 1913, the exact date being fixed by the permanent committee which will assemble in London, April 21 and 22, under the presidency of Dr. Frederick W. Pavy, *London. At this meeting* a list of the sections of the congress will be arranged. Any wishes or suggestions concerning the arrangement of this list may be sent, up to April 1, to the secretary of the permanent committee, Prof. H. Burger, Vondelstraat, I, Amsterdam, Holland, or to the bureau of the committee, Hugo de Grootstraat, 10, The Hague, Holland. The committee will also be glad to receive before that date, any information or suggestions regarding the organization of the congress. This is the first time any international medical congress has been organized with such broad preliminary work, and it is hoped to get out of ruts and the influence of traditions and to make the congress represent the advance of science in congresses as well as in the science for which the meeting stands. The appeal of the committee for suggestions should be heeded. Dr. John H. Musser, 1927 Chestnut Street, Philadelphia, the American member of the permanent commission, expects to attend the meeting of the commission in London and will be glad to present any suggestions made by the readers of THE JOURNAL.

FOREIGN NEWS

Sanitary Progress in Latin America.—The little island of Curaçoa, just north of the most northern point of South America, is a gateway to Porto Rico and the Panama Canal Zone; consequently it is satisfactory to learn that the colonial government has made strenuous efforts to exterminate rats. The war of extermination was instituted last year when plague appeared at the two principal ports of Venezuela to the south. Cable despatches also state that the city of Guayaquil, the main port of Ecuador on the Pacific Coast, has engaged engineers to install a new drainage and water-supply system and rebuild portions of the city to place it in first-class sanitary condition. Eight millions have been appropriated for this purpose. The way in which Buenos Aires is handling the rat question was described in these columns March 18, page

Rio de Janeiro has been transformed in the last few years so that it now ranks among the healthiest cities in the world. Oswaldo Cruz, who had charge of the sanification of Rio, is now engaged in a similar task at Para, at the request of the city of Para, which is near the mouth of the Amazon River and is the headquarters of the Brazilian rubber trade. Cruz took with him ten leading sanitarians besides an office force and seventy aids. The entire force is under contract to the state of Para and the task of sanification is now well under way. In all the reports of the progress of sanitation in Latin America there is always some reference to the "Americans" having blazed the way—it is certainly curious how the countries to the north and south of the United States unanimously restrict the term "Americans" to the people of this country. The people of the United States have never arrogated to themselves the exclusive title of "Americans," but our neighbors north and south seem to have voluntarily thus crowned us.

Deaths in the Profession Abroad.—In addition to those already mentioned in our foreign correspondence, the following eminent physicians have died recently: J. dos Santos, Viscount de Ibituruna, the Nestor of the physicians at Rio de Janeiro and long a leader in preventive medicine, president of the Brazilian Liga contra a tuberculose, formerly president of the city council and of the board of public health, aged 83.——C. van Gauwenberge, professor of gynecology and obstetrics at the university of Ghent.——At Lima, Peru, F. A. Suter, professor of surgery, aged 37. He was called to this post from Switzerland in 1908.——W. F. Sprimon of Moscow, founder in 1881 and editor of the leading Russian medical monthly, *Medizinskoe Obozrenie*.——M. Nery, professor of nervous and mental diseases at the University of Rio de Janeiro and on the editorial staff of the *Brazil Medico*.——C. A. MacMunn of Wolverhampton, Eng., well known for his physiologic research, especially the application of the spectroscope to physiology, author of "The Spectroscope in Medicine" and of other works on physiologic and pathologic chemistry, aged 58.——Arthur Frame Jackson, M.B., 1909, Cambridge and Liverpool; D.T.M., 1910, Liverpool; a young medical missionary of great promise, a member of the staff of the Presbyterian Hospital, Mukden, Manchuria, and in charge of the section of that city in which 80 per cent. of the deaths from bubonic plague have occurred, contracted that disease January 23, and in spite of injections of Yersin's serum, and all that medical science could do, died January 25, aged 26. At the memorial services held in the British Consulate General, Mukden, February 1, Hsi Liang, viceroy of Manchuria, paid the following tribute to the work and memory of Dr. Jackson:

> We have shown ourselves unworthy of the trust laid on us by our emperor; we have allowed a dire pestilence to overwhelm the sacred capital. His majesty the king of Great Britain shows sympathy with every country when calamity overtakes them. His subject, Dr. Jackson, moved by his sovereign's spirit, and with the heart of the Savior, who gave his life to deliver the world, responded nobly when we asked him to help our country in its need. He went forth to help us in our fight; daily, where the pestilence lay thickest, midst the groans of the dying, he struggled to cure the stricken, to find medicine to stay the evil.
>
> Worn by his efforts, the pestilence seized on him, and took him from us, long ere his time. Our sorrow is beyond all measure, our grief too deep for words. Dr. Jackson was a young man of high education and great natural ability. He came to Manchuria with the intention of spreading medical knowledge and thus conveying untold blessing on the eastern peoples. In pursuit of his ideal he was cut down. The Presbyterian mission has lost a worker of great promise, the Chinese government a man who gave his life in his desire to help them.
>
> O, spirit of Dr. Jackson, we pray you intercede for the 20,000,000 people in Manchuria and ask the Lord of heaven to take away this pestilence, so that we may once more lay our heads in peace on our pillows. In life you were brave, in death you are an exalted spirit. Noble spirit, who sacrificed your life for us, help us still and look down in kindness on us all.

LONDON LETTER

(From Our Regular Correspondent)

London, March 25, 1911.

A Novel Doctrine of Ventilation

At the Institution of Heating and Ventilating Engineers, Mr. Leonard Hill, the eminent physiologist, described a remarkable series of experiments which he and his staff at the London Hospital have made, and which have led to a doctrine of ventilation that is a complete revolution. He began by referring to evidence which he gave before a royal commission on the conditions of weaving sheds. In these sheds there must be a high degree of humidity. The health authorities insist that the percentage of carbon dioxid must not rise above the usual amount allowed, say 10 parts in 10,000, but the work people want the sheds to be shut up and "stew in their own juice," so to speak. They wanted to get the requisite humidity from their own breaths rather than from admission of warm vapor. Now, curiously, the regulations, while forbidding more than a certain amount of carbon dioxid, did not prescribe any limitation of the wet-bulb temperature. But Mr. Hill found that carbon dioxid does not do any harm whatever, while a wet-bulb temperature of 75 degrees is very bad and ought not to be tolerated in any factory. All the current teaching of the hygiene of ventilation runs on the chemical purity of the air; but according to Mr. Hill the essential thing in ventilation is heat, not chemical purity. It does not matter if there is 1 per cent. more carbon dioxid and 1 per cent. less of oxygen. In the worst ventilated rooms there is not 1 per cent. less of oxygen. The only effect of an excess of carbon dioxid is to make one breathe a little more deeply. A much higher amount has to be attained to have any toxic effect. As to organic impurities derived from respiration, there is no physiologic evidence of their toxicity or that they are of any importance except as an indicator of the number of bacteria in air. Chemical purity of the air is desirable in order to diminish the chance of infection, but in halls and theaters there is very little chance of preventing infection from persons who sneeze or cough out thousands of bacteria. Even when a man is speaking, he is spraying out bacteria in front of him. The really important thing is immunity to such bacteria. In the case of water-borne disease we can prevent infection but not in the case of air-borne disease. The way to keep air best from the physiologic point of view is shown by the following experiment performed by Hill at the London Hospital: Into a small chamber which holds about 3 cubic meters he put eight students and sealed them up. They got into the chamber joking and lively. At the end of half an hour the wet-bulb temperature had risen to 85 F. They had ceased to laugh and joke and their faces were congested. The carbon dioxid had gone up 4 or 5 per cent. and the oxygen down to a corresponding extent. Hill then put on three electric fans and merely whirled the air about just as it was. The effect was like magic; the students at once felt perfectly comfortable, but immediately the fans stopped they felt as bad as ever. In another experiment, a man in the chamber breathed through a tin of soda lime so that he got no carbon dioxid. When the wet-bulb temperature rose to 85 degrees sweating and discomfort came on, just as in the first experiment, and when the fans were turned on he got the same relief. Then a bag containing carbon dioxid was connected with the chamber and enough of the gas was admitted to raise the percentage of carbon dioxid to 2 per cent. The man in the chamber felt no ill effects whatever and even did not know that the gas had been admitted, but he was observed to breathe more rapidly. These experiments, Hill asserts, show that all the discomfort from breathing air in a confined space is due to heat and moisture and not to carbon dioxid. Even after forty-five minutes in the chamber there were no after-effects such as headache. In a crowded room, the air is at the body temperature and there is no circulation; therefore it becomes saturated with moisture and we have no means left of keeping the body temperature down. We cannot radiate heat because we are of the same temperature. We cannot lose heat by evaporation because the air is entangled among our bodies and cannot get away. Then the heat-regulating mechanism is strained and in order to keep the body temperature down the heart has to beat very much faster and we feel miserable, but as soon as the air is made to move relief is given. Mr. Leonard Hill concludes, therefore, that when it is not possible to keep the air of a building up to the chemical standard of purity laid down in the text-books the proper course is to keep the air moving. In weaving sheds the wet-bulb temperature must be kept below 75 F. There are mines in Cornwall in which the wet-bulb temperature is often up to 90 F. and the men do not do an hour's work in the day; they drink enormously and pour the sweat out of their boots. The open air treatment that is so much talked about is not, he declares, a matter of fresh air, it is merely the constant cooling of the body by the circulation of air which makes us eat more and be more active. This leads to a general strengthening of the body because the blood is not only circulated by the heart but by every muscle in the body. There cannot be efficient circulation without constant movement and activity. If there is constant cooling by ventilation then a person is kept more active and the general health is improved.

Sir Francis Galton's Bequest for the Study of Eugenics

Sir Francis Galton, notice of whose death appeared in The Journal, February 4, p. 359, made a remarkable bequest of residuary estate, which is expected to amount to $325,000, for the advancement of eugenics, the science of race improvement, which he initiated in 1901. The money is to be used to endow a "Galton Professorship of Eugenics" at the University of London, with a laboratory and a library attached thereto. According to the words of the testament: "It shall be the duty of the professor to pursue the study and further the knowledge of national eugenics, that is, of agencies under social control that may improve or impair the racial faculties of future generations physically and mentally." The professor will be expected to collect material bearing on eugenics, to provide, under appropriate restrictions, information to private individuals and public authorities concerning the laws of inheritance in man; to urge the conclusions as to social conduct which follow from such laws, and to extend the knowledge of eugenics by instruction, publications, lectures and experimental or observational work. Sir Francis Galton left property to the gross value of $575,000. Thus, he left more than half of his estate for the advancement of the subject he had so much at heart. He also expressed the desire that the first holder of the chair should be Prof. Karl Pearson, the well-known protagonist of biometric methods, who shall have liberty to continue his biometric laboratory at University College.

The Small-Pox Epidemic

The small-pox epidemic in London appears to be at an end. No fresh cases have been reported for a fortnight. An outbreak of small-pox occurred at Bury in Lancashire, and there are now twenty-five patients in hospital. The outbreak has been traced to a mill in which all the affected people were employed. The mill has been closed in consequence of the operatives declining to work. The warps and weft in several looms have been ordered to be destroyed and about 3,000 finished pieces of cloth have been disinfected.

MANILA LETTER

(From Our Regular Correspondent)

MANILA, Feb. 13, 1911.

Effect of Tropical Climate on White Men

For all time, the discussion of any phase of the general topic, the effect of the tropics on the white man, doubtless will attract more or less attention. This effect, which is at once apparently so evident, and yet at the same time so difficult to prove absolutely, is bound to give rise to a great deal of scientific, semiscientific and popular discussion. That one does undergo a change in himself after coming to tropical Oriental countries is universally admitted. But whether this change is for good or bad in many cases might be open to doubt. A great deal depends on the personal element, one's former habits and environments and the habits, environments and associations which he falls into or acquires in the hot climate. For instance, for many Americans who are given to too much of the so-called American hustle, a temporary residence in the tropics is likely to prove directly beneficial. On first arriving in the tropics from a temperate climate a man finds himself burdened with a great desire for sleep—long hours of sleep at night and a nap after lunch. Any strenuous exercise quickly exhausts him, and tennis is very often the limit of his powers of exertion. This condition does not obtain usually more than three or four months, and he feels himself normal again, capable of much more exercise, and work ceases to be a burden, although in the meantime he has probably adjusted his activities to a slower pace.

The agents which are responsible for this effect, and for the more obscure and serious effects believed by many to be experienced by persons from temperate climates who remain in the tropics for a long time, are still unknown. The intense heat, the prolonged hot season, the glare of the tropical sun and the actinic rays of the tropical sun all have been indicted. Recent physical experiments made at the Bureau of Science, Manila, tend to rule out the actinic rays. In regard to the actinic rays, there have been made also in the U. S. Army in the Philippines, by the Tropical Diseases Board, a series of observations on soldiers wearing orange-red underwear. Cloth of this color had been supposed to be relatively impervious to the actinic rays of the sun. Hence, people wearing orange-red clothing would be almost immune to this supposedly injurious tropical agent. The following report has been made:

"During the quarter, the tests of the orange-red underclothing, which have been under way for over a year, were completed, and the work of compiling the great amount of data obtained from these observations was carried out by Captain James D. Phalen of the Medical Corps, who has submitted an extensive special report on the subject. A summary of the work is as follows:

"The test of the orange-red underwear and hat linings was undertaken as a result of recommendations by the Inspector-General of the Army. The garments were prepared at the Philadelphia depot of the Quartermaster Department, and were of a deep orange-red color. The shirts averaged one-fifth of an ounce heavier than the white ones worn by the controls. The orange-red drawers were of a different type from the white ones and averaged 1 1/5 ounces heavier. The garments faded materially on washing, especially if exposed to the sun while drying. However, the inner surface retained much of the dye, and it is not thought that the fading was so great as to destroy the value of the tests.

"It had been intended to equip 1,000 men with the special underwear and an equal number of controls with white, but, owing to inability to fit sufficient men from the 5,000 suits furnished, it was found impossible to equip over 500 with the orange-red garments. The tests were carried out under the immediate supervision of the following medical officers at the posts shown after their names: Major C. C. Collins, Fort McKinley, Rizal, P. I.; First Lieutenant C. L. McKinney, Camp Stotsenburg, P. I.; First Lieutenant H. A. Philips, Camp Jossman, Guimaras, P. I.; First Lieutenant C. D. Cowles, Jr., Zamboanga, Mindanao, P. I.

"The men wearing the special clothing and the controls wearing the white were taken from the same companies, which were equally divided in such a way as to make the two groups as nearly as possible equal in physique. Those with long tropical service, or who were exceptionally weak, were excluded.

"The experiment was kept up during the calendar year of 1909, and a summary of the results are as follows:

"(1) Weight:—There was a loss of weight during the year in both groups of men, more marked in the mid-year (hot season) weighings, a certain amount of the mid-year loss being made up by the end of December. The loss of weight at the mid-year observations was greater by an average of 1 pound for the orange-red group men than for the control group. At the end of the period of observation there was no difference of weight in the two groups.

"(2) Blood Examinations:—The result in both groups agreed in character if not in degree with those of Captain Wickline of the Medical Corps, showing an increase above normal in the number of red cells and a decrease in the percentage of hemoglobin, the hemoglobin index being necessarily still more diminished. The increase of red cells and the decrease of hemoglobin were both more marked in the orange-red group than in the controls. Both this change and the greater loss in weight, referred to above as the lower blood-pressure mentioned below, may have been due to increased perspiration on the part of the orange group during the hot season.

"(3) Blood-Pressure:—The blood-pressure of both groups fell during the hot season, the fall being slightly more marked in the orange-red group. In December the pressure in both groups returned to practically the original point.

"(4) Pulse, Temperature and Respiration:—These were taken after drill or other exercises, 8,000 observations being made. Averages for 1,500 observations are shown in the following table:

Orange-red group..........	98.792	91.2	22.3
White group.	98.780	90.9	21.3

"It will be seen that each is higher for the orange-red group than for the controls, but the differences are very slight.

"(5) Comparative:—Sick reports showed insignificant differences. The admissions per 1,000 and the days lost per 1,000 were, respectively, 508 and 3.526 for the special group, and 478 and 3.522 for the white group. The admissions per 1,000 for heat exhaustion were higher for the orange-red group, twenty-seven as compared with twenty-one for the controls.

"(6) Strength Tests:—Strength tests on men from the two groups showed nothing of value.

"(7) Symptoms Referable to Climate:—The two groups suffered about equally from these except as regards excessive perspiration, which was much more complained of by the men of the orange-red group.

"(8) Impressions of the Wearer:—Sixteen men preferred the orange-red garments, fifty-four had no choice between the colors, and the remainder, nearly 400, expressed an opinion adverse to the colored underwear. Fifty said it was hotter and 104 others stated that it caused more profuse perspiration. No organization commander saw any benefit from its use, and of sixteen officers who used it for a time, only one expressed approval.

"(9) Photographic Experiments:—Experiments showed that the campaign hat was as impervious to the rays affecting the photographic plate, without the orange lining as it was with it. The lining added materially to the opacity of the khaki cap. The differences in penetrability by actinic rays between a light skin and a dark Filipino were slight, and were entirely neutralized by one layer of khaki uniform cloth. The pigment of the darkest skin was found nowhere nearly so protective as was the orange-red garment.

"(10) Temperature Experiments:—Extensive experiments, both on and off the body, showed that, when exposed to the sun, the temperature was greater beneath the orange-red material than it was beneath similar white material. The same was found to be true when both materials were overlaid by khaki cloth.

"(11) Moist Heat Experiments:—These were carried out at Los Banos in a room ranging from 90 to 98 F. and with the atmosphere saturated with moisture. Men remaining four hours in this room lost greatly in weight and had a marked rise in temperature, with acceleration of pulse and respiration and fall in blood-pressure.

"From the results of the whole test and the experiments the conclusion was reached that the physiologic effects of the climate in the Philippines can be and probably are produced by moist heat without the aid of the sun's actinic rays, and no evidence was found that the sun's rays alone could or did produce these effects. On the contrary, the test underclothing added materially to the burden of heat which the system was compelled to endure and which is probably the chief cause of tropical deterioration. Even if the actinic rays have any influence whatever on the system, it is believed that they are sufficiently excluded by the khaki uniform and the campaign hat."

PARIS LETTER

(From Our Regular Correspondent)

Paris, March 24, 1911.

Statistics of Cancer

Dr. Jacques Bertillon, of the service of municipal statistics of Paris, on March 24 made an interesting communication on the statistics of cancer to the Académie de médecine. Drawing his material from the sanitary statistics of the communes published within the last three years by the interior department, he showed that it was easy to mark out on a map of France the region where cancer is frequent in the country and that where it is rare. If one draws a line from Caen to Angers, another from Angers to Dijon, and a third from Dijon to Mézières, in the quadrilateral formed by these three lines and the northern frontier are included all the departments which are most affected by cancer. Outside of this quadrilateral, on the other hand, except for La Vendée and l'Isère, are the departments where cancer is a third or a fourth as frequent. This fatal quadrilateral corresponds quite closely to the chalky basin of which Paris is the center. On the southwest, one may trace another quadrilateral as much exempt as the other is affected, by drawing a line from La Rochelle to the Rhône to the south of Lyons. The quadrilateral formed by this line, the Rhône, the Pyrénées and the two seas does not contain a single department where cancer is notably frequent. These statistics concern only the communes having less than 5.000 inhabitants, that is to say, the country; nevertheless, the distribution of cancer in French cities is identical with its distribution in the country.

In general, cancer is more frequent in the northern countries of Europe (England 91 deaths per year per 100,000 inhabitants, Norway 100, the Netherlands 101) than in the center of Europe (Prussia 71, Austria 78, France 76) and much more rare in the countries bordering on the Mediterranean (Spain 48, Italy 61, European population of Algeria 32). Its frequency, however, is increasing in all countries without exception. In England it has almost trebled within fifty years. The statistics of the other countries do not go back so far, but show at least as rapid an increase. The statistics of Paris show that cancer is not increasing in subjects under 55. Cancers of the stomach and the alimentary canal in general are increasing, but not cancers of the breast or of the genital organs. Is this state of things to be attributed to our diet? This is a point which cannot be answered. At all events, cancer is at present one of the most cruel scourges of humanity. In England it causes almost as many deaths (34,053 in 1909) as pulmonary tuberculosis (38,639). In France it caused 30,124 deaths in 1908.

The Statistics of the Public First-Aid Service

The public first-aid service of the prefecture of police has just compiled the statistics of the work done during 1910. The first-aid pavilion established on the borders of the Seine received 321 persons (247 men and 74 women) who were rescued from the river; of these three were not revived; 132 had thrown themselves into the water intentionally. In the first-aid stations of Paris 268 wounded and 12 sick persons were cared for. In the suburbs 78 wounded and 17 sick were cared for. The litters of the various stations of the arrondissements were used 661 times. The ambulances installed at the time of the ceremonies and public celebrations received 302 persons, 120 at the national festival, 62 during carnival.

Personal

Dr. Séverin Arloing, professor of experimental and comparative medicine at the Faculté de médecine de Lyon, and director of the veterinary school of that city, has just died suddenly. He was a correspondent of the Académie des sciences and a national associate of the Académie de médecine de Paris. His works on comparative pathology, some written by himself alone, some in collaboration with M. Chauveau, brought him a great reputation. In his latter years he devoted himself especially to research on tuberculosis.

Dr. Charles Debierre, professor of anatomy at the Faculté de médecine de Lille, has just been elected senator.

Measures Against Depopulation in Belgium

Serious inquietude is beginning to be felt in Belgium over the constant diminution of the birth-rate, which has been going on for some years. A bill has recently been proposed to punish by imprisonment of from one to three years, physicians, midwives and pharmacists who recommend means of abortion; also, to punish by imprisonment of from six months to three years and a fine of from $40 to $600 (200 to 3,000 francs) anyone who shall sell, put on sale or even privately offer drugs, instruments or objects intended to produce abortion, whether the attempt be effective or not.

Diminution of the Number of Abandoned Infants

According to the statistics communicated by M. Mesureur, director of the public charities (Assistance Publique) of Paris, the number of abandoned infants has diminished considerably, especially the number of abandoned infants from 8 to 15 days old. There were 1,500 such infants abandoned in 1900 and 1901; 1,300 in 1905, 1,100 in 1907 and 1908, and 1,000 in 1909, or a diminution of a third in ten years.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, March 17, 1911.

Personal

Dr. Seydel, extraordinary professor of legal medicine in Königsberg, celebrated the golden jubilee of his doctorate March 2.

Professor von Angerer, the body physician of the prince regent of Bavaria, was granted, on the occasion of the ninetieth birthday of the latter, a hereditary title of nobility.

Centennial of the University of Breslau

In August of this year the centennial of the University of Breslau occurs. In view of this circumstance, Dr. Paul Schottländer, a son of the well known publisher in Breslau, has contributed $62,500 (250,000 marks) for the aid of students and assistants of the Breslau university who are making tours for the purpose of investigation.

Prize Offered for Essay

A newspaper appearing in Frankfort called *Die Umschau* has offered a prize of $300 (1.200 marks) for the best work on the question "What do the inferior elements of the race cost the State and Society?"

Proposal to Establish a Department of Psychiatry in the Imperial Health Office

The well known psychiatrist, Professor Sommer of Giessen, has presented a petition to the Reichstag asking for the foundation of a department of psychiatry in the Imperial Health Office. The institution is to consist of a department for statistics and records of institutions, a department for clinical and forensic psychiatry, and a department for heredity and mental hygiene. Both the committee in charge of the petition and the government have characterized the plan as impracticable and so the proposition was merely referred to the imperial chancellor without comment.

Prize Articles on the Early Clinical Diagnosis of Cancer

The German central committee for cancer research has awarded prizes of $250, $125 and $75 (1,000, 500 and 300 marks) for the three best articles on the early diagnosis of cancer by clinical means which are suitable for distribution as circulars to practitioners. The prizes have been given in this order: Dr. Fischer-Defoy of Quedlinburg, Prof. Karewski, the well known surgeon of Berlin, and Dr. Hollmann of Solingen.

Discussions of the Reichstag Committee on the Antiquackery Bill

The further proceedings of the committee on the third section of this bill, namely, the forbidding of treatment by means of mystical processes, have increased the number of remarkable statements on the part of the conservatives and members of the center group on the value of the mystic methods of treatment. One conservative declared on the ground of thirty years' experience, that the so-called incantations (*Besprechen*) are of value for human beings as well as for animals. There occurred in connection with it a reflex action on the nervous system of the person who used the treatment. He had himself seen cases in which men who used incantations on animals, were themselves made to vomit. In his view there was a secret relation between the conjurer and the conjured, and there were secrets in nature which science so far is unable to explain. A member of the center group emphasized that the limits between faith and superstition were so difficult to draw that it is dangerous to attempt to define them. Naturally these grotesque views are held up to ridicule in the papers, and this has had the favorable effect that the representatives of the conservatives and of the central party are more reserved in their expressions. It is to be hoped that the passage of the law against quackery will be promoted thereby.

Proposed Settlement of the Insurance Physician Question

The committee of the Reichstag which has the new insurance legislation under consideration, has, after much debate, reached a determination of the relations between physicians and the Krankenkassen, the most favorable to physicians of any that have so far been made. Whether the committee's report will be accepted by the house, remains to be seen. The most important paragraphs are as follows:

The relations between the Krankenkassen and the physicians shall be determined by a written contract. The Kasse (sick benefit club) may, except in urgent cases, refuse to pay other physicians. So long as it does not distinctly increase the burden of the club, it shall give its members free choice of at least two physicians. If the insured will pay the extra cost he shall have the right to choose among the physicians appointed by the clubs. The club may, however, decide that the patient can change his physician during the business year, or during the treatment of the same insurance case, only with the permission of the management. If the care of the sick by any sick benefit club is seriously menaced by the fact that the club cannot make a contract with a sufficient number of physicians or because the physicians do not keep their contract, the chief insurance officer may empower the sick benefit club to pay cash instead of furnishing nursing or medical care, to the extent of two-thirds of the average amount of their legal fund for sickness. The chief insurance office may at the same time determine: 1. How the condition of the person who is to receive the service shall be evidenced otherwise than through a physician's certificate. 2. That the club may continue its services as long as satisfactory evidence is furnished or withhold them until such evidence is provided. 3. That the club's duty to furnish service shall lapse if no sufficient evidence is brought within one year after the occasion for service arises. 4. That the club may send those who need medical care to a hospital even if the conditions of Section 199 (Par. 2) are not fulfilled. The club may appeal from the decision of the insurance office to the superior government officers. Section 381 permits the management to provide hospital treatment only through certain hospitals. Certain hospitals, especially those devoted to charity, may be excluded only for important reasons. Section 382 provides: If the hospital or medical treatment provided by any Krankenkasse is insufficient, the chief insurance office may direct that these services shall be furnished by other physicians or hospitals. Section 383 directs that when the Krankenkasse does not obey this order the chief insurance office may provide what is necessary at the expense of the club.

Campaign Against Sensationalism in the Press

The energetic efforts of many people to repress obscenity in language and pictures has been happily extended to the suppression of exaggerated sensational news. The Verband der rheinisch-westfälischen Presse has published an announcement in which the tendency of many newspapers to provide the public sensational news is criticized and reform emphatically urged. The reports of sensational court trials should be condensed to the extreme, as experience shows that unstable minds are easily prompted to the commission of similar crimes by reading such news. The same is true with regard to accounts of crimes, especially those of a sexual nature. Further care should be taken to avoid the collection of items regarding crime in a single number, so that the reader may not lose the sense of the detestableness of such things, and especially that the idea may not be aroused in the mind of the young that deeds so common are inevitable.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, March 13, 1911.

Increase of Rhinoscleroma in Hungary

Acting on a suggestion thrown out at the last international medical congress in Budapest, a committee for the investigation of rhinoscleroma has been informally constituted in Hungary, and already it has found thirty-seven fresh cases, some of which have been reported on previously. At present it is not yet possible to state whether actual infection is present. Therefore steps have been taken to keep the known patients on a list. The only reliable treatment is surgical: excision of the scleromatous tissues, with subsequent packing of the resulting nasal cavities. The disease, at least in this part of Europe, affects chiefly young and otherwise healthy persons, and does not incapacitate them seriously except when the entire breathing through the nose is stopped.

A State Institution for Infants and Mothers

In compliance with a generous wish of the old emperor, who is extremely fond of children, a large amount of money which had been originally intended for public expenditure has been turned to charitable purposes, especially for the erection of a large institution for the care of infants and for the instruction of mothers. The emperor himself has consented to accept the protectorship of the institute. The plan is to combine the following institutions: a postgraduate school for pediatricians, a school for special infants' nurses, a mothers' school and a school for children with moral and psychic defects, besides a consulting department for diseased and healthy infants. Each district hospital will be invited to send two nurses to the nurses' school, where they will remain one-fourth to one-half year and will be instructed in all subjects pertaining to the care of infants, in health and disease.

Thus in a couple of years a large number of fully trained children's nurses will be available all over the country. Furthermore, trained midwives will be received as pupils in these classes. They will be the chief aid of the doctors in the country, where mothers so often rely on the counsel of the "wise women" in regard to the feeding of babies. It is hoped that they will also be a useful means of propagating breast-feeding. Also the matrons and nurses of orphans' institutes and foundlings' homes will be invited to attend these classes. Physicians desiring to become eligible to the directorship of similar institutions in the country will find opportunity to learn the duties of such a post. Mothers, as well as grown-up girls, will be invited to become pupils in the mothers' classes. They will learn the elementary principles of the practical care of children. They will come into contact with children and babies and mothers and thus will be prepared for duties which they might be called on to fulfil any day. Physicians and teachers will be in permanent attendance on this mother's counsel department. The school for defective children aims chiefly at making these individuals as capable as possible for earning part or whole of their living. At the same time, nurses who wish to take up this branch of their occupation will be able to spend a great part of the day with such persons.

It will be possible to train twenty nurses yearly as special nurses for defective children, forty hospital nurses for children, and as many midwives, while forty infants and twenty older children will be accommodated for periods of six weeks each. Thus about 500 children a year will pass through the hands of the pupils in the institution. A number of destitute mothers will be made able to earn their living as competent nurses, poor women will receive free advice for their babies, and a few hundred children will be under control, so that their lives will have better chances. And besides, the advantages offered to members of the medical profession are also very considerable.

Association News

EASTERN RATES

One Fare and a Half Granted on the Los Angeles Trip East of Chicago

In previous announcements about the Los Angeles Session, it was stated that the eastern railroad rates had not been decided. We are now able to announce that a rate of one fare and a half has been granted for the round-trip from points in the Central, Eastern and New England Passenger associations' territory to Chicago and return. The rate from Chicago to Los Angeles and return is $62.50, with $15.00 additional if one returns by one of the northern routes. Full information about rates, hotels, routes, trains, parties, etc., has been given in THE JOURNAL during the past weeks and will be repeated May 13 in the special illustrated number about Los Angeles.

No Program of Section on Dermatology

To the Editor:—The executive committee and the officers of the Section on Dermatology authorize its secretary to notify you of the postponement of the Section program and meeting for one year and that proper announcement be officially made by publication in THE JOURNAL. The action was taken at a meeting of the committee and officers of the Section in New York City, December 28, this action being the outcome of an insufficient number of papers. From eighty invitations issued requesting papers which were sent out in October only five papers were pledged, two being from men on the Pacific Coast.

H. R. VARNEY, Detroit, Secretary.

Miscellany

The Queer Things That Men Eat.—The primitive races of mankind eat many things that seem strange and repulsive to us, though not more so than some of our favorite dainties appear to them. Quoting from the circular of the Dresden Hygiene Exhibition, the *Scientific American* (March 11, 1911) says: At the end of the rainy season the Bushmen of South Africa go foraging, taking with them their wives and children and most of their earthly possessions. The men hunt, using arrows tipped with a poison which appears to be harmless when taken into the stomach. (The South American Indians assert that the curare which they use for this purpose makes the flesh of the game more digestible.) While the men hunt, the women dig edible roots with sharpened sticks. Caterpillars are collected, killed by crushing their heads and carefully packed in grass for future use. The aborigines of Australia live largely on the seeds of many species of grasses, for each of which they have a distinctive name. They also eat the seeds of various palms, many roots and bulbs and the gum exuded by trees. A sort of bread is made of the injua root, and a gruel of karanga seeds. The animal food of the Australians includes ants, caterpillars, cicadas and many other insects. A favorite dish, called tuinamba, is composed of pupa cases. The tent-like coverings which the psylla larvæ infesting the eucalyptus make for themselves out of the sweet and glutinous exudations of the leaves, and their own secretions, are dilligently collected and form a dainty which resembles manna and is called paralja. Another delicacy is the flesh of snakes which, with the exception of the liver, is too dry and tasteless to appeal to civilized palates.

The Physician and Public Health.—At all times, from the dawn of history, the highest function of the physician has been to guard those who entrust themselves to his care against the enemies of health, whether these come in the form of licentiousness, dissipation or disease, and for this service, mankind has always been willing to return a good compensation in both money and esteem. No man has ever been held in higher esteem in the world than he who could protect against impediments to health, who could ward off death when disease had broken through the lines of protection, and who could give relief from pain and disquietude. The world has bowed before him and even kings have honored him.—L. F. Flick, in *Interstate Medical Journal.*

"Stigma of Mentality."—A physician of Wisconsin, in sending an advertisement, part of which is reproduced below, writes: "I enclose a serio-comic but seriously intended advertisement that appeared in a local paper. It must be hard for some people to live under the 'stigma of mentality,' but it is indeed gratifying that there is an institution offering relief from this besetting sin."

> *This institution was established to supply* a public demand for a place where one could go without the stigma of mentality and receive treatment for those conditions requiring Physical correction. Open all the year.
> Physicians in Charge.

Rescuing the Baby.—In Chicago recently a woman adopted a clever expedient for saving her baby from burning when her dwelling caught fire. Awakened by the fire in her burning home, she quickly bundled her baby in pillows and blankets and dropped it from a second story window to the ground, a distance of nearly 20 feet. The child was uninjured.

Dropping the babe, well bundled in pillows and blankets, to the ground.—Courtesy of *Popular Mechanics.*

Marriages

J. M. HODGES, M.D., to Miss Frances McNeff, both of Detroit, March 20.

WALTER C. BROWNING, M.D., to Miss Anna Garrett, both of Philadelphia, recently.

ARTHUR J. SOMERS, M.D., to Miss Elizabeth Gerding, both of Portal, N. D., March 13.

HENRY B. TRIGG, M.D., Fort Worth, Tex., to Miss Nellie Roscoe Day of Rhome, Tex., March 22.

ERNEST ALBRECHT VICTORS, M.D., to Mrs. Nellie Temple Collier, both of San Francisco, March 17.

ELIOT ROUND CLARK, M.D., Baltimore, to Miss Eleanor Acheson Linton of Washington, Pa., March 21.

HOWARD LEON JAMESON, M.D., Philadelphia, to Miss Eunice Ostrum of East Mauch Chunk, Pa., January 14.

JOHN VANDOREN YOUNG, M.D., to Miss Rose Essie Kirkwood, both of New York City, at Passaic, N. J., March 16.

LEROY EDSON DOOLITTLE, M.D., Newberg, Ore., to Miss Bessie Kent of Duluth, Minn., at Spokane, Wash., March 20.

FREDERICK WILLIAM MAYER, M.D., St. Paul, Minn., to Miss Elsa Gertrude Hofman, at Jersey City, N. J., March 15.

ERNEST GEORGE BUTT, M.D., to Miss Olive May Vandruff, both of Redondo Beach, Cal., at Los Angeles, March 15.

J. RUSSELL VERBRYCKE, JR., M.D., Washington, D. C., to Miss Sophie English Barnes, at Washington, February 28.

Deaths

Edward Fitch Cushing, M.D. *cum laude*, Harvard Medical School, 1888; a member of the Ohio State Medical Association; died in Lakeside Hospital, Cleveland, March 23, ten days after an operation for the relief of intestinal obstruction, aged 48. After his graduation, Dr. Cushing served for three years on the resident staff of the Massachusetts General Hospital, and later was an intern in the Boston Lying-In Hospital, and the New York Maternity. After a year's study abroad he entered practice in Cleveland and became professor of pediatrics in the Medical Department of Western Reserve University, in the reorganization of which he was actively interested. He was a member of the Cleveland Board of Health, and one of the founders of the new Babies Dispensary and Hospital. He also reorganized at his own expense the *Cleveland Medical Journal* Company, of which he was president.

George Abbott, M.D. University of Buffalo, N. Y., 1852; a member of the Medical Society of the State of New York; vice-president and president of the Erie County Medical Society from 1864 to 1866; surgeon of the Fifty-Seventh Infantry N. G. S. N. Y. in 1854; colonel of the Ninety-Eighth New York Volunteer Infantry during the Civil War; died at his home in Hamburg, March 27, aged 84.

Jacob R. Spangler, M.D. Jefferson Medical College, 1874; a member of the Medical Society of the State of Pennsylvania; city physician of York in 1881, later a member of the city board of health, and for two terms a member of the school board; died at his home, March 21, from pneumonia, aged 60. At a special meeting of the York County Medical Society, March 22, action was taken on the death of Dr. Spangler.

James William Dodd Hancock, M.D. Long Island College Hospital, Brooklyn, 1898; of Brooklyn; a member of the Medical Society of the State of New York; assistant surgeon to the ear, nose and throat department of the Williamsburg Hospital and the Brooklyn Eye and Ear Hospital; who was injured in an automobile accident near Jamaica, March 17, died in St. Mary's Hospital, March 22, aged 40.

Silas Springer Tam, M.D. University of Mobile, Alabama, 1894; formerly a member of the American Medical Association; a member of the Medical Association of the State of Alabama; local surgeon for the Mobile, Jackson and Kansas City railroad for several years; died at his home in Mobile, March 18, some weeks after an appendicitis operation, aged 39.

William Edward Hibbard, M.D. New York University, New York City, 1889; a member of the American Medical Association, and American Academy of Ophthalmology and Otolaryngology; formerly of Providence, R. I.; a specialist on diseases of the eye and ear; died in his home in Pasadena, Cal., March 16, from the effects of burns received accidentally, aged 45.

Charles More Stewart, M.D. Trinity Medical College, Toronto, 1897; M.R.C.S., England, 1902; an ear, nose and throat specialist of Toronto; for a time superintendent of the Ottawa General Hospital; while riding in Toronto, March 25, was thrown from his horse in front of a street car and instantly killed, aged 38.

William Clarkson Hastings, M.D. Pulte Medical College Cincinnati, 1888; a member of the American Medical Association; formerly a resident of Portland, Ind., and first superintendent of schools of that place; died at his home in Seattle, Wash., March 18, from heart disease, aged 58.

Isaac Smith Cramer, M.D. College of Physicians and Surgeons, New York City, 1854; a member of the Medical Society of New Jersey; and treasurer of the Hunterdon County Medical Society; and surrogate of the county in 1889; died at his home in Flemington, March 27, from heart disease, aged 77.

Henry Frederick Klenke, M.D. New York University, New York City, 1892; for several years surgeon of the New Haven (Conn.) fire department, and school physician; formerly captain in the Governor's Foot Guards; died in the New Haven Hospital, March 22, from acute nephritis, aged 43.

Frank Darwin Smith, M.D. Missouri Medical College, St. Louis, 1880; a member of the Ohio State Medical Association; a member of the staff of Engleside Hospital, Canton; died at his home in Hartville, O., March 13, from occlusion of the coronary artery due to atheroma, aged 57.

Fred W. Slocum, M.D. Syracuse (N. Y.) University, 1882; a member of the American Medical Association and Syracuse Academy of Medicine; for many years a member of the Syracuse pension examining board; died at his home in Camillus, N. Y., March 16, from nephritis, aged 52.

Sampson A. Ayo, M.D. Tulane University, New Orleans, 1899; a member and one of the councilors of the Louisiana State Medical Society; and a member of the State Board of Health; died at his home in Thibodaux, March 11, from pleuropneumonia, aged 38.

Benjamin Thompson, M.D. Pennsylvania Medical College Gettysburg, 1851; formerly a member of the American Medical Association; local surgeon of the Baltimore and Ohio Railroad at Landenberg, Pa.; died at his home in that place, recently, aged 83.

William Jennings Headrick, M.D. University of Louisville, Ky., 1876; a member of the Louisiana State Medical Society; and local surgeon of the Houston, East and West Texas Railway; died at his home in Logansport, Nov. 2, 1910, from paralysis, aged 63.

Benjamin Dudley Williams, M.D. University of Louisville; Ky., 1884; a member of the American Medical Association; president of the Calhoun County Medical Association; died at his home in Oxford, Ala., March 12, from pneumonia, aged 57.

Lorenia Kemble (license, years of practice, Ind., 1897); for thirty-five years a practitioner of South Bend; died in St. Joseph's Hospital in that city, February 17, eleven days after an operation for carcinoma of the uterus, aged 62.

Charles W. Kinnison, M.D. Starling Medical College, Columbus, O., 1891; of Oak Hill, W. Va.; died suddenly, March 27, from heart disease, on a Chesapeake and Ohio train, while en route to Johns Hopkins Hospital, Baltimore, aged 44.

William Clark Cooper, M.D. Albany (N. Y.) Medical College, 1881; College of Physicians and Surgeons, New York City, 1884; obstetrician to Samaritan Hospital, Troy, N. Y.; died at his home in that city, March 17, aged 52.

George Canning Howard, M.D. Dartmouth Medical School, Hanover, N. H., 1865; formerly of Lawrence, Mass.; a member of the Massachusetts Medical Society; surgeon of volunteers during the Civil War; died at the home of his son in North Attleboro, Mass., March 19, from diabetes.

Nathaniel Leo Niles, M.D. Harvard Medical School, 1905; a member of the Providence, R. I., Medical Society; radiologist to St. Joseph's Hospital, Providence; died at his home in that city, March 23, from carcinoma of the stomach, aged 34.

Fred C. Miller, M.D. Minneapolis College of Physicians and Surgeons, 1899; a member of the Minnesota State Medical Association; health officer of Olivia; died at his home in that city, March 19, from pneumonia, aged 42.

Arnett Phillip Boston, M.D. Tulane University, New Orleans, 1877; a specialist on diseases of the eye, ear, nose and throat; of Alice, Tex.; died at his old home in Beech Grove, Ky., March 16, from cerebral hemorrhage.

Ledyard Verdine Lewis, M.D. Rush Medical College, 1870; of Sun Prairie, Wis.; a member of the American Medical Association; died at his winter home in Redlands, Cal., March 19, from cerebral hemorrhage, aged 65.

Robert W. Cooper, M.D. Michigan College of Medicine and Surgery, Detroit, 1892; formerly of Milford, Mich.; died at his home in Kingston, Mich., March 11, from brain abscess following influenza, aged 47.

Edward R. Aiken, M.D. Albany (N. Y.) Medical College, 1868; for more than thirty years a practitioner of Perry, Ia.; died at the home of his son in Aiken, Neb., March 18, from arteriosclerosis, aged 65.

Arthur Henry Bigg, M.D. Detroit (Mich.) Medical College, 1881; a member of the American Medical Association; and Detroit Academy of Medicine; died at his home in Detroit, March 17, aged 69.

Elbert Goodman Van Orsdell, M.D. Albany (N. Y.) Medical College, 1902; a member of the Medical Society of the State of New York; died at his home in Brooklyn, March 25, from pneumonia, aged 40.

Gilbert H. Tollington, M.D. College of Physicians and Surgeons, Chicago, 1885; a specialist on diseases of the eye; died at his home in Clear Water, Minn., February 12, from chronic nephritis, aged 48.

John Holin, M.D. College of Physicians and Surgeons, Keokuk, Ia., 1879; a member of the American Medical Association; died at his home in Cowden, Ill., March 18, from pneumonia, aged 65.

Mozark Jenkins, M.D. University of Vermont, Burlington, 1884; a member of the Medical Society of New Jersey; died at his home in Trenton, March 19, from laryngitis, aged 55.

Christopher William Flock, M.D. Victoria College, Coburg, Ont., 1856; for twenty years a practitioner of Nebraska; died at the home of his son in Emerson, March 11, aged 82.

Philander Tabor (license, Iowa, years of practice, 1887); for fifty-four years a resident of Independence, Ia.; died at the home of his son in that place, March 21, aged 93.

Willard Warren Ruggles, M.D. New York Homeopathic Medical College, New York City, 1908; died at his home in Brewster, N. Y., March 7, from typhoid fever, aged 31.

George Walker Bull, M.D. Bellevue Hospital Medical College, 1873; an ophthalmologist; formerly a resident of New York City; died in Paris, France, January 1.

Joseph Hartman Armitage, M.D. McGill University, Montreal, 1886; died at his home in Waterloo, Ont., January 18, from fracture of the spine, aged 50.

Lewis K. Esrey, M.D. Hahnemann Medical College, Philadelphia, 1888; died in his office in Philadelphia, March 24, from heart disease, agen 68.

William John Hare, M.D. Bellevue Hospital Medical College, 1885; died suddenly at his home in Detroit, March 23, from heart disease, aged 52.

Alexander C. Taylor, M.D. University of Pennsylvania, Philadelphia, 1850; died at his home in Vineland, N. J., March 22, aged 86.

William T. Risque, M.D. Kentucky School of Medicine, Louisville, 1856; died at his home in Paynes Depot, Ky., March 24, aged 83.

"The Propaganda for Reform"

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

Are Retail Pharmacists Waking Up?

While it is probably true that the physician's insufficient knowledge of drugs and of their use has been the chief cause for the growth of the proprietary specialty business, the pharmacist's inability to compound physicians' prescriptions properly has also been a potent cause for the prescribing of ready-made mixtures. Rancid or poorly made cod-liver oil emulsions have persuaded many a physician to prescribe Scott's Emulsion or some similar nostrum. Gritty ointments and turbid eye-drops have induced specialists to use ready-made preparations or to do their own dispensing. A program of a meeting of pharmacists—the Philadelphia Branch of the American Pharmaceutical Association—however, gives hopes that pharmacists are making serious efforts to improve professionally.

While the programs of meetings of retail pharmacists are often devoted to price protection, window trimming and the proper handling of cigars (live commercial topics, it is true), the meeting of the Philadelphia branch was devoted to a discussion of sterilization and its need as applied to pharmaceutical compounding. It also appears that the branch has a special committee whose function it is to arouse the interest of pharmacists throughout the country to the necessity of devising reliable methods for the preservation of galenicals, and also to the need of establishing a time limit for such pharmaceutical products as are known to deteriorate with age. Both of these subjects—the need in many cases of sterilizing pharmaceutical preparations and the necessity of giving proper attention to keeping qualities—are most important ones and their consideration cannot but be a benefit to professional pharmacists.

Therapeutically Suggestive Names for Medicines

While it is desirable that the name of a medicine should convey an idea of its composition, the full chemical names
medies are so long that their adoption is out
It would not be practicable, for instance, to
name for Ehrlich's new arsenic preparation.
xy-1-arseno-benzene hydrochlorid. In the

ronchiline, Genitone, Laxaphen, Mi-
osine, Ovaritone, Trigemin and Uri-septin. More recently, largely as a result of the influence of the Council on Pharmacy and Chemistry, manufacturers have adopted names which are more satisfactory, or, at least, that are a vast improvement over those used in the past. Thus, among the articles more recently passed by the Council are, Arsenoferratin, an organic compound of iron and arsenic; Carbosant, a carbonate of santalol; Digipuratum, a purified digitalis extract; Guaiacodein, a compound of codein and guaiacol; Tannismuth, a tannate of bismuth. These names are brief and to a certain extent descriptive of their composition. There is no basis for the excuse often given by exploiters of proprietary medicines for therapeutically suggestive names, namely, that it is impossible to coin names which are descriptive and yet sufficiently short and simple. Such disease-suggesting names as Antitussin, Pertussin, Migrainin, Somnos or Calmine should not be tolerated.

Similarity Between Nitrite and Acetanilid Poisoning

A physician recently wrote that a preparation of liquor sodii phosphatus compositus, when administered to a patient, produced symptoms that simulated acetanilid poisoning. The sample sent in by the physician was examined by the Association chemists who reported:

"Tests which would detect minute quantities of acetanilid failed to reveal the slightest trace of this substance. The odor of the solution was distinctly characteristic of oxids of nitrogen such as are produced in the decomposition of nitrates or nitrites. The presence of a small quantity of nitrate—a regular constituent of this preparation—was detected and also the presence of considerable quantities of a nitrite. Quantitative determinations showed the presence of an amount of nitrite equivalent to 2.9 per cent. sodium nitrite. It seems improbable that a nitrate used in the preparation of this mixture had decomposed to form a nitrite; it is more likely that a nitrite was used inadvertently. If this preparation was given in doses of 8 c.c. (2 fluidrams)—the U. S. P. dose for liquor sodii phosphatus compositus—the patient received 0.2331 gm. or three and one-half times the U. S. P. dose of sodium nitrite."

This note is published to point out the similarity between acetanilid and nitrite poisoning.

Postgraduate Surgical Clinics in America

To the Editor:—The increasing importance of surgery and the increase in the number of good surgeons in America is especially evident to one who has traveled extensively over this country and has had opportunity to observe closely and for long periods of time the work of America's surgeons. To a physician, nothing is more interesting than to visit the clinics of other physicians and this applies also to surgeons.

The custom is almost as old as medicine itself, and for many years numbers of American physicians have been going to Europe to visit the famous clinics for helpful suggestions and the pleasure of the trip. It is evident that the American surgical clinics are now finding a distinct place of their own. I recently returned from a two years' trip to some of the best-known clinics, where I gave time, energy and thought to the study of surgical diagnosis, technic, complications and after-treatment and others may be interested in a brief account of the opportunities for surgical study in America for graduate physicians, and description of places which seemed to be especially popular.

A constantly growing number of physicians and surgeons from all parts of the country are visiting the Mayo clinics at Rochester, Minn., the clinics of Johns Hopkins, the surgical clinic of the German Hospital in Philadelphia (Deaver) and the clinics of Murphy and Ochsner in Chicago. At these places I have seen from 25 to 100 men, many of whom have national reputations, enjoying the splendid clinics and the gracious hospitality extended by the surgeons to visitors. The chiefs of these clinics realize what a compliment it is for men to come from all over the continent to learn from them something definite and practical in the treatment of the sick. At some of these clinics there is a large comfortable room for the visitors, with a book of registry and books of reference: at the Rochester clinic there is a surgical club which meets in the afternoon and discusses the operations which have been performed in the morning. At all of these places one can find comfortable living accommodations.

At none of these clinics did I find the surgeons looking for money from their visitors and intimating that the visitors take a postgraduate course; no matter how long one stays, be it a day or a year, he is always welcome without price. If these leaders have been able to show a physician anything that will make him a more valuable man in his community, they are glad indeed. In this selfish and grasping age, such splendid courtesy and generosity are most commendable and stimulating, and there is no question that these clinics stand among the great achievements of our present civilization.

For those especially interested in gynecology, I found the clinics of Kelly at Baltimore, Bovee at Washington, Clark, Beyea and Baldy in Philadelphia, and Coe in New York, especially helpful. The surgical and gynecologic clinics of Boston are good and deserve a larger attendance. For practical work and the opportunity to do something in genito-urinary work I know of no place like Young's clinic at Baltimore.

The following up of the treatment of surgical cases is one of the things that a great many men want, and if a physician speaks to the operating surgeon and tells him that he wants to follow up the cases, the surgeon usually is only too glad to help and will introduce the visitor to the house officer. Arrangements can then be made to make the rounds with the house surgeon at an early hour in the morning.

Such has been my experience and taking this trip after five years of practical work, I found it most helpful and at the same time enjoyable. There are of course many other clinics where excellent work is done, but the clinics named are those that I, as well as many others, found especially stimulating.

F. W. Hornbrook, M.D., Boston, Mass.

Nasal Suction

To the Editor:—The value of negative pressure by suction in the treatment of diseases of the nasal sinuses has appealed to me for years and it has been my practice to insist that "secretions be aspirated and not blown" out of the nose following operations. When the vacuum pumps were first introduced I tried to use them, but without success until the past few weeks, as it was difficult to close the postnasal space. One day it occurred to me to have the patient take some water in the mouth and swallow it at command. This absolutely closed the space for a time and a little practice would keep it under control. This method so far has proved itself practical and is far ahead of all the other methods that I have seen or heard of. The effect is apt to be startling when it is first applied and it is well to advise caution regarding the water pressure as it is liable to produce dizziness. It is necessary, of course, for the patient to breathe through the mouth after the palate is raised in order to keep it in position. The technic otherwise is the same as is generally used.

Otis Orendorff, M.D., Canon City, Colo.

Cacodylate of Sodium in Coronary Disease

To the Editor:—Allow me to suggest the use of sodium cacodylate in coronary disease with resulting myocardial degeneration and its usual train of symptoms, such as: general edema, hypertrophied liver, pulmonary engorgement and a low hemoglobin content.

Its use in a case in which there was no history of any specific lesion was prompt and gratifying. An ampoule of the drug, containing 3 grains, was administered on alternate days, each dose being preceded by a small dose of cocain, to overcome the smarting which follows the injection of the drug under the skin. Salines sufficient to obtain a few watery stools were given each morning.

H. F. Gillette, M.D., Cuba, N. Y.

Correction in Analgesic Formula

To the Editor:—My attention has just been called to the analgesic formula in my contribution to The Journal, March 25, 1911, p. 863, which is so manifestly an error that I trust no one has adopted the quantities as given. The error must have occurred in dictation and subsequent transcription. The formula as published is dangerously meaningless. I intended it to read as follows:

℞ gm. or c.c.
Morphin hydrochlorid .... 0|01
Novocain .... 0|04
or
Scopolamin .... 0|0015
Normal salt solution............ 1|

Charles A. L. Reed, Cincinnati.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

HUBBES' NASCENT MERCURY TREATMENT OF SYPHILIS

To the Editor:—In The Journal, March 25, 1911, p. 934, reference is made to an article by Hubbes. Who is Hubbes? Can you give anything further on his technic of treatment of syphilis with nascent mercury? F. G. Carlson, Thornton, Iowa.

Answer.—Dr. Fritz Hubbes was formerly assistant at the dermatologic clinic at the University of Graz, Austria. We can add nothing to the description of the technic given in our abstract.

THE AUTOMOBILE SPEED QUESTION

To the Editor:—I wish you would advise me if there is a law permitting physicians, on accident or emergency calls, to exceed the speed limits of cities, and, if so, is there any official emblem designating such favor to them? D. Y.

Answer.—Some information on this subject will be found on automobile pages XXI and XXII of this issue.

It is a common practice for physicians to place insignia on their automobiles, front and rear. They are thus recognized by policemen and often favored in the matter of right of way. These signs usually consist of a device in which the red Geneva Cross is prominent; but, in deference to the wishes of the American Red Cross, there is not a little sentiment in favor of leaving the red Geneva Cross for the use of that organization. Congress has passed an act to limit its use.

As a substitute it has been proposed to use the green St. Andrew's Cross. Something on this subject will be found in the department of Queries and Minor Notes, in The Journal of Aug. 27, 1910, page 795, and one firm, which supplies such insignia for automobiles, is prepared to supply the St. Andrew's Cross in answer to this suggestion.

DENATURED ALCOHOL

To the Editor:—1. What is denatured alcohol? 2. Would it be safe for external use, as bathing, etc.?

G. D. Carnes, South Haven, Mich.

Answer.—1. Denatured alcohol is alcohol to which have been added certain materials which destroy its character as a beverage and render it unfit for medicinal purposes but which do not prevent its employment for industrial purposes. Denatured alcohol is exempt from the internal revenue tax laid on ordinary alcohol and is sometimes called tax-free alcohol. Under authority of an act of Congress, passed in 1907, the commissioner of internal revenue has prescribed that for general purposes alcohol known as completely denatured must be prepared by either of the following formulas: (A) To every 100 gallons ethyl-alcohol (of not less than 180 degrees proof) there shall be added ten gallons of approved methyl-alcohol and one-half gallon of approved benzin. (B) To every 100 gallons of ethyl-alcohol (of not less than 180 degrees proof) there shall be added two gallons of approved methyl-alcohol and one-half gallon of approved pyridin bases. The methyl-alcohol, benzin and pyridin intended for use as denaturants must be submitted for chemical test and must conform to certain specifications. In cases in which the above-named substances would render the alcohol unfit for certain industrial uses special denaturants have been authorized.

2. The safety of denatured alcohol for external use depends on the denaturing agent. If methyl-alcohol (wood spirits) is used for the denaturing, it may be absorbed to such an extent as to produce poisoning, such as blindness, etc.

Philander Tabor (license, Iowa, years of practice, 1887); for fifty-four years a resident of Independence, Ia.; died at the home of his son in that place, March 21, aged 93.

"The Propaganda for Reform"

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

Are Retail Pharmacists Waking Up?

While it is probably true that the physician's insufficient knowledge of drugs and of their use has been the chief cause for the growth of the proprietary specialty business, the pharmacist's inability to compound physicians' prescriptions properly has also been a potent cause for the prescribing of ready-made mixtures. Rancid or poorly made cod-liver oil emulsions have persuaded many a physician to prescribe Scott's Emulsion or some similar nostrum. Gritty ointments and turbid eye-drops have induced specialists to use ready-made preparations or to do their own dispensing. A program of a meeting of pharmacists—the Philadelphia Branch of the American Pharmaceutical Association—however, gives hopes that pharmacists are making serious efforts to improve professionally.

While the programs of meetings of retail pharmacists are often devoted to price protection, window trimming and the proper handling of cigars (live commercial topics, it is true), the meeting of the Philadelphia branch was devoted to a discussion of sterilization and its need as applied to pharmaceutical compounding. It also appears that the branch has a special committee whose function it is to arouse the interest of pharmacists throughout the country to the necessity of devising reliable methods for the preservation of galenicals, and also to the need of establishing a time limit for such pharmaceutical products as are known to deteriorate with age. Both of these subjects—the need in many cases of sterilizing pharmaceutical preparations and the necessity of giving proper attention to keeping qualities—are most important ones and their consideration cannot but be a benefit to professional pharmacists.

Therapeutically Suggestive Names for Medicines

Postgraduate Surgical Clinics in America

To the Editor:—The increasing importance of surgery and the increase in the number of good surgeons in America is especially evident to one who has traveled extensively over this country and has had opportunity to observe closely and for long periods of time the work of America's surgeons. To a physician, nothing is more interesting than to visit the clinics of other physicians and this applies also to surgeons.

The custom is almost as old as medicine itself, and for many years numbers of American physicians have been going to Europe to visit the famous clinics for helpful suggestions and the pleasure of the trip. It is evident that the American surgical clinics are now finding a distinct place of their own. I recently returned from a two years' trip to some of the best-known clinics, where I gave time, energy and thought to the study of surgical diagnosis, technic, complications and after-treatment and others may be interested in a brief account of the opportunities for surgical study in America for graduate physicians, and description of places which seemed to be especially popular.

A constantly growing number of physicians and surgeons from all parts of the country are visiting the Mayo clinics at Rochester, Minn., the clinics of Johns Hopkins, the surgical clinic of the German Hospital in Philadelphia (Deaver) and the clinics of Murphy and Ochsner in Chicago. At these places I have seen from 25 to 100 men, many of whom have national reputations, enjoying the splendid clinics and the gracious hospitality extended by the surgeons to visitors. The chiefs of these clinics realize what a compliment it is for men to come from all over the continent to learn from *hôpitaux*, which carries a formal request to the various directors of hospitals, etc., to assist the visitor with information and facilities; it also contains a list of all the hospitals under the jurisdiction of the Assistance Publique. In order to be admitted to the clinical lectures, ward visits and examination of patients, the physician has only to present his card to the concierge of the hospital and to ask by name for the physician or surgeon whom he wishes to see.

A physician who desires to take a practical course and to have the privilege of the library of the Faculté de médecine pays a matriculation fee of about $6 (30 francs), and in addition a fee for each practical course taken up, which is on the average about $10 (50 francs).

In various hospitals, clinics and laboratories there are *cours de perfectionnement* organized at various times of the year, especially during vacation. These are announced by placards posted in the buildings of the Faculté de médecine and the various hospitals and by notices in the medical journals. The newcomer is advised to consult the last few numbers of some such periodical as the *Bulletin médical* or the *Presse médicale* for notices of non-official courses (that is, those not given under the auspices of the Faculté de médecine).

The fees are variable, but rarely exceed $10 or $20. Moreover, there are several associations for complementary medical instruction which organize similar courses. Such courses are organized twice a year at No. 18 rue du Luxembourg, the winter series in November and December, the summer series in May and June. Vacation courses comprising the principal specialties are also organized in September and October. The price is about $4 (20 francs) a course.

The course in bacteriology at the Pasteur Institute is three or four months long, and therefore is not given more than twice a year. Names must be sent in to Dr. Roux or his assistants some time in advance.

A free information bureau for physicians and others, officially known as the Bureau de Renseignements Scientifiques, is maintained at the Sorbonne. It is open all the year around from 10 to 12 and from 2 to 5, with attendants able to speak German, English, Russian and Spanish, and catalogued information of all subjects of interest to persons intending to pursue scientific study.

"An English Handbook to the Paris Medical School," by A. A. Warden, published by P. Blakiston's Sons & Co., 1012 Walnut Street, Philadelphia, price 50 cents, contains a map of the Quartier Latin and much useful information in regard to the schools and courses.

The cost of living in Paris naturally varies according to the location and accommodations required. The physician who comes to Paris to study will find it to his advantage to live in the Latin Quarter, which is the seat of the Faculté de médecine and of the Collège de France and is in proximity to many important hospitals and clinics. Room and board in private families may be had for a price varying from $30 to $50 a month (150 to 250 francs). Room without board costs on the average from $10 to $12 a month.

BERLIN

Many American physicians go to Germany or Austria for postgraduate study. Especial advantages are found there for laboratory work and research, and instruction is said to be better organized, especially in Vienna The two most important centers of medical instruction in German-speaking countries, of course, are Berlin and Vienna.

Medical courses at Berlin are divided into: (1) the regular university courses, which are intended for the undergraduate students; (2) vacation courses given by the university instructors during March and October, and (3) monthly courses by private instructors, which are given the year around. These are mostly policlinic or dispensary courses and correspond closely to the instruction given in graduate schools in the United States.

Regular student courses at the University of Berlin are often designed more for undergraduate than for postgraduate work. An occasional visit to these courses is welcomed without formality. To attend regularly one must sometimes matriculate. The university work is divided into a winter and a summer semester, the winter semester lasting from October 15 to March 15 and the summer semester from April 15 to August 15. The time for matriculation is comprised in the two weeks preceding the opening of the semester and the first two weeks of the semester. The matriculation fee is 18 marks; diploma and passport must be shown. Vacation courses are given twice a year (March and October) during the university holidays. These courses are for graduates in medicine and can be very highly recommended. They are, however, sometimes overcrowded. Most of these courses begin on the first day or during the first week of the month and last for four weeks. Assistantships or so-called "voluntary" assistantships are often obtainable in out-patient departments and inside the hospitals. The requirements of such positions may best be obtained from the older men in the Anglo-American Medical Association or members of its orientation committee.

As mentioned in the Berlin Letter (THE JOURNAL, March 4, 1911, p. 682), a double fee for the summer semester of 1911 has been imposed on foreigners attending lectures or taking laboratory work. The increase amounts to 10 marks ($2.50) for students in medicine and the natural sciences.

The Anglo-American Medical Association of Berlin was formed to promote the interests of British and American physicians studying in that city. The headquarters of the association are at Friedrichstrasse 105b, where an information clerk is in attendance from 9 to 10 a. m. The president is Dr. Bruggemann, Berlin W., Barbarossa Str. 33. The membership fee is 10 marks (about $2.50) a year. The year-book of the association will be sent by the secretary, W. J. Griffin, on receipt of 5 cents in foreign exchange stamp coupons. It contains courses most frequently attended by Americans, but does not pretend to be a complete list of all courses given in Berlin.

For courses not announced therein the newcomer should not fail to consult the following publications: (1) Verzeichnis der Vorlesungen (list of university courses), price 60 pfgs; (2) Ferien-Kurse für praktische Aerzte (vacation list); (3) Schacht, Ratgeber und Wegweiser für Teilnehmer an ärztlichen Fortbildungskursen, price 1 mark; (4) Verzeichnis der Monatskurse, gratis; (5) Kurse für praktische Aerzte, gratis; (6) Verein für Aerzte-Kurse, gratis. Nos. 1 and 2 are the most important and will be sent to the United States on receipt of 25 cents in foreign exchange stamp coupons. They would probably be supplied either by the Anglo-American Medical Association or by the information bureau, similar to that mentioned at the Sorbonne, which is maintained at the Kaiserin Friedrich-Haus, Luisenplatz 2-4.

Postgraduate courses on a large variety of subjects are given under the auspices of the Bureau des Zentralkomitees für das ärztliche Fortbildungswesen in Preussen, Berlin N.-W. 6, Luisenplatz 2-4, Kaiserin Friedrich-Haus für das ärztliche Fortbildungswesen. The subjects offered include the following: pathologic anatomy, internal medicine, surgery, ophthalmology, the clinical and practical application of bacteriology, diseases of women, obstetrics, industrial hygiene, diseases of the nose and throat, urinary diseases and gonorrhea, dermatology and syphilis, diseases of children, including the nutrition of normal and diseased infants, clinical chemistry, care of the sick, gastric and intestinal diseases, diseases of the ear, surgical and mechanical orthopedics, the latest applications of water, light, heat and electricity to therapeutics, roentgenology, etc.

The recently opened Amerika-Institut, under the directorship of Prof. Hugo Münsterberg, in the Royal Library Building, Universitätstrasse 6, Berlin VII, seeks to assist Americans who wish to come into contact with German institutions, scholars, libraries, archives, laboratories, museums, hospitals, academies, etc.

It is imperative that American citizens bring with them passports. They must register in the consulate when arriving in Berlin. If possible it is best to reach Berlin about the twentieth of the month. According to information furnished by the Anglo-American Medical Association, at least one week should be spent in personal examination of the opportunities for study and in getting settled before beginning work.

DÜSSELDORF

The Academy for Practical Medicine, Düsseldorf, offers courses, open to foreign physicians, in pathologic anatomy and experimental therapy, and clinical courses in surgery, gynecology, obstetrics and pediatrics. The only expense is a registration fee of about $1.25.

VIENNA

Vienna presents many advantages from the medical student's point of view, one of which is the great amount and variety of the clinical material, since patients come to Vienna from territory within a very large radius. Another advantage is the centralization of facilities for instruction, which makes it possible for the student to economize his time.

There are ten large public hospitals, the chief of which, the Allgemeines Krankenhaus, comprises three clinics each of surgery and medicine, two clinics each for gynecology, dermatology and syphilis, ophthalmology, mental and nervous diseases, and one each for otology, rhino-laryngology and pediatrics. Some clinical teachers not only speak English fluently but give lectures in English in special classes. Within the last few years a magnificent new hospital has been erected a few hundred feet away from the old Allgemeines Krankenhaus, which is to be pulled down. It will contain only clinical wards for clinical teaching by ordinary professors. It is lavishly equipped in the most modern and scientific manner and will, when finished, contain 2,600 beds.

Besides this general hospital there are the Wiedner Hospital, the Rudolph Hospital and the Poliklinik, connected with the medical department of the university, in which clinical lectures are given also by professors during the semesters. The winter semester lasts from October till March 31, the summer semester from May 15 to July 15. The fees for clinical semester lectures are low, about $6 being the maximum, while special lectures are more expensive. A very good opportunity for anatomic and dissecting work is offered in the Anatomisches Institut, for pathologic anatomy and bacteriology in the Pathologisch-Anatomisches Institut. In these official institutes the fees for working and material come to something like $10 to $15 per term of eight weeks. There is also a well-equipped institute for the study of physiology, and one for histology of the nerves. A modern institute for experimental pathology and therapeutic research was opened two years ago. All the institutions mentioned above are in the same quarter or district of Vienna, called Alsergrund, and are conveniently near each other.

Those who wish to spend considerable time in the wards do not find it difficult to obtain the position of *Hospitant* in the wards, where they have the same rights as ordinary hospital officers, but not their duties; they, of course, receive no pay. The clinics for dermatology, practical medicine, syphilis, ophthalmology and otology especially are much frequented by American *Hospitants.*

The following are specimen charges in classes arranged by privat-docents and professors: Diagnostic classes for internal diseases, $10 for six weeks; hematology, $25, four to six weeks; surgery of the genito-urinary system, $20, four weeks; surgery of the ear, $15 to $20, six to eight weeks. In classes on rhinology the fees are between $20 and $40, including operations on patients. Surgical practice on the cadaver is obtainable as a special course. Urbantschitsch's classes on otology are much frequented by English-speaking physicians, and Finger's English classes on dermatology are an old-established institution. Furthermore, it is possible to get up a special class for nearly any branch of medicine if the lecturer is guaranteed a minimum fee varying between $100 and $150 for the whole class, so that there is a vast opportunity for both practical and theoretical teaching at a low cost to the individual members of the class.

The following is reported by an observer as a specimen day: From 8 to 10 a. m., class at von Noorden's clinic, a case of syringomyelia, two cases of multiple sclerosis; 10 a. m. to 12 m., Hochenegg's clinic, removal of a cancer of the breast, operation on a pancreatic cyst; 12 m. to 1 p. m., at Weichselbaum's pathologic theater, twenty-five fresh specimens, obtained during the morning at the necropsies, cancer of the penis, diphtheritic inflammation of the larynx, a volvulus, an anencephalus, a liver with fatty degeneration from phosphorus poisoning, typhoid intestines, leukemic bone-marrow, and several other interesting specimens; 1 to 2 p. m., a Cesarean section in Schauta's clinic; 4 to 5 p. m., a retinoscopy class in the second ophthalmic clinic, where cases of optic neuritis, iritis and keratitis specifica, glaucoma and a case of papilledema were shown; 5 to 6 p. m., work at a chemical laboratory; 6 to 7 p. m., an operative class on the ear of the cadaver.

There are two well-equipped public libraries. One is the large reading-room (Lesezimmer) of the Universitäts-Bibliothek, comprising about 400,000 books, and the other is the Aerztliches Lesezimmer in the hospital, with about 22,000 books and periodicals. English medical works are provided in abundance and access to these libraries is easily obtained.

The American Medical Association of Vienna, Schlösselgasse 28, Vienna VIII, secretary, Dr. M. W. Jacobs, also will be glad to assist any newcomer and to give information on study or other subjects.

A handbook in German, English and French of the postgraduate medical work under the patronage of the free organization for medical courses at the University of Vienna (Aerztliche Fortbildungskurse der freien Organisation für die medizinischen Kurse an der k.k. Universität Wien) is published by Urban & Schwarzenberg 1, Maximilianstrasse 4, Vienna, and supplied gratis on application.

A bureau of information for medical courses is maintained in the Allgemeines Krankenhaus, First Court, head offices (Direktion), first floor, room 14, where information can be obtained on personal or written application.

In the Alsergrund, the district which corresponds to the Latin Quarter in Paris, a conveniently situated room may be had for $8 or $12 a month. Board may be obtained for about $30 or $40 a month, or even less; $10 or $12 a week may be made to cover the expenses of decent living. There are low-priced private dining-halls for medical students and more expensive boarding-houses on the English plan. The following streets are suitable and convenient: Spitalgasse, Alserstrasse, Lazarethgasse, Pelikangasse, Kochgasse, Skodagasse, Schlösselgasse, Währingerstrasse and Garnisonsgasse.

TRAVEL NOTES OF INTEREST TO PROSPECTIVE STUDENTS ABROAD

The following letters and articles, published in The Journal and elsewhere, may be found of interest by the physician who is planning a trip abroad:

While the Continental Anglo-American Medical Society is not organized for purposes of instruction, the American physician traveling on the Continent may find it useful to have the list of its members, as it will give him the names of English-speaking confrères in continental Europe, and northern Africa as well. The honorary secretary and treasurer is Dr. Charles G. Jarvis, 81 Boulevard Malesherbes, Paris.

CONVERSATIONAL AIDS IN FOREIGN LANGUAGES

To the Editor:—Please give me information in regard to books that will aid practitioners in obtaining a working knowledge of German and French. L. R. C.

Answer.—One of the most rapid means of acquiring a foreign language is by reading articles in that language, comparing them meanwhile, sentence by sentence, with a literal translation. "Medical German," by Deutsch, price $1.75, contains conversations with patients in German and English. A volume of German-English medical dialogues, with dictionary and grammar, by Robert Lewin, is published by Dr. Werner Klinkhardt, Leipsic.

Other aids to conversations in French and German are P. Blaschke's English-German "Medizinisches Konversationsbuch," published by the Verlag von Walther Rothschild, Berlin. This is sold in this country for $1.20. Another work of this kind, "Englisch für Mediziner," about the same price, is published by the Verlag von J. A. Barth, Leipsic. But the most valuable work of the kind, perhaps, is the "Medical Vademecum in English and German" by B. Lewis, 1910, which is sold by P. Blakiston's Son & Co., 1012 Walnut Street, Philadelphia, for $5. This was reviewed recently in The Journal (July 30, 1910, page 425) and commended as an ideal means of obtaining a working knowledge of German without the necessity for a dictionary; the postgraduate lectures and talks are given in English and in German on opposite pages. Especial attention is given to the conversations needed in conducting the examination of a patient in various pathologic conditions. The sixty lectures are on various subjects and are authentic clinical lectures. "Self-Taught French" by F. Thimm, and similar pamphlets for German, Spanish and Italian, are published by Dick & Fitzgerald, 18 Ann Street, New York, and are useful for general conversation. A reply to a query in regard to dictionaries in foreign languages was published in The Journal, March 20, 1909, page 980.

The Public Service

Medical Department, U. S. Army

Changes for the week ended April 1, 1911.

Harmon, Daniel W., lieut., granted two months' leave of absence, to take effect on arrival in the United States.

Skelton, Robert, M.R.C., ordered to proceed to Fort Jay, N. Y.

Davidson, Wilson T., captain, relieved from further duty at Columbus Barracks, Ohio, and ordered to Fort McIntosh, Texas.

Davis, William R., captain, ordered to proceed from Fort Porter, N. Y., to Cleveland, Ohio, on official business pertaining to the medical department of the Army.

Heterick, Robert H., M.R.C., relieved from duty at the Army Medical School and ordered to Fort Brady, Mich., for duty.

Bundesen, H. N., M.R.C., resignation accepted by the President, to take effect March 30, 1911.

Williamson, L. P., lieut., ordered with Co. I, Signal Corps, from Nogales, Ariz., to Hachita, N. Mex., for station.

Wing, Franklin F., D.S., ordered to proceed from Fort D. A. Russell, Wyo., to Fort Robinson, Neb., for temporary duty.

Tuttle, George B., M.R.C., ordered to Fort Miley, Cal., for temporary duty.

Whitmore, E. R., major, on expiration of his present leave of absence ordered to Fort Barrancas, Fla., for duty.

Newton, R. W., M.R.C., ordered to proceed to San Antonio, Texas, and report to the commanding general, department of Texas, for temporary duty.

Blanchard, R. M., captain, left Fort Sheridan, Ill., to inspect the medical and hospital corps of the organized militia of the states of Ohio, Indiana, Illinois, Michigan and Wisconsin

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended March 29, 1911.

Stimpson, W. G., surgeon, granted seven days' leave of absence from March 25, 1911, under paragraph 189, Service Regulations.

McLaughlin, A. J., P. A. surgeon, directed to proceed to various places on the south shore of Lake Erie on special temporary duty.

Warren, B. S., P. A. surgeon, granted fifteen days' leave of absence from March 24, 1911, on account of sickness.

Stimson, A. M., P. A. surgeon, directed to proceed to Philadelphia on special temporary duty.

Pettyjohn, Joseph, P. A. surgeon, granted two months' leave of absence from March 23, 1911, on account of sickness.

Kearny, R. A., asst.-surgeon, directed to proceed to Astoria, Ore., and report to commanding officer of the Revenue Cutter *Manning* for duty.

Parcher, George, asst.-surgeon, directed to proceed to Ellis Island, N. Y., and report to the chief medical officer for duty.

Stiles, C. W., professor of zoology, directed to proceed to Wilmington, N. C., on special temporary duty.

Drs. George Parcher and Louis Schwartz, commissioned (recess) assistant surgeons in the Public Health and Marine-Hospital Service.

Boards of medical officers convened to meet on April 3, 1911, for the physical examination of candidates for appointment as cadet-engineer in the Revenue-Cutter Service. Stapleton, N. Y., detail amended *as follows: Passed Assistant Surgeon* W. A. Korn, chairman; Passed Assistant Surgeon E. A. Sweet, recorder.

Order convening board at Milwaukee, Wis., revoked.

Medical Economics

This Department Embodies the Subjects of Post-graduate Work, Contract Practice, Legislation, Medical Defense, and Other Medicolegal and Economic Questions of Interest to Physicians

FINANCIAL PROBLEMS *

Charles Haase, M.D.,

ELMIRA, N. Y.

COLLECTING ACCOUNTS

Laying aside all sentiment concerning the practice of medicine that has been handed down from the past when physicians made no charge but accepted honorariums, the fact remains that the physician, like the business man, must keep his income equal to or above his expenditures in order to maintain his credit. The business man from whom he buys expects to be paid; so why should not physicians also expect to be paid for their services? If a physician collects a good share of his accounts each year, it not only enables him to keep his family comfortable, but it also enables him to buy journals, books, instruments and other accessories, that make it possible to render better services to his patients.

Physicians should endeavor to collect from all who are able to pay, even invoking the aid of the law when necessary; but always remembering to take care of those who are unable to pay. It is better to do less business at a proper remuneration than twice the work at half pay. The income will be the same and there will be more time for study and recreation.

The physician's worst enemies are those who have old, unsettled accounts; and these enemies can be changed into friends if they can be made to settle their indebtedness. A person who owes the physician money and does not intend to pay will be one of the first to knock him.

"Short accounts make long friends." By accustoming all classes of patients to an early rendering of accounts, while the amount is small and the service is fresh in memory and appreciation, the satisfaction of both patient and physician will be better assured, collection facilitated, and a better financial morale promoted. The regular collection of accounts has several good effects on a doctor's patients; it teaches them that he expects to be paid for his services, it prevents the bill becoming so large that they are unable to pay it, it weeds out bad payers early, and it avoids many losses due to removals and deaths. To avoid payment people go elsewhere. A good rule to follow is never to allow an account to get larger than a family can comfortably afford to pay. It is unquestionably easier for patients to pay and for a physician to collect $10 twelve times a year than $125 once a year—or even $30 four times a year.

Soon after services are rendered a statement should be rendered, and on the first or fifteenth of each month thereafter. In long-continued cases, the physician should try to collect something while attending the patient. Some men never present a bill but wait the patient's pleasure to pay. This is demoralizing, as it puts the physician in a wrong light. The patient gets the idea that the physician does not need the money and can wait, and he is then often forgotten. Others present bills only once a year, which plan is also open to objection, for the patient accidentally or intentionally forgets the circumstances surrounding a case or the items of the account, and disputes the bill. After sending two or three statements and receiving no response, nothing gives such good results as personal visits.

The accounts may be given to an attorney or a local collector. It is important that a physician keep his word with his debtor. If the physician states that he will sue after a certain date, if the individual fails to make a satisfactory arrangement about his account, then he must do it. The moral effect of a successful collection is of more value than the costs. Having people say: "Dr. Blank is a good doctor, but he expects his pay," is worth hundreds of dollars and the reputation can be acquired by a couple of years of close collecting.

FEES

The income from a medical practice rarely equals the income obtained by men of equal ability, whose education and capital are invested in commercial pursuits, notwithstanding the great responsibilities physicians carry which laymen escape. The principal reason for this is that physicians have a constant tendency to settle down to a level—and that the lowest level of professional fees—from which they find it difficult to rise. There is too much tendency to dull routine in charges. There should exist a wide range of charges for medical services, depending on several factors, such as the severity of the case, time given to it, the dangers to the physician and his practice, and the ability of the patient to pay. People should be impressed with the fact that the fee bill represents the minimum fee for ordinary services only, and that when special attention is required a fee in accordance with it should be expected. This is done in surgical cases; why not in medical cases?

The price of a visit does not necessarily pay for services rendered. When, therefore, physicians try to collect something for extra services they are invariably confronted with the settled price of a visit. Such a procedure by no means compensates the physician under all circumstances. A rich man will have his life saved for a thousandth part of what he will pay a lawyer to save his business, and then he will object to the physician's bill. The lawyer long ago learned to value and to charge for special services according to their value and according to the ability of the client to pay; he no longer charges so much a visit or consultation.

When a physician has saved a patient from death or from poisoning he should charge for a major operation, which is what has really been performed, and he should not send a bill for $2 for a night call. It is the medical profession's duty to educate the unthinking public to appreciation of the fact that it takes more skill and a finer quality of judgment to carry a patient through a long period of critical expectancy terminating in a successful accouchement, than to amputate an arm or a leg, and that physicians should be paid accordingly.

In attending contagious diseases, physicians incur danger to themselves, their family and their practice. They should be compensated for the risk and the loss sustained, by a reward at least double that received in ordinary cases.

There is no need of rendering an itemized account to patients. In making out a bill, medical men should take into consideration time, ability and service; nothing less than this will insure the justice that they deserve. Unless physicians come to some understanding of this kind with themselves, unless they ask for a professional fee in proportion to their service and without fixed rates, they will never be paid for what they do. For example, during certain stages of a case of pneumonia or diphtheria, it is important that they be able to watch the case very closely and adapt treatment to the varying conditions, instead of making a regular visit and going back to the office to await further summons. If a lump charge be made, they will feel at liberty to call as often as necessary.

---

* Read at the Elmira Clinical Society, November, 1910.

The dead-level fee—the same price for everybody—for all kinds of cases—should have no place in medicine.

DISPENSING

It certainly pays to dispense: First, the patient has his treatment at once; second, he will return if he needs more medicine and the physician can see the effect of the medication and change, continue, or discontinue it as necessary; third, the patient cannot pass the prescription to his friends who are "just as he was." A physician who habitually writes prescriptions, or prescribes proprietary preparations, simply hands over to the public a part of his income. Hit or miss, the laity will essay to treat themselves and even their friends and neighbors by the name or number on the bottle or box. At times, when the physician has not the appropriate medicine, it will be necessary to write a prescription, but this will not happen often, if he learns thoroughly the action of the most important drugs and carries them in his case. Let physicians have printed on their prescription blanks, "Do not repeat" or "*Ne repetatur.*"

The New York Board of Health undertook to ascertain the extent to which substitution was being practiced in New York City, and sent out 373 prescriptions for phenacetin, with the result that only 58 were found to be pure phenacetin; in 315 there was substitution.

SUMMARY

To sum up: Let physicians collect while bills are small; educate the people that the fee schedule is only a minimum one; present bills in lump sums, and keep guard over prescriptions.

110 West Church Street.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
BOWLING GREEN, KENTUCKY

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Ninth Month—Second Weekly Meeting

ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM

WEIGHT and size of the brain and spinal cord in infancy and childhood. Rate of growth.

PHYSIOLOGY OF NERVOUS SYSTEM: Instability of nerve centers; excessive irritability of motor, sensory and vasomotor nerves; marked effect of reflex irritations; grave permanent effects following slight lesions.

DISEASES OF THE NERVOUS SYSTEM

CONVULSIONS: Etiology: Predisposing causes, instability of nerve centers, nutritive disturbances, constitutional diseases, heredity, etc. Exciting causes: (1) Direct irritation of cortex, meningitis, hemorrhage, abscess, etc.; (2) reflex irritation, digestive disturbances, injuries, phimosis, retention of urine, etc.; (3) toxic influences, uremia, asphyxia, acute infections, pertussis, convulsions associated with enlarged thymus. Idiopathic convulsions.

Diagnosis as to etiology.

Treatment in detail.

TETANY

ETIOLOGY: Age, sex, frequency. Rickets, gastro-intestinal disorders, bronchopneumonia, etc.

SYMPTOMS: Onset of spasm, extension, duration. Reflexes, effect of local irritation. Pain.

Diagnosis.

LARYNGISMUS STRIDULUS

Frequency, age, association with rickets. Symptoms and diagnosis.

REFERENCE BOOKS FOR THE NINTH MONTH

Holt: Diseases of Infancy and Childhood.
Koplik: Diseases of Infancy and Childhood.
Rotch: Pediatrics.
Starr: American Text-Book of Diseases of Children.
Taylor and Wells: Diseases of Children.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

DISTRICT OF COLUMBIA: Washington, April 11. Sec., Dr. George C. Ober, 125 B St., S.-E.

GEORGIA ECLECTIC: State Capitol, Atlanta, about April 20. Sec., Dr. C. W. Miller, 192 W. North Ave.

NEW MEXICO: Santa Fe, April 9-10. Sec., Dr. J. A. Massie.

OKLAHOMA: Oklahoma City, April 11. Sec., Dr. Frank P. Davis, Enid.

WEST VIRGINIA: Huntington, April 10-12. Sec., Dr. H. A. Barbee, Point Pleasant.

Colorado January Report

Dr. S. D. VanMeter, secretary of the Colorado State Board of Medical Examiners, reports the written and oral examination held at Denver, Jan. 3-7, 1911. The number of subjects examined in was 8; total number of questions asked, 80; percentage required to pass, 75. Nine candidates were examined, of whom 3 passed and 6 failed, including 1 osteopath. Twenty-nine candidates were registered on presentation of satisfactory credentials, including state licenses. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Denver and Gross College of Medicine,	(1910)	80.1, 80.1, 82.8

FAILED

College	Year Grad.	Per Cent.
Keokuk Medical College	(1898)	58

University of Nashville	(1899)	Nebraska

The following questions were asked:

ANATOMY

1. Describe the radius, including muscular and ligamentous attachments. 2. Describe the sternum, including muscular and ligamentous attachments. 3. Describe the elbow joint. 4. Describe the ankle joint. 5. Give the origin, insertion and nerve supply of the following muscles: triceps, pyriformis, peroneus longus, levator ani, levator anguli scapulæ. 6. Name the supinators of the forearm and give the nerve-supply of each. 7. Name the branches of the internal iliac artery. 8. Give the collateral circulation that would follow ligation of the common carotid. 9. Describe the lumbar plexus. 10. Describe the right kidney, including its relations. Alternate question: Where are the cortical centers of the face, arm and forearm?

PATHOLOGY

1. Give the pathology of acute anterior poliomyelitis. 2. Describe the process of amyloid degeneration. 3. Describe the structure of sarcoma, giving the various types. 4. How would you make a Widal test? 5. How would you distinguish *B. coli communis* from *B. typhosus?* 6. Define (1) anaphylaxis, (2) tuberculin, (3) *Treponema pallida*, (4) Wassermann reaction, (5) leukopenia. 7. Discuss

uremia. 8. Describe the most common tumor found in bone. 9. Describe the changes undergone in the brain after cerebral embolism. 10. Give microscopic appearances of a gumma.

PHYSIOLOGY

1. Discuss metabolism. 2. Discuss digestion. 3. Discuss elimination. 4. Discuss respiration. 5. Discuss circulation (blood and lymph). 6. Give a physical description of the blood, with functions of its component parts. 7. Define reflex arc, give examples of reflex action. 8. Give in outline the sympathetic nervous system with functions. 9. Give distribution and function of cranial nerves. 10. Define hyperopia, myopia and astigmia, giving general principles involved in their detection and correction.

CHEMISTRY

1. What is indican, and what does it signify when found in the urine? 2. How would you determine the presence or absence of acetone in urine? 3. Define osmosis. 4. What are the chemical constituents of normal urine? 5. Give a concise description of a chemical examination of normal urine. 6. Name a chemical incompatibility, describing the reaction. 7. What chemical tests are used in the detection of occult blood? 8. Give a general definition of an ether. 9. Give the composition of water by volume and by weight. 10. What is a compound radical? Give examples, with the valence of each.

TOXICOLOGY

1. From a medical standpoint define toxicology. 2. In the event you were called to a case with the following symptoms—drowsiness, headache, giddiness, stupor, delirium, convulsions and paralysis, what would be your diagnosis? 3. What would be your treatment? 4. Give symptoms of poisoning by lead acetate. 5. Treatment and post-mortem appearance. 6. Give symptoms of poisoning by tartar emetic. 7. Treatment and post-mortem appearance. 8. Give symptoms of poisoning by corrosive sublimate. 9. Treatment and post-mortem appearance. 10. Give difference in symptoms of poisoning by corrosive sublimate and those of arsenic.

SURGERY

1. Give the causes of arteritis and describe the symptoms and complications. 2. What are the symptoms and causes of lymphadenitis. 3. Give the symptoms of a tubercular abscess. 4. Discuss sarcoma of the kidney. 5. Give the symptoms and causes of acute osteomyelitis. 6. Give some of the complications and consequences of fractures. 7. Give the symptoms of fracture of the surgical neck of the humerus. 8. Give the symptoms of tubercular arthritis of the elbow joint. 9. Give the symptoms of dislocation of the head of the femur on the dorsum of the ilium and what per cent. of hip dislocations does this form comprise? 10. Give the symptoms of strangulated hernia.

OBSTETRICS

1. Describe in detail your procedure after arrival at the lying-in chamber when the patient is (a) in the first stage of labor, (b) in the second stage, (c) and the third stage. 2. Describe the toxemias of pregnancy and tell what you would do to prevent or relieve same. 3. What is "morning sickness?" Give causes, duration and treatment. 4. What are the indications for the use of the obstetrical forceps? Describe their application. 5. Give directions for the care of a woman after delivery—(a) normal, (b) instrumental. 6. When should a lacerated perineum be repaired, and give technic? 7. What means would you employ to prevent laceration of the perineum when the head is well down on the perineum and labor pains are strong? 8. How would you treat a case of ophthalmia neonatorum? 9. Give symptoms of pregnancy and their relative importance. 10. Give method of procedure in case of retained secundines in four month abortion.

SYMPTOMATOLOGY

1. Describe, locate and give causes of the different heart murmurs. 2. In what order and at what time do the teeth erupt in childhood? 3. Give symptoms of tuberculous hip-joint disease. 4. Give cause and symptoms of multiple neuritis. 5. Give symptoms of scurvy in children. 6. Give cause, prognosis and symptoms [illegible] Give symptoms of chronic appendicitis. 8. De- [illegible] in making a physical examination of the abdo- [illegible] between pyelitis and cystitis. 10. Give cause and symptoms of pulmonary edema.

Utah January Report

Dr. G. F. Harding, secretary of the Utah State Board of Medical Examiners, reports the written examination held at Salt Lake City, Jan. 4-5, 1911. The number of subjects examined in was 21; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 8, of whom 7 passed and 1 failed. One candidate was licensed through reciprocity. The following colleges were represented:

Book Notices

Dyke's Automobile Encyclopedia (1911). In 29 Parts, Including a Dictionary. Treating on Construction, Operation, Repairing of Automobiles and Gasoline Engines. By A. L. Dyke, E.E., Member Society Auto Engineers. Cloth. Pp. 407, with illustrations. St. Louis: A. L. Dyke.

It is not surprising that one edition of this book has been exhausted, for it is a most complete work. In twenty-nine instructions, or chapters, and with a profusion of illustrations, all well made and useful, the author endeavors to discuss the principles on which gasoline engines and automobiles are operated and built. He adheres strictly to the practical side of the subject, never indulging in theorization. The man who takes care of his own car will find this book full of useful hints and information. It propounds queries, such as are often put by a puzzled operator, and answers them. A separate chapter is devoted to "troubles."

Oxypathie. Von Dr. Wilhelm Stoeltzner, Direktor der Universitäts-Poliklinik für Kinderkrankheiten in Halle a. S. Paper. Price, 3 marks. Pp. 92. Berlin: S. Karger, Karlstrasse 15, 1911.

Stoeltzner proposes the term *Oxypathie* to cover all that is comprised in the French *arthritisme*, the English lithemia and the German *exudative Diathese*, and still further extends the ramifications of that very complex clinical picture. He finds these terms objectionable because they all unduly *emphasize one aspect* of the diathesis. The word *Oxypathie* conveys, furthermore, the idea that the essential condition in this diathesis is an acid intoxication of alimentary origin. Thus he maintains that the essential difficulty in feeding cow's milk to an infant lies in the absorption of phosphoric acid, a phosphoric acid intoxication, due to the liberation of a large amount of this acid from its normal combination with the large amount of calcium contained in cow's milk, because of the uniting of the large amount of fatty acids formed from the fat with this calcium. He believes a similar acid intoxication to be the basis of *Oxypathie* in general and finds the sovereign remedy in sodium citrate, which he considers almost a specific in infant-feeding with cow's milk, and even, under certain conditions, with breast-milk, in infantile atrophy, in infantile eczema (with almost unfailing results), in rickets, in scrofula, in asthmatic bronchitis, in lichen urticatus, cyclic vomiting, migraine, and also in the less definite manifestations, such as paleness, poor nutrition, nervousness, obesity, etc. Whether the reader will consider this new teaching as a stroke of synthetic genius, or as the elaboration of an idea dominated by an unconquerable bias, will make little difference in the enjoyment—and, we might say, profit—that he will obtain from a careful reading of the *ninety-two* pages of this rather startling little book.

The Prophylaxis and Treatment of Internal Diseases. Designed for the Use of Practitioners and of Advanced Students of Medicine. By F. Forchheimer, M.D., Professor of Medicine, Medical College of Ohio. Second Edition. *Cloth. Price, $5. Pp. 172.* New York: D. Appleton & Co., 1910.

This is a revision in fact and not merely a reprinting of the first edition. The aim has been to bring therapy up to date, to weed out obsolete and useless plans of treatment and to include whatever of the new appeals to the author because based on scientific principles, or endorsed by reliable men, or tried by himself and found acceptable. Several new chapters—some of them very short, we must admit—have been added, on such subjects as dysentery, Rocky Mountain fever, splenomegaly, tuberculous meningitis, etc. Serum therapy receives notice. Some chapters have been entirely *rewritten*. The sincere attempt to make a *practical*, scientific work on treatment seems successful. We *might occasionally* ask for a little more detail, as, for instance, how *to use the* quinin injections in amebic dysentery. Harm may perhaps come, it is said, from using too large an amount of water, *but we are not told* how much it is wise to *employ*; or whether in any case surgery is of avail.

Dead gonococci, the so-called vaccines, are mentioned as of service in gonorrheal arthritis. This is true, but their use is really limited to the chronic forms. Other articles are much fuller. We noticed particularly the discussion of diet in the treatment of obesity; also the treatment of chronic myocardial insufficiency.

The best feature of the book is that it contains the personal experience of the author; it is not a mere compilation from the literature. Every page bears the stamp of the practical physician who has tried nearly all of the plans of treatment recommended and knows whereof he speaks. The author's wide and varied experience, his sane judgment, and his ability to express his ideas clearly, forcibly and concisely, make the book a valuable addition to the library of the practitioner who is seeking aid in the treatment of internal diseases.

Medicolegal

Skill and Care Required in Making Tests to Ascertain Nature of and Treat Injuries—Error of Judgment

The Supreme Court of North Carolina considers test requirements in the malpractice case of Long vs. Austin (69 S. E. R. 500), where it affirms a judgment in favor of the plaintiff, who alleged that her shoulder joint had become dislocated by a fall, and that the defendant, on examination, failed to discover the dislocation and to apply such remedies as were necessary to restore the shoulder to its normal condition, which could have been done by the exercise of ordinary care and skill.

The court says that the mere use of approved tests, or those which have been found to be the best for the discovery of a dislocation or fracture or any other abnormal condition of the human body, is not all that is required of a surgeon or physician in the care and treatment of his patient. He must exercise that reasonable skill, care and proficiency in making the tests and in ascertaining from them the presence of any injury and generally in the treatment of his patient which a member of his profession of ordinary care and prudence should use under the circumstances. He is not bound or confined to any special treatment, but to an ordinarily careful and skilful one.

It was requested that the jury should be instructed that if they found that the defendant used the following tests: laying her right arm across her chest, placing her right hand on her left shoulder and pressing her right elbow against her chest, then placing her right hand on top or back of her head, and measuring both arms from the shoulder to the elbow and comparing the measurements, then the defendant would have used the proper tests, and if these tests failed to disclose the dislocation of the arm, then the jury should answer in the negative the question of whether the plaintiff was injured by the negligence or want of skill of the defendant, as alleged in the complaint. The court properly refused to adopt this language and to give the instruction as requested. The defendant's application of a test, even the ordinary and usual one, was not, by itself, a full compliance with the duty he owed to his patient. The requested instruction omitted any reference to the care and skill the law required him as a surgeon to bring to the use of the test and general treatment of the case. If he made the test and failed in other respects to exercise ordinary care, skill and diligence, he was just as liable for a consequent injury as if he had not applied the test at all.

The requested instruction was also deficient in not requiring the jury to find what was the proper test, especially as the evidence on this question was not all one way. A hypothetical question should contain all the facts essential to the expression of an intelligent opinion by the expert and of which there is evidence, and not a partial statement of the facts which could not present the entire matter to the witness, so as to enable him to give such an opinion as the law permits to be considered by the jury. The application of the ordinary test would be evidence on the question as to whether the defendant had exercised the care and skill required of him, but would not be plenary or conclusive proof or be fully determinative of the fact. He may not have applied the test properly, or, if he did, he may not have possessed the requisite knowledge and skill to understand the symptoms which it disclosed, or to apply the proper remedy. It was for the jury to decide, on the evidence and under the instructions of the court, whether the defendant possessed the requisite knowledge and skill and had carefully applied them in behalf of his patient.

Again, it was requested that the jury be instructed that if they found from the evidence that the defendant made a mistake or error of judgment only in his treatment of the plaintiff, they should answer "No" on the issue of whether the defendant was injured by the negligence or want of skill of the defendant, as alleged in the complaint. The instruction, as requested, was faulty in that it left out of consideration the material question as to the care and skill required of a physician when treating his patient. The jury were properly told that the defendant owed to the plaintiff that degree of care and skill which is ordinarily practiced and possessed by the average of his profession, and not the highest known to his profession. Where a physician exercises ordinary skill and diligence, he is not liable for a mere mistake of judgment. The law does not excuse an error of judgment if it occurs by reason of the surgeon's lack of that knowledge which he should possess in order to qualify him for the practice of his profession, or the failure to exercise the requisite skill and diligence.

Christian Science Healer a Practitioner of Medicine Amenable to Law

City Magistrate Freschi, of the City Magistrate's Court of the city of New York, First Division, Second District, holds, in People vs. Cole, on an application by the New York County Medical Society, that a warrant should be issued on an information charging the defendant, a Christian Science "healer," with practicing medicine without being duly qualified and licensed.

The magistrate says that he is of the opinion that the practice of the treatment of sickness and disease by inaudible prayer, as established by the evidence in this case, violates the law of New York State. The only theory on which the defendant could claim any right to practice as a "healer" of diseases and sickness was that the reservation, stated in the public health law of the state to the effect that it should not be construed to affect the practice of the religious tenets of any church, excluded him from the operation of the definition of the practice of medicine. It is, of course, true that the state constitution grants to every person freedom of conscience in matters of religion; but, on the other hand, it specifically provides that "the liberty of conscience hereby secured shall not be construed as to excuse acts of licentiousness or justify practices inconsistent with the peace or safety of this state." The public health and the treatment of diseases are matters of great concern to all states and the subject of proper public regulation in the exercise of their police powers.

From a study of a number of cases it must be ruled that religion is beyond judicial interference so long as one keeps it to himself and does not jeopardize others; but the moment there is an invasion of the rights of the state by some overt act or conduct that tends to affect the safety and future welfare of its people, then the civil government may intervene for its own protection and preservation. Religious belief is no excuse for an unlawful act. No person under the guise of the practice of the principles and tenets of any church may violate the law of the land. A thorough and prolonged search of all decisions in point rendered in the courts of our states fails to reveal that religion or its practice has even been construed to be a business.

The Christian Scientist has the right to believe that he can heal by prayers, but this court is of the opinion that if he carries and puts that belief into practice for hire and solicits patients by advertisement, then he exceeds his rights as an individual under the law and comes directly within the prohibition of the constitution. He must subordinate his beliefs to the rights of the community and of the state as an entity when the free exercise of such belief either impairs and endangers the health of the people or tends to place their health in jeopardy so that the safety of the state will be affected. Certainly the continuance of a practice or profession to heal as the defendant claimed could be done in this case ought to be the subject of judicial review of the higher and appellate courts.

Society Proceedings

COMING MEETINGS

American Medical Association, Los Angeles, June 27-30.

Alabama, Medical Society of the State of, Montgomery, April 18.
Am. Assn. of Pathologists and Bacteriologists, Chicago, April 14-15.
American Gastro-Enterological Assn., Philadelphia, April 19-20.
Am. Assn. Genito-Urinary Surgeons, New York, May 1-3.
American Dermatological Association, Boston, May 25-27.
American Gynecological Society, Atlantic City, May 23-25.
American Laryngological Association, Philadelphia, May 29-31.
American Neurological Association, Baltimore, May 11-13.
American Orthopedic Association, Cincinnati, May 15-17.
American Pediatric Society, Lake Mohonk, May 31-June 2.
American Society of Tropical Medicine, New Orleans, May 18-19.
American Therapeutic Society, Boston, May 11-13.
Arizona Medical Association, Bisbee, May 2-5.
Arkansas Medical Society, Fort Smith, May 2-5.
Association of American Physicians, Atlantic City, May 9-10.
California, Medical Society of State of, Santa Barbara, April 18.
Connecticut State Medical Society, Hartford, May 24-25.
District of Columbia, Medical Association of, Washington, April 25.
Florida Medical Association, Tallahassee, May 10.
Georgia, Medical Association of, Rome, April 19-21.
Illinois State Medical Society, Aurora, May 16-18.
Iowa State Medical Society, Des Moines, May 17-19.
Kansas Medical Society, Kansas City, May 3-5.
Louisiana State Medical Society, Shreveport, May 30-June 1.
Maryland, Med. and Chirurgical Faculty of, Baltimore, April 25-27.
Mississippi State Medical Association, Jackson, April 11.
Missouri State Medical Association, Jefferson City, May 16-18.
Montana State Medical Association, Butte, May 10-11.
Nebraska State Medical Association, Omaha, May 2.
New Hampshire Medical Society, Concord, May 11-12.
New York, Medical Society of the State of, Albany, April 18.

Washington State Medical Association, Spokane, May 9-11.

TRI-STATE MEDICAL ASSOCIATION OF THE CAROLINAS AND VIRGINIA

Thirteenth Annual Session, held at Raleigh, N. C., Feb. 22-23, 1911

Officers Elected

The following officers were elected for the ensuing year: President, Dr. J. Howell Way, Waynesville, N. C.; vice-presidents: for North Carolina, Dr. Thomas E. Anderson, Statesville; for South Carolina, Dr. F. H. McLeod, Florence; for Virginia, Dr. W. E. Anderson, Farmville; secretary-treasurer, Dr. Rolfe E. Hughes, Laurens, S. C.; councillors: Drs. E. C. Register, Charlotte, N. C., W. W. Fennell, Rock Hill, S. C., Samuel Lile, Lynchburg, Va.

The next meeting will be held in Columbia, S. C., the third Wednesday in February, 1912.

The Hon. W. W. Kitchin, Governor of North Carolina, delivered the address of welcome.

President's Address: Preventive Medicine

Dr. Joseph White, Richmond, Va., delivered his address at a special evening session, and it was unanimously voted by the association that the address should be published, not only in the medical journals of the three states, but in some lay monthly magazine of large circulation in the South. He said in part:

The work of Pasteur, Koch, Ross and others in the last century has made possible such triumphs of modern medicine as the construction of the Panama Canal, the suppression of yellow fever in Cuba, the reduction of the death-rate from tuberculosis, the control of bubonic plague, the elimination of typhus fever, the prevention of rabies and the cure of syphilis. Preventive medicine has almost eliminated puerperal infection; has furnished specific treatment for diphtheria and cerebrospinal meningitis, and is waging a strong battle against ophthalmia neonatorum. Why should Virginia and the Carolinas be so far behind in the matter of registration of midwives? In some of our sister states this matter has been properly regulated. The medical inspection of school children and school hygiene are now recognized as the best means a state can adopt to insure good citizens in the future. The removal of tonsils and adenoids, the correction of defective vision and hearing, and the removal to outdoor schools of the tuberculous children in our schools is economy of the best sort and should be a matter of public concern.

Report on Some Patients Treated With Salvarsan

Dr. Lawrence Price, Richmond, Va.: The method of preparation of the drug for administration was an adaptation of two of Ehrlich's methods combined with that of Junkerman. In five cases I used methyl-alcohol to dissolve the salvarsan. In all of the patients the drug was injected hypodermatically into the gluteal muscles. With four no alcohol was used, the drug being dissolved with warm sterile water. The administration in one case was subcutaneous; in three, intravenous. From experience with four out of nine cases, I concluded that the Wassermann reaction does not become negative under fourteen days, when the intramuscular method is used. I have not been able to notice any difference in the rapidity of the disappearance of lesions by one method over the other, though mucous patches clear up more rapidly than skin lesions. In all of the first eight cases I am administering by mouth mercurial treatment, and intend to continue so, regardless of the finding by the Wassermann test, for a period of five or six months. The method of administration, I think, should be governed by the stage and extent of the lesions, though from the patient's standpoint, the intravenous method is more desirable because of the absence of pain afterward; but the technic of administration by this method is rather dangerous, unless extreme care is exercised to avoid getting air into the vein; and, also, care that everything used from the beginning of the preparation of the dose to the dressing of the wound should be absolutely sterile, together with close attention to the technic of intravenous injection. I believe that the desired results can be obtained by the intravenous method if salvarsan be administered during the primary and very early part of the secondary stage, before any pathologic changes have taken place in the various tissues of the body, because of the floating action of the drug when thrown directly into the circulation. In the late secondary and in the tertiary stages, a more gradual and continuous action on the spirochetes is desired, so I advise the intramuscular method. In one case reported there were untoward effects which I believe were due to overdosing with chloral; in two others, the pain down the thighs and legs did not clear up entirely for two weeks. The curative effects of salvarsan in the treatment of syphilis during any of its stages is, in my opinion, unquestionably proved, if the drug is properly prepared for administration. I believe that many of the reported untoward effects and recurrences have been due to improper dispensing.

DISCUSSION

Dr. Tom A. Williams, Washington, D. C.: The fact that we should diagnose tabes without a reaction is clear, and is illustrated by a case which I saw last autumn. There was a persistent negative Wassermann reaction, but the character of the distribution of a pain in the line of the distribution of the fifth lumbar root was so characteristic that in spite of bladder symptoms having been cleared up by proper treatment, I injected mercury and the pain cleared up in a few weeks. However, the man relapsed again in five weeks and showed positive reaction. I gave salvarsan intravenously; but the pain disappeared for only one week, the reaction becoming negative completely for one week only; the man is now taking mercury. It is a question if we should administer this drug in preference to mercury, which, properly used, can arrest lues, and even parasyphilis, as the cases of Dana and myself indicate in this country, following those of Babinski and his followers in France.

Diagnosis and Treatment of Tumors of the Breast

Dr. J. Shelton Horsley, Richmond, Va.: Knowledge of practical pathology is a necessity to any surgeon who operates on tumors of the breast. In many instances the diagnosis must be made at the operating table, as no tumor should be cut into for diagnostic purposes unless operation follows immediately. The surgeon should carry the pathology in his head and fingers and not in those of some one else. I follow the classification of Warren, dividing tumors into cancer and fibro-epithelial tumors. The latter class is subdivided into those in which the fibrous tissue predominates and those in which the epithelial tissue is most prominent. The last-mentioned tumors are likely to degenerate into cancer and usually occur late in life. I wish to emphasize two points in making the diagnosis of cancer: first, the detection of the slightest tendency to retraction; and, second, the absence of pain. The first symptom may be tested by moving the skin over the tumor, by moving the tumor within the breast substance and by moving the breast on the fascia of the pectoral muscles. The slightest limitation of motion is exceedingly suggestive of cancer. The patient should be stripped to the waist and sitting on a stool in a good light; if the shoulders are equal the nipple of the affected breast will be at a little higher level than the nipple of the healthy breast if the tumor is cancerous. If the tumor is a benign one, the nipple will be either lower or on a level with the nipple of the healthy breast. This is due to the fact that cancer cells form some product that is irritating to the tissue and tends to cause contraction, just as contraction in cirrhosis of the liver is caused by irritation. In the majority of cases a correct diagnosis can be made in the early stage by the ordinary signs and symptoms without resort to incision; but the diagnosis should always be cleared up at once whenever a patient presents herself with a growth in the breast, as the chances for permanent cure in cancer of the breast mathematically decrease with each day of delay. I have never known of pain in any cancer of the breast in the early stage, though the laity and some physicians seem to think this a constant symptom. Pain is more likely to be present in a benign tumor than in a cancer, though it is not often encountered with in any tumor of the breast in the early stages. If incision is necessary for clearing up the diagnosis, the patient should be prepared for immediate operation, either radical or local, depending on the diagnosis that the incision will show. There is practically no danger in following an incision immediately by operation, but to incise a cancerous growth and operate a day or two later invariably results in recurrence. If the growth incised is a benign tumor, it will bulge into the wound and its capsule will retract. If it is cancerous, there will be no distinct capsule and the growth will lie flat as though the incision had been made into a piece of wax. If the growth is cystic and is cancerous, its contents will be either dark and grumous or bloody and the wall of the cyst will be thickened throughout or in patches. If the cyst is benign the wall is thin and its contents will be either clear or straw-colored. I advise local extirpation in benign tumors and radical operation in cancer, beginning at the axilla and excising all of the material with a wide margin of skin in one mass.

DISCUSSION

DR. J. T. BURRUS, High Point, N. C.: I am much interested in cancer, and spent the greater part of last year in a cancer hospital. I am convinced that to lower the mortality from cancer in this country we must make an early diagnosis and then do a sufficiently radical operation. There is nothing closer to criminality than to go into cancer substance. I remember a case of a melanotic sarcoma in which the surgeon had gone into the cancer substance, and in less than six weeks metastasis had developed in the supraclavicular glands and the glands of the neck, on both sides.

DR. J. W. LONG, Greensboro, N. C.: One phase of this subject which I think should not go unnoticed is the contagiousness of cancer. Just one illustration: It had been noticed that the fish in certain pools in the State of New York were subject to cancer of the thyroid gland, and this was observed so constantly that, in order to test the matter, young puppies were brought from another section of the state and allowed to drink water only from one of these pools that contained cancerous fish. In a short time every one of the puppies developed carcinoma of the thyroid.

DR. G. P. LAROQUE, Richmond, Va.: The best way to cure cancer is to prevent it, but if it has already developed we should remove it at the earliest possible moment. Therefore, every tumor of the breast, even when not obviously cancer, should be removed at once and subjected to microscopic examination by a competent pathologist. It seems to me a little illogical to make a diagnosis by the absence of anything, and [illegible]lly by the absence of pain. A tumor which is actually [illegible] If not painful may be complicated by traumatism or [illegible]tion and become the seat of pain, even though cancer is not painful. As a matter of fact, a large number of cancers of the breast are secondary to mastitis and mastitis is necessarily painful.

The Cancer Committee

The association, through this committee, is waging active warfare against cancer in an effort to lessen materially the 80,000 deaths from this cause in the United States each year.

The present committee was unanimously continued for another year. This committee will be divided into sub-committees, with Dr. Horsley of Virginia, Dr. Rankin of North Carolina, and Dr. Williams of South Carolina, as chairmen, and the members will meet within these three states several times each year. They will prepare circulars and distribute them as widely as possible, the council being requested to furnish funds for this purpose. The boards of health have promised their cooperation, and each member of the association has been urged to do his part toward educating the public in the prevention of this disease. In addition, literature on the subject is to be sent to the members of the association, fully disclosing the plans and purposes of the committee, and the lines on which they will be asked to cooperate in educating the laity.

The Conservation of Sight

DR. J. W. JERVEY, Greenville, S. C.: The preservation of the public sight must be a great factor in the development of a people. Sins are daily being committed by a modern civilized people on a nation's eye-sight; but all the errors are preventable and many of them easily so.

The factors injuring vision are as follows: Ophthalmia neonatorum; pernicious activity of the so-called optometrists; the advertising eye doctor; the white incandescent mantle and electric bulb; badly printed newspapers and school books; badly lighted schools; unsuitable school desks; kindergartens; moving-picture shows; antipathy to the use of glasses.

DISCUSSION

DR. ROLFE E. HUGHES, Laurens, S. C.: I desire to emphasize especially one point: the prevention of ophthalmia neonatorum. I wonder why more obstetricians do not make it a rule to use a prophylactic remedy of from 1 to 2 per cent. silver nitrate. I have for years done that as often as I ligate the umbilical cord. And I might add, in the case of the male, a circumcision would be another good step at this time.

At the conclusion of Dr. Jervey's paper a motion was made, and unanimously seconded, that the Tri-State Medical Association request that Dr. Jervey's paper be published in one of the leading national weekly or monthly lay magazines as a contribution from the association to the education of the people. The motion was adopted.

Rheumatism

DR. J. N. UPSHUR, Richmond, Va., discussed the causation of rheumatism, his deductions from reports of investigations to the present day being that the causation of rheumatism from a germ has not yet been satisfactorily established, and clinical observation shows that the best results come from treatment on the old theory of unbalanced metabolism. He emphasized the use of alkalies, notably, bicarbonate of potash, until the secretions become neutral; following this up by the administration of some one of the salicylates, the best results are obtained, with much diminished risk of heart involvement. He recommended ammonium carbonate, in doses of from 5 to 10 grains every two hours, as a most satisfactory remedy in the treatment of endocarditis, minimizing the risk of emboli, and subsequent damage to the heart valves.

DISCUSSION

DR. J. N. WALTON, Richmond, Va.: It was shown more than thirty years ago that the combined Fuller, or alkaline treatment, with the salicylates would reduce the heart complications to the minimum. Bicarbonate of potassium or sodium, well diluted in water, should be given frequently enough to keep the urine alkaline; the nurse should be supplied with litmus paper and the urine should be tested for acidity several times a day. The salicylates are liable to ruin the digestion and the least objectionable is the effervescing salicylate of strontium to be given well diluted in cold water. In chronic rheumatism the treatment should be dietetic and eliminating, and experience has abundantly established the value of hydrotherapy and electricity over all other agents in the successful treatment of this type of rheumatism.

DR. DOUGLAS VANDERHOOF, Richmond, Va.: In this connection I would call attention to a paper published several years ago by Dr. T. W. Clarke, of the Lakeside Hospital, Cleveland, Ohio, in which he advocated the use of large doses of sodium salicylate at the onset of acute arthritis. He gives 30 grains of sodium salicylate every four hours for eight doses—half an ounce of the drug in thirty-two hours. In acute rheumatic fever this treatment promptly relieves pain, and also reduces the fever and the swelling of the joints, whereas in acute gonorrheal arthritis the symptoms are not so marvelously alleviated. In a rather large series of cases of acute rheumatic fever, these massive doses were found to be not injurious to the heart but rather served to protect that organ by cutting short the course of the disease. In my hospital experience I had good opportunity to prove the value of this procedure in the differential diagnosis of certain cases of acute arthritis.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES

Annual Meeting, held in Chicago, Feb. 27-28, 1911

(Concluded from page 997)

Report of Judicial Council

The judicial council reported favorably on the applications for membership of the Medical Department of the University of Minnesota, Northwestern University Medical School, and the Medical Department of Syracuse University.

A number of recommendations made in this report were acted on in general meeting, and have appeared elsewhere.

Report of Committee on Medical Education

After considering the question of a five years' course, the committee did not deem it wise to present a schedule for consideration at this time. The present unsettled condition of medical legislation in the states of the Union, coupled with the uncertainties that exist among the colleges, has left the subject in a state of uncertainty which precludes the presentation of any schedule. The questions that confronted the committee were: 1. Shall the fifth year be a terminal one to the present four years' course and limited to clinical training, or shall a part of the time be given to the study of medical sciences in the beginning of the course? 2. In the states where legislative enactments have advanced the requirements beyond a high-school standard, no provision has been made as to whether the course shall be given absolutely in a literary college or as a preliminary course in a medical college. The trend of legislation, however, has been toward the literary training rather than increasing the medical curriculum. The difficulties in the way are that very few of the literary colleges are equipped to give a definite premedical course, and very few are willing to change their present curriculum to accommodate the medical colleges. The committee did not deem it wise for the association to adopt any prescribed schedule for a five years' course, but believes that the colleges in membership in the association should urge on their graduates the necessity for a hospital year before entering practice, and that proper inducements should be offered them to take the course.

With regard to the concentration method of teaching, no definite conclusions were given. Many colleges have already adopted the method in part, but none are ready to recommend or reject the system. At the suggestion of the committee, the matter was laid over for one year. The following resolutions were presented by the committee and adopted.

WHEREAS, The time devoted to the study of pharmacology, materia medica and therapeutics is necessarily limited, and

WHEREAS, The thorough knowledge of a small but representative group of medicaments is conducive to scientific progress in therapeutics; therefore, be it

Resolved, That the Association of American Medical Colleges commends to the attention of medical educators and examiners the limited materia medica lists published by the joint committee of the Council on Medical Education, and of the National Confederation of State Medical Examining and Licensing Boards, and the Chicago Medical Society.

Resolved, That the association urge on the colleges and the examining boards the necessity for the recognition of the principle underlying these lists, and for the early adoption by the boards of a materia medica list to which licensure examinations shall largely be confined.

The committee approved of and commended the suggestion made by the president in his address that wider cooperation of the members in the work of the association would be of benefit, and, further, that the president be authorized to appoint a representative from the association to attend all the conferences, public and private, of the Council on Medical Education.

The Fifth Year in Medicine: The Hospital Year

DR. F. F. WESBROOK, Minneapolis: In presenting the plan which has been adopted in Minnesota for a fifth or hospital year, it is apparent that the viewpoint is not simply that of the welfare of the medical college but that of the good of the people of the state. It is recognized that what may be advantageous for a state situated as is Minnesota may be quite unsuitable or impracticable for other states where conditions are radically different. In order to secure the opinion of those in Minnesota who are specially interested, written information as to the desirability of a fifth or hospital year was obtained from representatives of various hospitals, of the medical press, from influential members and officers of the Minnesota State Medical Society, members of the Minnesota State Board of Health, of the Minnesota State Board of Medical Examiners, medical officers of state institutions and other similar sources. The requirement was announced last year and goes into effect with the class entering college in September, 1911, which means that compulsory internships must be provided in 1915. This affords four years' time for the final perfection and announcement of methods. A committee of the faculty of the College of Medicine and Surgery has been appointed to perfect final arrangements. Since this committee has not yet reported, it is impossible at this time to give the details of the plan as it will be put into operation.

At present 90 per cent. of the students voluntarily take internships, so that the carrying into effect of the announced plan will mean simply the requirement of one more year of service for a few students. To make these requirements compulsory for all will, however, protect the state in a number of directions. The plan provides a further year of collegiate supervision for students before they are granted degrees. It protects the college and the state against the granting of degrees to those who may be satisfactory students but who may prove to be unfit, incompetent or unpractical in the care of patients. For the hospitals, advantage is secured in providing a stimulus to better work and sustained service on the part of interns, since the degree will be withheld unless the hospital service of the student is satisfactory to the proper authorities. For the successful carrying out of the work, the state university must establish a set of requirements as to the size and scope of hospitals, methods of organization, facilities for scientific work and case records, and such other details as may prove necessary to standardize the hospitals for the purposes of this fifth or clinical year of medical education. It is believed that hospitals so standardized will welcome affiliation with the university. The further opportunities it provides for medical and public health cooperation in the state and in furnishing an added stimulus for each hospital to become a scientific center for the physicians of the locality are apparent. The available internships in Minnesota will far outnumber the local candidates for the positions. The university hospitals, when completed, will provide a large share of the required positions. The Minnesota State Board of Medical Examiners, according to the law, does not require graduation but demands of its candidates for licensure four years of work in a recognized medical college and two years of premedical college or university work, which is equivalent to that provided by the University of Minnesota. These equivalents are determined for the Minnesota State Board of Medical Examiners, as in the case of students entering the College of Medicine and Surgery, by the Registrar of the University, or when necessary, by the Enrolment Committee of the College of Science, Literature and the Arts of the University of Minnesota. Whether the future graduates of the College of Medicine and

Surgery shall be required to take their examinations for license to practice medicine at the end of the fourth year or college course or at the end of the fifth year or hospital service has not been determined. Nor has it been decided whether it is desirable to substitute graduate research work for the hospital year in the case of those who wish to qualify, not for medical practice, but for teaching and research posts. It has seemed to the people of Minnesota that owing to the increase in present-day knowledge in chemistry, physics and biology, and in their increased applicability to the diagnosis, prevention and cure of disease, nothing less than seven years of university and clinical work should be demanded of candidates for a medical degree after graduation from an accredited high school.

DISCUSSION

Dr. John M. Dodson, Chicago: In schools which have the college requirement for admission, the time is ripe for the addition of the hospital year. Rush Medical College has had an optional fifth year for some time, but cannot make it compulsory because in Illinois a degree is necessary for licensure and the student must have a license in order to become an intern. The difficulty, however, is not in finding openings for the students, but to find students enough to fill the places. The chief difficulty would be on the side of the hospital, though this educational movement would be as good for the hospitals as for the students. Many hospitals are not adequately equipped and are not careful enough about having the work done properly. Interns are burdened with routine work and are obliged to look after too many patients. No intern should have more than twenty-five or thirty beds under his direction at one time, in order to make a proper study of his patients. In the University of Chicago, the intern is under the personal charge of some member of the faculty, who investigates the hospital and keeps in touch with the intern's work. The intern is also required to do some original work and present a thesis, which I regard as a most important thing, during his hospital year.

Dr. F. C. Waite, Western Reserve University: In Cleveland, we are able to place every man in a hospital, but we find that there are different grades of men as there are different grades of hospitals, and we propose to allow them to distinguish themselves in a way. The student will do a certain amount of work on which he is to report, and he must do something in the way of original work. When that is creditably done, he is to get an additional degree—Master of Medicine. His special work need not necessarily be medical, but may be laboratory or anything pertaining to his medical education. In this way we hope to induce men to go into hospitals.

Dr. H. A. Christian, Harvard University: It is desirable that every man who is to practice medicine should have practical experience in a hospital. Conditions in the east are not as they are in Minnesota. I would favor the plan outlined by Drs. Dodson and Waite. Unfortunately, the colleges of to-day are not in the position to assume the burden of a fifth year, and many schools would have difficulty in placing their students in hospitals because they do not control sufficient hospital positions. It would be well to await the outcome of the trial which is to be made by the University of Minnesota. The college may require five years, or it may furnish an incentive by offering an honorary degree for good work or make a practical degree necessary for licensure. That would give the student freedom in selecting his hospital. Many men go into laboratory work who would not be particularly benefited by hospital training, and yet the practical experience of hospital service is not to be undervalued. It seems desirable to require such a training of every man going into the practice of medicine, but not of the man preparing for work other than general practice. At the same time, I would favor the demand on the part of the licensing board of a practical hospital experience.

Dr. Egbert LeFevre, University and Bellevue Hospital Medical College: Everyone appreciates the need for the year of hospital work. In many localities it can only be postgraduate, as yet, and we can only recommend it as such. I am not in favor of having it made obligatory in the present state of control of hospitals. Hospitals are unwilling to consider themselves as adjuncts to the medical college, and until we have educated the hospital boards to the desirability of this close connection, we cannot require a fifth year.

What the Internist Wants the Anatomist and Physiologist to Teach

Dr. Benson A. Cohoe, University of Pittsburg: The business of the medical school is to produce physicians who can heal the sick; the teachers of anatomy and physiology may direct their teaching toward practical ends or they may treat their subjects in a broadly scientific manner. An attempt has been made on the part of some medical schools to bridge over the more or less real gap that exists between the teaching of anatomy and physiology as pure science or in practical application to the clinical branches. Courses in topographic, applied, surgical and medical anatomy are offered by many schools, either as elective or as required subjects. Only two schools offer a special course in medical anatomy; one school offers a course in applied physiology; seven give courses in pathologic physiology; one school gives a course in medical technics. Clinicians desire that both anatomy and physiology be taught in a broadly scientific manner. The teaching of isolated facts of so-called practical value, at the sacrifice of fundamentals, would be a grave error. The most fitting place for the student to acquire a knowledge of anatomy for practice is in the dissecting room. The special course in medical anatomy, distinct from surgical anatomy, can be made of considerable aid, and should be taken up by the instructor in physical diagnosis. In such a course the living model should be employed.

To urge a greater practical application of physical facts is, under present conditions of physiologic knowledge and teaching, entirely unnecessary. A wise plan adopted in a few schools is to allow the student to choose some special field for exhaustive experimental work with the aim of teaching him thoroughness and initiative in his methods of work as a student and methods of precision in the study of his cases as a physician. The consensus of opinion is that that student is best prepared for the practice of internal medicine who has been trained in a school where these primary branches are taught as pure sciences, and where, not unmindful of their practical application, the imparting of the fundamental principles of these sciences is regarded as paramount, and in which no attempt is made at a short cut to the goal of medical learning by keeping practical facts ever in the foreground at the expense of pure science.

What the Surgeon Wants the Anatomist and Physiologist to Teach

Dr. C. B. G. de Nancrede, University of Michigan: Those teaching in schools where the scientific side of the subjects under consideration are largely ignored in favor of the so-called practical aspects overlook or underestimate the fact that where the scientific side is not neglected better results are obtained. Yet it cannot be denied that there is room for improvement in securing the knowledge of anatomy and physiology which the surgeon needs. The advantages of the old system of acquiring anatomic and physiologic knowledge must not be overlooked. I would earnestly protest against curtailing the scope of instruction on these important subjects. It is not the fault of too much science, but too little, or at least the proper proportion at the proper time, and no amount of so-called teaching of practical anatomy will give the student such a spirit of catholic knowledge and interest in anatomy as a proper combination of the scientific with the miscalled practical. The surgeon wants anatomy taught with as broad a scientific foundation as feasible, supplemented by such a sharp presentation of the facts of general anatomy as will show what structures must be injured during any operation in a given region, what may be injured or destroyed, and what must not be injured, much less sacrificed. Would it not be possible to hold over the student's head the certainty that the internist and externist will hold an examination, the one on physiology, the other on anatomy, as part of the final examinations for a degree? In this way the advantages of the old and new methods would be combined. A proper knowledge of scientific as well as so-called surgical anatomy is of equal importance in the diagnosis of surgical conditions as in their treatment. The same is true of physiology. The surgeon needs these aids, while the teacher cannot successfully instruct when students do not possess them.

DISCUSSION

Dr. E. P. Lyon, St. Louis University: Anatomy and physiology should be taught from the scientific standpoint and not merely to point out the features thought to be of practical value. I believe that there should be in the medical school a man who has not the M.D. degree, but who is really well versed in one of these sciences. We need the trained anatomist rather than the physician who can teach anatomy.

Dr. H. A. Christian, Harvard University: We have too many separate courses in our curriculum to-day. It seems to me that it is not desirable to have separate practical courses in anatomy or physiology. The anatomist and physiologist must give his time to teaching the fundamental principles. The internist and surgeon must teach these subjects as applied sciences.

Dr. B. D. Myers, University of Indiana: It seems to me that applied anatomy is a very necessary part of the medical course. The student should have it as a foundation for physiology, medicine and surgery, and therefore it should be taught in the beginning of the course.

Dr. J. S. Ferguson, Cornell University: The anatomy from the side of the internist demands not so much the knowledge of the dissecting room as it does an accurate knowledge of the conditions in which the tissue exists in the body as shown first by the gross appearance; second, by its macroscopic structure, and, third, the application of the whole structure to the function of the organ.

6. **Injection of Salvarsan into Lumbar Muscles.**—On the basis of experimental observations, Meltzer offers: first, the suggestion in a general way, that in medical practice injections of drugs should be made into the lumbar muscles, especially in cases in which a rapid effective action is urgently needed. Second, he states specifically that salvarsan should be injected into the sacrospinal muscle. This muscle presents anatomically an exceptionally well-isolated, large, compact mass, densely packed with fine muscle bundles. Any solution or suspension injected strictly into this mass will remain there and not affect locally the adjacent tissues. Experimentally, Meltzer found that the absorption from this muscle is superior to that from the gluteal muscles and vastly superior to that from the subcutaneous tissue. Clinically, it was established in a limited number of cases of syphilis that salvarsan injected into this muscle exerts a fairly rapid, unmistakably beneficial influence on secondary and tertiary manifestations of syphilis and on the Wassermann reaction without causing pain and other ill effects deserving any serious considerations.

11. **Bilateral Fibromyoma of the Broad Ligament.**—The case reported by Eising is unique inasmuch as it is bilateral, and the masses were not cystic. Owing to the intimacy between the tumors and the body of the uterus, a hysterectomy was done, removing simultaneously the intraligamentous tumors. The patient made an uneventful recovery. The microscopic examination of the tumor showed it to be a fibromyoma. The dimensions of the entire mass including the uterus were: Laterally, 7¼ inches; vertically, 4½ inches; anteroposteriorly, 3¾ inches.

12. **Diagnostic Value of Tuberculin.**—Of 135 cases in which the eye test was made by Mills, nineteen came to the post-mortem room. There were ten cases of advanced disease. Of these, four cases can be considered. One gave absolutely no reaction, two gave only slight reactions, and the fourth gave a negative reaction on the first trial, a positive on the second, but this was in the same eye and is without value. The patients all died within a comparatively short time (from three days to thirty-five days), and the results correspond with the results of others and with those of the injection method, that is, in advanced or very active cases, especially just before death, the reaction is absent or slight. The other six cases were positive; all but one patient lived a considerable time beyond the test, and the disease was not in so active or advanced a stage at the time of test as in the four above described. In the one exception, the primary cause was Addison's disease. The next group included cases with scars and evidences of former tuberculosis, nothing of an active nature being present at death. In this group there were seven cases. Three of these were negative; one gave only a questionable reaction at the end of sixty hours, and three gave positive reactions. This proves conclusively, Mills says, that old, healed lesions can give positive reactions, and strongly positive ones, but at the same time shows that a negative reaction does not exclude an old lesion. The third group includes two cases with negative autopsy findings, and both gave negative reactions. Mills has found that from 20 to 25 per cent. of insane patients will react to the ophthalmo-tuberculin test, in whom no demonstrable lesions can be found, but it is probable that in all of them an old focus will be found post mortem. Therefore, a positive reaction in the absence of clinical signs is of no significance, but a negative reaction, except in advanced or very active cases, positively excludes tuberculosis. Mills regards the test as being as reliable as any other tuberculin test, more reliable than most methods, and easy of application in any class among the insane. With strict aseptic precautions, he believes the danger to be infinitesimal and so far has seen no injurious effects.

35 *Physiology and Pathology of the Digestion of Fat in Infancy. F. B. Talbot, Boston.
36 *Bacteriology of the Blood in Early Life. F. S. Churchill and C. P. Clark, Chicago.
37 *Metabolism of Nitrogen, Phosphorus and the Purin Substances in the New-Born Infant. O. M. Schloss, New York, and J. L. Crawford, Troy, Texas.
38 *The Non-Specificity of the Cell Findings in the Spinal Fluid in Various Meningeal Conditions, Especially in Children. W. P. Lucas, Boston.

35. **Digestion of Fat in Infancy.**—Talbot points out that there is no doubt that large amounts of fat can do a great deal of harm to most babies. Such babies come under two classes—those which have a normal digestion and are unable to digest excessive amounts of fat, and those which have diminished powers of digestion and are unable to digest normal amounts of fat. So much attention has been paid to the few babies that are unable to digest fat, that one is apt to forget that most babies can digest fat within reasonable limits. In Talbot's experience, it has been safe to increase the percentage of fat gradually up to 4 per cent. in most normal babies whose digestive powers have not previously been lowered by gross errors in feeding or by infection. These children develop normally without any of the signs or symptoms of fat indigestion so long as their hygiene is perfect and they have no intercurrent infection.

36. **Bacteriology of the Blood.**—Churchill and Clark made sixty-nine examinations on sixty-four infants and children during life, and studied sixteen cases post mortem. The blood was obtained by the usual method—from the median basilic vein just above the elbow. In two cases of suspected typhoid it was obtained from the lobe of the ear, as recommended by Peabody. Various kinds of syringes have been used, but the Luer glass syringe has been the most satisfactory. The blood thus obtained has been mixed immediately at the bedside with various media: in most of the cases two tubes of bouillon, two of agar and agar plates have been inoculated. In five of the typhoid cases, ox bile has been used in the medium, with positive results in all. A case of suspected typhoid in which bile medium was used was negative, but proved later to be a case of tuberculous meningitis. In the sixty-nine examinations made, the authors obtained nineteen positive results. Combining Rotch's series, their own and a few scattering reports in the literature, the authors found thirty-one cases of typhoid fever, in twenty, or 66 per cent. of which, bacilli were found in the circulating blood. Furthermore, the bacilli were found as early as four days before the onset of symptoms and as late as the twenty-second day. These results were obtained with all kinds of media and at all periods of the disease. Of fifteen cases of lobar pneumonia and three of lobular pneumonia, four of the former were positive and one of the latter, the organism found being the pneumococcus in every instance. Thus in the eighty-five cases comprising their own and Otten's series, thirteen, or 15 per cent., showed pneumococci in the circulating blood.

In the group of rheumatic affections, they included cases of endocarditis, arthritis, tonsillitis and chorea, these manifestations occurring either singly or in combination with each other. There were seven cases of endocarditis; all had chronic endocarditis; in five of the cases, the cultures were taken during a febrile stage, due either to tonsillitis, arthritis, or to an unknown cause, possibly an acute exacerbation of the chronic endocarditis. There were two cases of chorea, and in both of these the temperature was normal when the cultures were taken. Cultures were negative in all seven of the cases. They examined four cases of meningitis with two positive results. In the tuberculous case the patient was examined on the tenth day of the disease as a suspected typhoid patient. One case each of pyelitis, erysipelas and acute nephritis gave negative blood-cultures. Catheterized specimens of urine from the cases of pyelitis and acute nephritis showed a streptococcus in the former and nothing in the latter. One case of acute lymphocytic leukemia showed the streptococcus in the blood one week before death.

They have reports on the bacteriology of the heart's blood in seventeen cases, of which thirteen showed positive results. Three cases of special interest were one each of hemorrhagic disease of the newly born, erysipelas and status lymphaticus. The hemorrhagic disease showed in the heart's blood the *Staphylococcus aureus*, the *Bacillus coli*, the streptococcus and an unidentified diplococcus midway between the pneumococcus and the streptococcus. Of the four cases with a sterile heart's blood, three were as follows: a pyelonephritis due to the *B. pyocyaneus*, an otitis with a general septicemia, but with entirely negative post-mortem results, and a meningococcic meningitis. The fourth case was endocarditis in which the antemortem blood was also sterile. The organisms recovered post mortem were as follows: the staphylococcus six times (*S. aureus* five times, *S. albus* once), the streptococcus eight times, *Bacillus coli* three times, the *Diplococcus lanceolatus* one time, and an unidentified diplococcus.

37. **Metabolism of Nitrogen.**—Uric acid infarct elements were present in the urine of each of nine new-born infants examined by Schloss and Crawford. They state that the uric acid output in new-born infants is both absolutely and relatively high. It is greatest during the first three days and then decreases. In cases in which the umbilical cord was ligated late, the output of uric acid was greater during the second and third days than in cases in which the cord was ligated immediately after birth. The quantity of the purin substances in the colostrum ingested is too small to explain the observed high uric acid output. The total phosphorus excretion was high during the first three days and then showed a sharp diminution. There is marked retention of phosphorus by the new-born infant. There is a moderate nitrogen retention during the first three days of life; later, nitrogen is retained in large degree. There is an inverse ratio between the leukocyte count and the elimination of phosphorus and uric acid during the first few days of life. In the light of present knowledge, the parallelism between the excretion of uric acid and phosphorus during the first three days would seem to indicate a common origin from cell nuclei. The greatest excretion of uric acid in the late ligation case suggests that the formed elements in the blood in some way serve as its origin.

38. **Non-Specificity of the Cell Findings.**—From Lucas' study, it is evident, first, that there are many conditions that give the same cytologic findings in the spinal fluid: (a) encephalitis, (b) epidemic myelo-encephalitis, (c) meningismus, (d) tuberculous meningitis, (e) syphilis of the central nervous system; second, that the presence of mononuclear cells, or lymphocytes, in the spinal fluid cannot be the basis for a diagnosis of tuberculous meningitis; third, that the recovery from animal inoculation, or the finding of the tubercle bacillus microscopically are the only positive means of making the diagnosis of tuberculous meningitis; fourth, that the study of the spinal fluid, although very important, must go hand-in-hand with more careful clinical studies of such border-lying cases as the ones shown in the different tables.

44. **The Appendix.**—This series of cases studied by MacCarty and McGrath confirms the percentage of obliteration found in the appendix by other observers. Obliteration seems to occur as the result of an inflammatory process as shown by its histology, the time of occurrence, its irregularity of occurrence, the duration of the process, and the higher frequency in appendicitis than at necropsy is general. Many appendices become acutely inflamed during the process of obliteration and therefore an obliterated appendix should be removed, if possible. Carcinoma may occur at practically any age. It was impossible to make the diagnosis of carcinoma from the external appearance in 77 per cent. of the cases of carcinoma. The high frequency of carcinoma in obliterated or partially obliterated appendices may demand removal of all partially or completely obliterated appendices. Carcinoma of the appendix occurs in association with changes in the appendix which are related to the process of obliteration. Carcinoma of the cecum probably arises from the appendix only in a very small percentage of the cases.

46. Abstracted in The Journal, Jan. 28, 1911, p. 298.

47. **Teratoma Testis and Its Derivatives.**—The conclusion drawn by Ewing from the study of teratoma testis would seem to have important bearing on the origin of tumors in general. It seems unlikely that the conditions surrounding the genesis of this group of tumors are wholly different from those prevailing with tumors in other organs, notwithstanding the fact that in the testis one has to deal with "totipotent" sex cells not occurring elsewhere. In the testis one enocunters a wide variety of neoplasms, from the most undifferentiated, diffusely growing, highly malignant, round cell tumors, up to fully adult and harmless tissues and organs, all of which appear to have one and the same origin, the slow or rapid unfolding of original potencies of sex cells. These facts seem to Ewing wholly irreconcilable with any relation to any external parasite, but reveal in a striking manner that most important of all facts known about the origin of neoplasms—that embryonal cells possess more than any others the essential factors in the inception of tumors.

48. Abstracted in The Journal, Jan. 21, 1911, p. 218.

51. **Surgical Treatment of Undescended Testicle.**—The principle of Davison's operation depends on the direction of the spermatic vessels immediately above the beginning of the spermatic cord at the internal inguinal ring and the possibility of lowering the whole cord by the transplantation of these vessels. The operation consists of the following technic: The inguinal canal is exposed by dissection as in the Bassini operation for inguinal hernia. The testicle and cord are freed from the inguinal canal and ring and temporarily laid above the wound out of the operation field. The treatment of the posterior wall of the inguinal canal is very similar to that in the Fowler operation for inguinal hernia. After a preliminary double ligature of the deep epigastric hernia, an incision is made through the posterior wall of the inguinal canal, from the internal inguinal ring to the pubic bone just beneath the site of the external ring. This destroys the internal inguinal ring and exposes the peritoneum with the vas deferens and spermatic vessels lying on it attached by loose cellular tissue. When congenital hernia is present or the processus vaginalis is patulous, the peritoneal layer is carefully separated from the cord and cut across. The distal part is allowed to cover the cord and testicle. The opening in the peritoneum is closed. The reduplicated vas deferens is easily separated by gauze dissection from the peritoneum until the desired length is attained. The external edge of the cut transversalis fascia is sharply retracted outward, exposing the spermatic vessels for some distance. The preservation of these structures with the natural blood-supply gives the best prospect of the physiologic and functional development of the testicle.

A bed for the testicle is made in the scrotum. A silkworm-gut suture is passed through the gubernaculum testis and both ends are passed through the most dependent part of the scrotum. The testicle is located in the scrotum. The cut in the transversalis fascia (the posterior wall of the inguinal canal) is repaired. The cord is made to come through at the lower angle of the incision. The internal inguinal ring is closed. The conjoined tendon is sutured to the under side of Poupart's ligament above the cord. The fascia of the external oblique muscle is sutured to the edge of Poupart's ligament above the cord. The skin wound is closed. A strip of adhesive plaster is placed around the thigh just above the knee, with a flap on the inner side of the thigh. To this flap is fastened a thin rubber letter band. The suture through the bottom of the scrotum is tied to the rubber band with only sufficient tension to make the band taut. The usual aseptic dressings are applied. A light plaster-of-Paris body cast or starch dressing is used to prevent flexion of the thigh and intermittent traction on the gubernaculum testis. The operation should be performed by election at puberty.

52. **Complete Amenorrhea.**—The patient was a Greek woman, about 40 years old, in good physical condition, of average size and development of body, with no evidence of defects of any kind, and with good average intelligence. She made some very minor complaints suggestive of that train of nervous troubles frequently accompanying the menopause. During the examination the fact was brought out that the woman never had menstruated in her life, that she had given birth to eleven children, five of whom were living at time of this examination; further, that the grandmother of the patient had never menstruated in her life, that the mother of the patient had menstruated only once in every one or two years. Of the patient's children, one, a girl of 14 years, had not yet menstruated. The patient herself was married at the age of 15 and gave birth to her last child four years ago. Patient further said she had never had symptoms of a menstrual molimen of any sort whatever, no knowledge of when her menstrual time might be due, no malaise, no pain, nothing, in fact, saying that she simply lived like a man and didn't know what it was to be sick.

55. **Hydrostatic Dilatation of the Cervix Uteri.**—Hirst has had made two new bags in three different sizes, one a flattened hour-glass, for the effaced cervix, the other a spool-shaped bag for the uneffaced cervix; the first, 2 inches; the second, 2½ inches deep, both having minimum transverse diameters of 1, 2 and 3 inches. These bags are attached to the blood-pressure apparatus so as to measure, decrease, increase or maintain at one level the pressure exerted by them.

76 Supervision of the Venereally Diseased. G. V. R. Merrill, Elmira.
77 *Varicose Ulcer and a Method of Treatment. F. W. Lester, Seneca Falls.

67. **The Ideal Medical Education.**—The propositions made by Duane are summarized in the following ideal sketch of what he hopes to see obtaining in the future:

1. The ideal medical course will be based on or rather will contain a large number of humanistic studies, comprising prominently Greek, Latin, English, history, economics, psychology and drawing.

2. These humanistic studies will be pursued side by side with the technical work and will be treated as of equal importance. This coordination of the two will be best effected by a combined liberal arts and technical course leading to the degrees of A.B. and M.D. This course will comprise sixty months of actual work which can well be compressed into six years.

3. For the ordinary medical student intending to become a general practitioner, some of the technical work now required (especially in the laboratory) will be eliminated—its place being taken by clinical work or by humanistic studies.

4. The medical course will begin and end earlier. This can be effected by making the work in the preparatory schools less diffuse and more thorough, and by lengthening the terms, both in the schools and in the university, from eight months to ten. In that case the student will begin his combined course at 16, get his A.B. at about 20 and his M.D. at 22.

5. Teaching, so far as possible, will be made individual. This will probably be best attained by the appointment of numerous preceptors. Each preceptor will have charge of four or five students, and it will be his business to see that they understand their work and that they do it properly. His relations with them will be intimate and informal.

6. The student will enter on elementary clinical work early in his course and even before he receives any didactic instruction on the theory and treatment of disease.

7. Clinical work will be graded. Step by step the student will learn to handle cases for himself. Under the guidance of his clinical preceptor cases will be put under his care, whose course he will follow day by day. As his experience increases he will be accorded more responsibility and a freer hand, until at the end of his course he will be competent to diagnosticate and treat any ordinary cases of disease. When he receives his degree he will not need a supplementary hospital course in order to qualify himself for practice.

8. The university will have its own hospital, which shall be completely under its control and which shall be officered by its own preceptors.

9. The university will provide all sorts of elective courses in all branches for undergraduate and postgraduate work. The selection of these by students will be strictly regulated, and only a very limited number can be taken by any one man before graduation. After graduation it will be possible for the student to get at his university the most detailed instruction and the fullest practical work in any medical subject.

10. The student will be systematically encouraged to do original work. Efficient aids to this end will be the plan of individual teaching and of individual clinical work here advocated, together with a wise application of the elective system.

11. The thesis will be restored as a requirement of graduation. In the combined course the student will present two theses—one on a non-technical subject for the degree of A.B., the other on a medical topic for the degree of M.D. In either case the thesis will count as the equivalent of an examination in a major subject.

12. The university will give ample postgraduate instruction in all departments of medicine: (a) For the benefit of graduates, especially those aiming to be country practitioners, who without desiring to be specialists, yet wish to be more or less conversant with several specialties; (b) for graduates who wish to pursue some special line of research or get special information in any field: (c) for those wishing to become specialists.

13. To the specialist the university will give an adequate, systematic and thorough training. It will require of him: (a) That he take certain specified electives either in the undergraduate course or in the postgraduate year; (b) that he spend at least two years after graduation in general medical and surgical work (preferably in a hospital); (c) that he afterward spend a full year in postgraduate work at the university in the theory and practice of his specialty; (d) that he present a thesis on some subject connected with his specialty: (e) that he pass a satisfactory examination in the theory and practice of his specialty.

14. On his fulfilling these requirements the university will confer on him the degree of Ph.D.

77. **Varicose Ulcer.**—The method to which Lester refers is as follows: Using adhesive plaster strips in lengths of from 12 to 18 inches, and from ¾ to 1 inch wide, envelop the leg in a net-work of the plaster strips, extending entirely around the leg, from the foot to just below the knee. These strips are applied tightly enough to ridge deeply into the edematous skin, and applied spirally, in both directions, so that when completed, the leg will present a checkered appearance and look as if small squares were attempting to burst through. The first strip encircles the foot itself, and extending in a spiral manner up the leg; the second, beginning on the opposite side of the foot and crossing the first strip, proceeding on up the leg, in a spiral opposite in direction to the first. so the strips are applied, about 1 inch apart, up the leg, crossing the ulcer as they happen to come, which, having been cleansed with pure olive oil or a solution of liquor cresolis compositus or phenol (carbolic acid), and dusted with calomel, is partially or entirely strapped under. Several thicknesses of sterile gauze may be then placed over the straps covering the ulcer, and a firm muslin bandage applied. The bandage should be removed and reapplied every morning, the gauze being renewed if soiled, but the straps left on for a longer period—from two to seven or eight days. The results of this treatment have been uniformly satisfactory to Lester, as a decided improvement may be noted almost from the first, and in a period of from two to four weeks, the ulcer is closed.

111 *Normal Saline Solution Given Through a Biliary Fistula M. J. Ford, Omaha, Neb.

110. **Poisoning Following Use of Coal-Tar Derivatives.**—For four years, Overgaard's patient had been a constant user of acetanilid, and would use as many as a dozen 5-grain tablets in twelve hours. She procured 1,000 at a time, and in the four years had used several thousand. She suffered from severe

headaches and vomiting attacks lasting for two or three days and as a rule she would have to be in bed. About two years ago, she began the use of morphin together with the acetanilid and is now using as much as 2 grains of morphin a day to get relief. When first seen by Overgaard, she had been in bed for six weeks, was emaciated, no appetite on account of persistent vomiting, headache always present, slightly jaundiced with marked tenderness and dulness over the gall-bladder region, very constipated and suffering from tympanitis. Dr. A. F. Jonas drained the gall-bladder of dark, thick, stringy bile. She made a good recovery from the effects of the operation, and in three weeks was up and around a little. She stopped the use of any drug and in a couple of months was doing her work and feeling fine. In about a year and a half Overgaard was again called to see her and found her in bed suffering from headache, vertigo, faintness, tinnitus, psychic irritability, dyspnea, palpitation and edema. There was also tenderness over the gall-bladder region and large quantities of bile and mucus were being vomited. She was using coal-tar products and morphin to relieve the pain. Her lips and finger nails were blue. She had lost about 20 pounds in weight during from four to six weeks. Overgaard says that the thing for the profession to do is to enlighten the public on the bad results arising from the use of these coal-tar products and to discourage the continued self-medication of the laity by the use of all kinds of headache tablets and powders.

111. **Normal Saline Solution Given Through a Biliary Fistula.**—Ford reports a case of cholecystitis in which 2 pints of normal saline solution were given daily for a week through a biliary fistula. A diagnosis of gall-bladder disease was made from the findings. Ford operated. The gall-bladder was distended to twice its usual size. One inch from the fundus was what appeared to be a sort of a diaphragm of very thick adhesions—the trocar would not go through without using considerable force. There were no gall-stones, but the gall-bladder was full of black, tarry, ropy bile. Ford curetted the gall-bladder—put in a rubber tube drain and ordered the patient put to bed in Fowler's position and given normal saline by rectum. There was practically no drainage, just a little bloody pus. The patient grew persistently weaker, and could not retain saline by bowels which were moving involuntarily. Four days after the operation, Ford started to give saline solution through the drainage tube in the gall-bladder. It took three hours for the pint of normal saline to run in. Some time later the patient had considerable distress in the stomach which was relieved by lavage with a solution of sodium bicarbonate. On the following day 2 pints of saline solution were administered through the tube into the gall-bladder, one in the morning and one in the afternoon. The patient continued to improve from the first time the saline was given by the biliary fistula. The improvement was continuous and as the patient gained in strength the bile began to flow through the fistulous opening and continued for about four weeks when the fistula closed of its own accord.

3. **Chronic Jaundice.**—By a timely and correct diagnosis, such as is possible from a careful consideration of the clinical history and symptoms, and the information to be obtained by thorough analysis of the urine and feces, Cammidge says the complications and sequelæ likely to arise in cases of chronic jaundice—serious disease of the pancreas, cholangitis, cirrhosis of the liver, etc. may be avoided. Delay is always dangerous, and it is useless to await developments until the case is of interest only to a pathologist. The cause of the jaundice must be determined at the earliest possible moment and the treatment be based on the conclusion arrived at. A diagnosis of gall-stones obstructing the bile duct, made on the clinical data and confirmed by an examination of the excreta, calls for immediate operation, as the only likely spontaneous cure is Nature's crude and dangerous remedy of making a fistula by which the stone may escape into the duodenum, or elsewhere. Catarrhal jaundice frequently clears up spontaneously, but if after six weeks of rest in bed, with dieting and medical treatment, the jaundice persists and the urinary "pancreatic" reaction is positive, it is advisable to invoke the aid of the surgeon to perform a short-circuiting operation to avoid further damage to the pancreas. In the last stages of malignant disease operation is only likely to shorten the brief span of life still left to the patient, but in the earlier stages much may be done to make existence more bearable by a cholecystotomy or cholecystenterostomy to relieve the intolerable itching of which complaint is chiefly made. 67. The Ideal Medical Education.—The propositions made by Duane are summarized in the following ideal sketch of what he hopes to see obtaining in the future:

1. The ideal medical course will be based on or rather will contain a large number of humanistic studies, comprising prominently Greek, Latin, English, history, economics, psychology and drawing.
2. These humanistic studies will be pursued side by side with the technical work and will be treated as of equal importance. This coordination of the two will be best effected by a combined liberal arts and technical course leading to the degrees of A.B. and M.D. This course will comprise sixty months of actual work which can well be compressed into six years.
3. For the ordinary medical student intending to become a general practitioner, some of the technical work now required (especially in the laboratory) will be eliminated—its place being taken by clinical work or by humanistic studies.
4. The medical course will begin and end earlier. This can be effected by making the work in the preparatory schools less diffuse and more thorough, and by lengthening the terms, both in the schools and in the university, from eight months to ten. In that case the student will begin his combined course at 16, get his A.B. at about 20 and his M.D. at 22.
5. Teaching, so far as possible, will be made individual. This will probably be best attained by the appointment of numerous preceptors. Each preceptor will have charge of four or five students, and it will be his business to see that they understand their work and that they do it properly. His relations with them will be intimate and informal.
6. The student will enter on elementary clinical work early in his course and even before he receives any didactic instruction on the theory and treatment of disease.
7. Clinical work will be graded. Step by step the student will learn to handle cases for himself. Under the guidance of his clinical preceptor cases will be put under his care, whose course he will follow day by day. As his experience increases he will be accorded more responsibility and a freer hand, until at the end of his course he will be competent to diagnosticate and treat any ordinary cases of disease. When he receives his degree he will not need a supplementary hospital course in order to qualify himself for practice.
8. The university will have its own hospital, which shall be completely under its control and which shall be officered by its own preceptors.
9. The university will provide all sorts of elective courses in all branches for undergraduate and postgraduate work. The selection of these by students will be strictly regulated, and only a very limited number can be taken by any one man before graduation. After graduation it will be possible for the student to get at his university the most detailed instruction and the fullest practical work in any medical subject.
10. The student will be systematically encouraged to do original work. Efficient aids to this end will be the plan of individual teaching and of individual clinical work here advocated, together with a wise application of the elective system.
11. The thesis will be restored as a requirement of graduation. In the combined course the student will present two theses—one on a non-technical subject for the degree of A.B., the other on a medical topic for the degree of M.D. In either case the thesis will count as the equivalent of an examination in a major subject.
12. The university will give ample postgraduate instruction in all departments of medicine: (a) For the benefit of graduates, especially those aiming to be country practitioners, who without desiring to be specialists, yet wish to be more or less conversant with several specialties; (b) for graduates who wish to pursue some special line of research or get special information in any field: (c) for those wishing to become specialists.
13. To the specialist the university will give an adequate, systematic and thorough training. It will require of him: (a) That he take certain specified electives either in the undergraduate course or in the postgraduate year; (b) that he spend at least two years after graduation in general medical and surgical work (preferably in a hospital); (c) that he afterward spend a full year in postgraduate work at the university in the theory and practice of his specialty; (d) that he present a thesis on some subject connected with his specialty; (e) that he pass a satisfactory examination in the theory and practice of his specialty.
14. On his fulfilling these requirements the university will confer on him the degree of Ph.D.

77. Varicose Ulcer.—The method to which Lester refers is as follows: Using adhesive plaster strips in lengths of from 12 to 18 inches, and from ¾ to 1 inch wide, envelop the leg in a net-work of the plaster strips, extending entirely around the leg, from the foot to just below the knee. These strips are applied tightly enough to ridge deeply into the edematous skin, and applied spirally, in both directions, so that when completed, the leg will present a checkered appearance and look as if small squares were attempting to burst through. The first strip encircles the foot itself, and extending in a spiral manner up the leg; the second, beginning on the opposite side of the foot and crossing the first strip, proceeding on up the leg, in a spiral opposite in direction to the first, so the strips are applied, about 1 inch apart, up the leg, crossing the ulcer as they happen to come, which, having been cleansed with pure olive oil or a solution of liquor cresolis compositus or phen[illegible] and dusted with calomel, is partially or entirely strapped under. Several thicknesses of sterile gauze may be then placed over the straps covering the ulcer, and a firm muslin bandage applied. The bandage should be removed and reapplied every morning, the gauze being renewed if soiled, but the straps left on for a longer period—from two to seven or eight days. The results of this treatment have been uniformly satisfactory to Lester, as a decided improvement may be noted almost from the first, and in a period of from two to four weeks, the ulcer is closed.

111 *Normal Saline Solution Given Through a Biliary Fistula. M. J. Ford, Omaha, Neb.

110. Poisoning Following Use of Coal-Tar Derivatives.—For four years, Overgaard's patient had been a constant user of acetanilid, and would use as many as a dozen 5-grain tablets in twelve hours. She procured 1,000 at a time, and in the four years had used several thousand. She suffered from severe

prophylaxis. The cases of afebrile typhus which have been occasionally reported he regards as merely the stage of convalescence from an attack, the febrile phase of which escaped recognition. Another point which increases the difficulty of differentiating exanthematous typhus is its liability to be confounded with the eruptive forms of malaria.

54. **Rice Bran in Prevention and Treatment of Beriberi.**—Breaudat and Denier report from the Pasteur institute at Saigon in Indo-China that rice bran seems to remove the cause of beriberi and prevent its development. They gave the bran in the form of pills mixed with syrup and peppermint, about 40 gm. of the bran being thus added daily to the ordinary food. It never caused any digestive disturbance while it had a marked curative action, equal to that of any drug. There were 210 native soldiers who took the pills in prophylaxis including thirty-seven who had had beriberi, and there were forty-nine who had had it in 311 controls. Between September 15 and February 1 no cases of beriberi developed among those taking the bran, while 17.4 per cent. of the controls had it. The action of the bran was less pronounced in those who had already had the disease.

57 Poliomyelitis with Meningeal Symptoms. L. Benard and Maury.
58 Streptococcus Origin of Scarlet Fever. M. Thomas.
59 Insufficiently Fed Infants. (Troubles causés par l'hypoalimentation des nourrissons.) G. Variot.

56. **Unrecognized Diphtheria.**—Terrien thinks that in many cases of so-called malignant diphtheria the infection had been installed for some time in a more inaccessible region and had thus escaped discovery; only when it reached the throat was it recognized, and then it was in such full swing that no means were able to arrest it. Glatard, in 1902, was able to collect 333 cases of primary nasal diphtheria, in most of which the infection had escaped recognition. Faseuille has recently called attention to its frequency in infants, and warns that any rather severe and persisting coryza in an infant should suggest diphtheria, even when no false membranes can be discovered. Kuhn, Gallo and Abrand have each encountered a case in which the diphtheria persisted almost latent in a babe; one had only slight fever and sore throat but it finally sneezed a tube of membrane out of its nose. Schaps found a serous, blood-stained discharge from the nose and excoriation of the upper lip as the only manifestation of diphtheria in nine infants. In four cases reported by Dupont the membrane formation was restricted to the nasal fossæ and did not invade the throat. Adenoid vegetations may also be the primary and the sole seat of the diphtheria process; Rocaz has encountered ten such cases. This primary and localized diphtheritic adenoiditis seems to be unusually virulent; the extent of absorbing surface is exceptionally large and the general symptoms are severe, in contrast to the mild general symptoms with the primary nasal form. The unusual gravity, the rapid course, the difficulty of recognizing the affection, all conspire to enhance the danger of diphtheritic adenoiditis. It should be suspected when the child shows signs of adenoiditis, earache and hoarseness, the nose being stopped up but without the discharge of coryza. Then follow the general symptoms, such as extreme lassitude and pallor, swelling and tenderness of the glands in the neck and the rapid pulse even when there is no rise in temperature. The laryngoscope or bronchoscope was the only means of detecting the process in some of the cases cited. For bacteriologic examination the material must be taken from behind the velum, through the nose, inoculating several tubes.

63 *Preventive Vaccination Against Typhoid. H. Vincent.
64 Prophylaxis of Small-Pox in French Colonies in Africa and Indo-China. Kermorgant.

60. **Female Pseudohermaphrodites.**—In the case reported, the patient had been brought up as a man and was apparently happily married, when an ovarian sarcoma had to be removed. In discussing the case, Magnan and Pozzi suggest a classification for pseudohermaphrodites based on the feminine or masculine aspect. They suggest the term gynoid for the former and android for the latter, prefixing "andro" or "gyn" to designate the histologic sex. The irregular hypospadic andro-gynoid type is the most frequent, and is readily confirmed by discovery of the testicles. The gyn-android type is rare; the case reported is of this type with inversion of the genital sense.

61. **The Plague.**—Chantemesse compares the conditions in Manchuria now with those in an epidemic of plague thirty-two years ago in southern Russia. In the latter epidemic some villages along the Volga were affected with a strange disease, and after the death of the physicians and local authorities the terror-stricken peasants took matters into their own hands, shutting off the infected houses and permitting no one to enter or leave them or to enter the villages from without. These rude, illiterate peasants, in 1878, took instinctively the proper measures in regard to isolation, and the epidemic soon died out from lack of fuel. The dead were hauled with long-handled hooks to the pits dug for them, and any one suspected of having been in contact with the sick was not allowed out of the house for twenty days. By the time the national authorities took a hand in quarantining the villages the epidemic had died out after having caused 500 deaths. Far different are the conditions in Manchuria to-day. The people hid their sick when the plague first appeared among them, and thus the epidemic got a firm foothold in many places before its existence became known to the authorities. Trappers in the region east of Lake Baikal had collected a number of skins of the land otter, or tarabagan, common along the rivers of Siberia. Schottelius of Stuttgart, Germany, called attention some time ago to the peculiar susceptibility of this animal to the plague. [*Public Health Reports*, March 10, states that it is a marmot, related to the American woodchuck and the prairie dog, and that 10,000 trappers were in the field last year to get the skins.] Chantemesse says that the existence of the plague among these animals was known and also the fact that it assumed the pneumonic form in them. The hunters in question had collected a number of pelts; in October these hunters developed plague and it spread among the Chinese inhabitants of the region. The latter fled eastward in their fright, seeking refuge in Manchuria but concealing the fact of the infection until the epidemic had assumed extensive proportions. The infection is extremely virulent; Haffkine has been in Manchuria since December and he states that he has not known of a single recovery. None of the 130 persons he has vaccinated there against plague has contracted the disease although constantly exposed—omitting those vaccinated after the infection was already installed.

One of the principal questions still to be decided is the length of the incubation period. Winter is the plague season. Another remarkable feature of the plague, Chantemesse adds, is that when the disease is once installed in a place it seems almost impossible to eradicate it. In Egypt, for instance, notwithstanding the strictest measures, the disease maintains its foothold, and the number of cases has increased constantly from 99 in 1899 to 640 in 1906, and since then from 500 to 1,500 cases yearly, with 118 cases already in 1911, but the type of plague is mild there. In regard to the destruction of rats on shipboard, Chantemesse remarks that the results are exactly proportional to the zeal and conscience of those doing the work and proportional to the strictness of the supervision over them by the authorities in charge.

63. **Preventive Vaccination Against Typhoid.**—The Académie formally adopted a resolution advocating preventive antityphoid vaccination under certain conditions. The text of the resolution was given in the Paris Letter in THE JOURNAL, February 25, page 601.

65 *Treatment of Megacolon in Adults. G. Gayet and M. Patel.
66 *Autoplastic Method of Treating Hypospadias. Cantas.

65. **Hirschsprung's Disease in Adults.**—Gayet and Patel warn that medical measures should not be continued too long if the patient is not improving, otherwise he will be in bad condition for an operation if this becomes necessary. The medical measures should be those for obstinate constipation in general except that drastic purgatives should be avoided. The only drug that seems to have done any good is morphin; this acts by abolishing spasmodic contraction. Seven different operations may be applied and the authors review series of cases of each type, totaling forty-one, some of them not previously reported. Sometimes an exploratory laparotomy reveals torsion and other mechanical conditions which it is easy to remedy without the knife or merely with a colopexy. This partial operation is liable to fail, however; probably many failures in this category have not been published. The best plan is to make an artificial anus at once. This can be done easily and rapidly, they say, if the appendix is utilized to make the new anus; this proved successful in two very serious cases in their experience. When the disturbances from obstruction have subsided, the way is cleared for radical operation on the enlarged colon. When the patient is robust and the colon is very much enlarged, they advise inserting the ileum in the terminal portion of the sigmoid flexure, excluding the abnormal part of the bowel altogether. Sometimes an abdominal tumor is the only finding. When the supposed tumor proved to be feces impacted in the enlarged colon, they have found it possible in some cases to manipulate the fecal masses toward the natural anus after the abdomen has been opened. If the masses are stony hard, this measure is not advisable as the intestine is liable to become injured thereby. Enterotomy should be reserved exclusively for cases of this kind unless enterectomy at once is deemed preferable.

66. **Autoplastic Treatment of Hypospadias.**—Cantas cuts a skin flap in the thigh, including in it a stretch of the internal saphenous vein. This flap is twisted around and the vein utilized to make the urethra. He reports a case in which this technic was successfully applied.

69 *Hexamethylenamin in Treatment of Acute Biliary Infections and of Typhoid Fever. (L'urotropine dans le traitement des infections biliares aigues et de la fièvre typhoide.) A. Chauffard.
70 *Should Women in Eclampsia Nurse Their Infants? R. de Bovis.

69. **Acute Biliary Infections in Typhoid Fever.**—Chauffard is convinced that if careful search were made for signs of acute infection of the gall-bladder and bile ducts in typhoid fever, infectious processes in this region due to the typhoid bacilli would oftener be discovered. He has encountered a number of such cases, as he relates in detail, and discusses whether it might not be possible to give some drug which is eliminated in the bile and might thus act directly on the angiocholecystitis. The latter condition is a frequent source of typhoid relapses and may leave the patient a chronic carrier. Recent research has shown, he says, that hexamethylenamin is eliminated in the bile and thus it can sterilize the biliary passages while it cures the bacilluria at the same time. He has been much impressed with the promptly favorable modification in typhoid fever which followed exhibition of 0.5 gm (7.5 grains) of the hexamethylenamin three times a day. One patient was a youth of 15 with chills and high fever, tenderness and discomfort in the right hypochondrium, all developing the twenty-second day of a mild typhoid. The temperature chart shows the prompt benefit which followed this medication.

70. **Should Women with Eclampsia Nurse Their Infants.**—De Bovis concludes from some recent reports that it is best to draw and throw away the milk of women with eclampsia developing after delivery as it is liable to prove toxic for the infant for a few days. After the toxins have been more or less perfectly eliminated the child can be put to the breast. It is probable, he thinks, that every parturient is in a condition of auto-intoxication to a certain extent, and it is possible that the milk attracts the toxins of eclampsia as it seems to attract arsenic. When the eclampsia develops before delivery, the toxins are more liable to be eliminated by the time the infant is ready to nurse than when the eclampsia does not come on until after the child is born.

82 *Induced Pneumothorax in Pulmonary Tuberculosis. III. L. Brauer and L. Spengler.

82. **Induced Pneumothorax in Tuberculosis.**—This volume of 336 pages contains the detailed account of eighty-three cases, bringing the total to 102 in which Brauer and Spengler have compressed the lung by an artificially induced pneumothorax in treatment of unilateral pulmonary tuberculosis. The work was done at the medical clinic at Marburg or the Davos sanatorium, and this forms the third memoir on the subject. The volume is dedicated to Professor Erb on his seventieth birthday. The material is arranged and numbered so that a complete oversight of the cases is possible in these and in future later reports. Complete recovery was obtained in a number of cases in which, they are convinced, it would have been impossible to realize similar benefit by other measures. They are becoming more and more certain that with careful selection, in the moderately severe cases this collapse therapy, as they call it, when conditions permit will give excellent results. As pioneers in this field, however, they feel bound to extreme caution and reserve and consequently they think the measure must stand its highest test in the severer cases so that its dangers and shadows may be fully appreciated. Then it can be applied in the milder cases with courage and confidence. A number of Roentgen-ray pictures and curves are appended.

or other disturbance in the intima of the vessel and some disturbance in the circulation of the blood are indispensable factors in the development of thrombosis. It has been encountered not only in the course of heart and vascular disease, marasmus, cancer, phthisis, syphilis and acute infectious disease, but also in acute and chronic suppurations, especially appendicitis and otitis, pyemia and poisonings. The localization and course of the thrombosis are peculiar in anemia, leukemia and chlorosis, as he shows by a number of examples from the records. By far the largest proportion of cases of thrombosis, however, develop in connection with operations and deliveries, but a few cases are on record of thrombosis following trauma, sometimes quite slight, and he reports an instructive case of this kind in a robust young man who had been riding an unruly horse. The strain on his arms was the probable cause of the thrombosis which suddenly developed in the left subclavian, axillary and brachial veins. Schepelmann assumes that the traction on the veins in the arm must have injured the intima; a predisposing factor existed in bradycardia from a slight cardiac defect; in youth the patient had had diphtheria, articular rheumatism and a furuncle in the ear.

135 Harelip with Cleft Palate. (Behandlung der mit Wolfsrachen komplizierten einseitigen Hasenscharten.) R. Drenkhahn.

128. Salvarsan in Non-Syphilitic Mouth Lesions.—Gerber presents clinical evidence to show that not only Vincent's angina but numerous other inflammatory affections of the mouth and throat are the work of spirochetes. Not only gingivitis but simple and mercurial stomatitis, scorbutus and possibly noma are the result of invasion by the spirochetes when a path is opened for them by minute lesions. Drugs that act on spirochetes have a curative influence, as he shows by three cases reported in which salvarsan proved effectual.

130. Permanent Cure of Tuberculosis with Induced Pneumothorax.—Spengler has now fifteen patients who can be regarded as clinically cured by the artificially induced pneumothorax. From nine months to four years have elapsed since the close of the treatment and the patients have neither fever, cough nor sputum while all are in prime working condition. The ages ranged from 11, 16, 17 and 18 to 31, 34, 35 and 43. The pneumothorax was maintained for from two months to five months in two cases, in three from ten to fifteen, and in four from eighteen to twenty-four months. Compare with Abstract 82, above.

133. Gonorrheal General Infection.—Leede reports a case which resembles one of Jadassohn's in which the urethra seemed to be intact and the general infection occurred through an erosion in the skin. Leede's case is one of the rare instances of fatal gonorrheal arthritis. A purulent hemorrhagic lesion in the ankle was the main source of the intoxication; Leede ascribes the severe general symptoms to a peculiar idiosyncrasy to the toxins generated by the gonococci. This was evidently responsible for the stupor, the cachexia, the extreme atrophy of the muscles, the desquamation and the fatty degeneration of the heart; the blood was constantly sterile. In another case the syndrome began about the same, the left elbow being the seat of the lesion. In this case he punctured the joint but without finding pus or effusion and then he opened the joint wide, allowing the escape of considerable edema fluid. This released the toxins in the focus and the patient soon recovered. No gonococci could be cultivated from the fluid in this last case. Leede's experience thus teaches the wisdom of ample opening up of the joint when gonorrheal arthritis is accompanied by great debility, emaciation, etc.

CHRONIC PANCREATITIS: ITS SYMPTOMATOLOGY, DIAGNOSIS AND TREATMENT

BASED ON A STUDY OF THIRTY-EIGHT CASES *

JOHN B. DEAVER, M.D., LL.D.
PHILADELPHIA

In the domain of pancreatic disease there still remains much unbroken ground. Uncertainties in pathology, obscurities in symptomatology and difficulties in diagnosis beset us and render our clinical judgments difficult and our therapeutics far from satisfactory. Only by the accumulation of accurate observations can the subject be cleared up, and it is desirable that each should add his personal experience. With this in mind I have reviewed those cases of chronic pancreatitis which have come under my personal observation during the past few years and of which my records are sufficiently complete to warrant their inclusion. For the laborious task of collecting and analyzing the cases I am indebted to two of my house doctors, L. C. Kinney and LeFevre Stewart, and to my assistant, Dr. D. B. Pfeiffer.

Of the various affections of the pancreas, those composing the group due to inflammation and its sequels are the most frequent and important. By reason of its protected situation, direct injuries to the pancreas are uncommon. Likewise, while it is subject to the various neoplasms affecting parenchymatous organs, there is no such tendency toward tumor formation as occurs in certain other parts of the body. The observations of recent years, however, made chiefly at the operating-table, have made it apparent that inflammatory changes are much more frequent than anyone had hitherto surmised. It was but natural that the most extreme grades of inflammation were the first to claim attention, and since the pioneer work of Fitz, the acute and subacute forms of pancreatitis have been clothed with a fairly definite pathology and symptomatology, though it is but just to say that our knowledge even here lacks completeness; and in the individual case the difficulties are many.

It is, however, when we approach the consideration of the lesser degrees of inflammatory change of chronic nature with their less characteristic clinical declarations, that we feel our ground often slipping and insecure. Fitz wrote understandingly of chronic pancreatitis and the chief additions to our knowledge since then have been made by Körte, Oser, Lancereaux, Opie, Moynihan, Robson, Cammidge, Truhart and Lazarus. Still most clinicians are agreed that the diagnosis of chronic pancreatitis is exceedingly difficult. The extremes of opinion in this respect are those of Opie, who holds that "the lesion is seldom associated with such definite symptoms that it is recognizable during life," and of Robson and Cammidge, who state that, "from the information obtained by a careful examination of the patient, a knowledge of the history of the case, and the results of a chemical and microscopic examination of the excreta, a correct opinion may be formed in a large majority of instances." My own feeling in regard to this matter is located somewhere between these pessimistic and optimistic expressions. Certainly the diagnosis has been made a sufficient number of times to demonstrate that it is not too difficult to attempt; but it is equally true that our present criteria are too uncertain and inconstant to warrant a claim for great accuracy. We must aim to improve our methods and our understanding. There are no pathognomonic symptoms, no short cuts to the diagnosis of chronic pancreatitis. It is to be made only by the solution of an equation, the factors of which are obtained by three separate lines of inquiry, viz:

1. The anamnesis.
2. The physical examination.
3. The special tests designed to show disturbances of pancreatic function.

I have divided my cases into two groups, according to the presence or absence of gall-stones. Of the seventy-three cases, in thirty-five there were stones in some portion of the biliary passages, and in thirty-eight there were none at the time of operation.

In these remarks I shall restrict myself to the non-calculous group, believing that these cases will give a truer picture of pancreatic disease *per se*. The cases with stones will be considered at another time. The series is still not entirely pure, since twelve had demonstrable changes in the gall-bladder at the time of the operation. Hence a certain admixture of biliary symptoms may be present in this analysis.

A careful history is of the first importance. Habits of eating or drinking which set up chronic inflammatory changes in the stomach and duodenum will be found in certain cases; in others a history of the infectious conditions which are especially likely to be followed by disease of the biliary passages. Often a history of antecedent, disregarded and perhaps forgotten indigestion is obtained. If disease of the bile-ducts and gall-bladder have preceded the pancreatic inflammation, the early history will partake of the inaugural symptoms of that disorder, and perhaps frank attacks of hepatic colic have occurred.

The relation of sex to chronic pancreatitis as compared with cholelithiasis is reversed. There were twenty-two males and sixteen females. This corresponds with Opie's figures, who found seventeen males and thirteen females. Bohm's large statistics also show that 65 per cent. occurred in the male sex. In view of the preponderance of biliary infections in the female sex, this fact is significant as showing that there must be some essential difference in the factors which produce infection in the ducts of these closely situated viscera. According to Desjardins, the same infection arising in the intestine and traveling up the bile and pancreatic ducts will, in the former situation, induce a stone-forming catarrh, but in the pancreas will cause a chronic interstitial inflammation. The lack of parallelism in the two kinds of infection, while not conclusive, creates a presumption against such complete similarity of origin in the majority of instances.

---

* Read before the College of Physicians of Philadelphia, March 1, 1911.

The incidence according to age is as follows:

Below 30	4
30 to 40	11
40 to 50	11
50 to 60	8

More than two-thirds of Opie's cases occurred between the ages of 40 and 60. In my series it is seen that the age is lower, two-thirds occurring between the ages of 30 and 50. This is accounted for by the fact that all but one of my cases were operative while Opie's statistics include post-mortem records.

The onset of symptoms is spoken of as sudden in twenty-five cases, gradual in thirteen; but these figures refer especially to exacerbations, premonitory symptoms being present in the majority of instances.

The leading and most constant symptom is pain, which was absent in only three cases. I am conscious of the fact that I am dealing with a series of cases that have been driven to surgical intervention. This magnifies the importance of pain as a symptom, for too frequently it requires suffering to bring a patient to the operating-table. The practitioner must see many cases of pancreatitis in which pain is absent or inconspicuous.

The pain of chronic pancreatitis, or its mild exacerbations, is not in itself characteristic. It varies from dull discomfort or ache to sharp lancinating or colicky pain quite like gall-stone colic. It may be merely a sense of fulness or oppression in the epigastrium. The pain was severe in twelve cases; moderate in twenty-one; in eleven it was colicky.

In the majority of cases when the pain was colicky in type the gall-bladder was diseased. In one instance several small stones had been passed *per vias naturales* a short time before, though none was found at the time of operation. It seems probable that by the dilatation of the ducts following passage of a stone, the gall-bladder had been enabled to empty itself of its calculous contents. From these observations I am inclined to interpret colicky pain, when present, as evidence of involvement of the bile passages. In seventeen cases the pain was located in the epigastrium; in fifteen beneath the right costal margin: in one beneath the left costal margin; in two it was lumbar, and in one severe exacerbation it was general. From the primary location radiation took place to the epigastrium in five; to the back in nine; to the right and left costal margin in eight and one cases, respectively, and to the right and left shoulders in nine and two cases, respectively.

No definite relation to eating or to any particular articles of food was brought out in this series. This seems to be of some value in differentiating pancreatic pain from that of ulcer of the stomach or duodenum and, to a less extent, from gall-bladder disease.

It has been observed that in some cases the carbohydrates are most likely to set up digestive disturbances and Sailer found that the administration of glucose for the purpose of testing the assimilation limit was particularly distressing to these patients.

But slightly less frequent than pain is the history of nausea or vomiting or both. Twenty-one of my patients had had attacks in which vomiting figured, while ten more had been nauseated without actually vomiting. Opie has called attention to the association of chronic interlobular pancreatitis and persistent vomiting, and cites four of his thirty cases, in which advanced chronic interstitial inflammation was found in individuals who during life had suffered with persistent vomiting. While I have not encountered vomiting lasting persistently over a considerable period of time, yet the prominence of nausea and vomiting occurring in attacks at variable intervals indicates its importance as a symptom of the more severe type of the disease.

In ten cases it occurred before the onset of actual pain. This may have been due to what Mayo has spoken of as "the association of surgical diseases in the upper abdomen," for we must always remember that pancreatitis is a disease which in the majority of instances is preceded by, or associated with, disease of the neighboring organs such as gastritis, duodenitis, or biliary catarrh. The vomiting of pancreatitis is non-characteristic, though often containing mucus and bile. Eructations of gas are common in this disease as in most other abdominal affections, and were specially mentioned as a distressing symptom in twelve cases.

The third important symptom is jaundice. This also, as a striking and intensely disagreeable thing for the patient, like pain, is apt to be magnified in importance in any operative series. It was present at the time of operation, or previously in twenty-four cases, absent in fourteen. Eleven patients were jaundiced when admitted. The mechanism of the production of jaundice is easily understood when it is considered that the common duct, in approximately two-thirds of all cases, courses through the head of the pancreas before reaching the duodenum. As this is the portion of pancreas which is most commonly affected by inflammation, it is to be expected that biliary drainage in a percentage of cases will be interrupted by tumefaction of the tissues embracing the duct. It is certain that many cases of so-called catarrhal jaundice are to be explained in this manner.

Owing to this inconstant relation of the choledochus to the pancreas, it is apparent also that a high degree of inflammation or sclerosis of the pancreas may be consistent with the absence of jaundice. All the cases of jaundice with pancreatitis are not to be explained on mechanical grounds, but a certain percentage are doubtless due to disease of the bile passages themselves or to extension of inflammation from a catarrhal duodenum. The jaundice may come on painlessly, as occurred in four cases. It may also be continuous, as in five cases. The surgical importance of these facts cannot be overestimated. When associated with rapid wasting and loss of strength, which may occur in this disease, the clinical simulation of malignant disease of the head of the pancreas is complete and patients have repeatedly been denied operation under the impression that it was useless; a fatal blunder. Here also I may say that the mistake is not always rectified by simple exploratory operation, for the hardened nodular pancreas of advanced inflammation may so resemble carcinoma as to defy differentiation by direct inspection and palpation. Even the glands of the neighborhood may be greatly swollen as though by extensive metastasis. Robson, Moynihan, Mayo, and other leaders in upper abdominal surgery, have more than once mistaken inflammation for carcinoma, and I own to the same error on a number of occasions. In one case not only was jaundice and wasting present, but there was marked ascites due probably to the biliary cirrhosis or to pressure of the thickened head of the pancreas on the inferior vena cava. The patient made a good recovery after operation.

I have in mind now a physician of this community on whom I operated within the past year and closed with a hopeless prognosis of pancreatic carcinoma. The subsequent course has led me to believe that in this case I was deceived.

More often jaundice is preceded by pain as in gall-stone colic, though, as previously stated, the pain is apt to be less severe and not colicky in character. In the more acute forms of pancreatitis it is, of course, a well-known fact that the pain is of such agonizing severity as hardly to be compared with that of any other disease. Such an exacerbation may occur at any time in the course of chronic pancreatitis.

The combination of intermittent jaundice, pain and febrile attacks may also be perfectly characteristic of Charcot's hepatic intermittent fever. I have diagnosed stone in the common duct in such cases and when considering them later have been unable to find any reason why I should not do so again. I am not sure that a stone may not have been present and escaped shortly before operation, and I have referred to one instance above in which such was known to have been the case.

The degree of jaundice may vary from the slightest tinge to the "black jaundice" of the older writers, which was supposed to be diagnostic of malignant disease. Sialorrhea, though often mentioned, I have not observed.

General symptoms are usually well marked. The existence of chronic pancreatitis, to a degree that pancreatic function is seriously disturbed, is always associated with a loss of weight. This is due to several causes: First, to a restriction of the diet voluntarily or by advice of physician in the effort to control the symptoms of indigestion. At times impairment of the appetite is responsible for decreased intake of food, though loss of appetite is by no means a constant accompaniment of pancreatitis. In this series it is mentioned seven times. There is also no disgust for meat. The persistence of the appetite is a valuable point of difference from carcinoma. Second, it is due to malassimilation of the imperfectly digested food. Third, in the cases in which jaundice is present, to the influence of the biliary intoxication: and finally, in a few cases, to the absorption of the products of bacterial activity.

Loss of weight was noted in twenty-one cases. The state of nutrition at the time of operation was, in six cases, obese, in ten good, and in thirteen poor. Loss of strength follows loss in weight, and was complained of in ten instances. I have already referred to the rapid loss of weight and strength which may take place in some instances, particularly when jaundice is a marked symptom. The cachexia may be as rapid and extreme as in malignant disease. In the usual case such marked wasting does not occur.

In most instances fever was known to have been present and in five a history of chills and sweating was obtained. In one the temperature was slightly subnormal. In eleven at the time of operation it was between 98 and 99 F., in thirteen between 99 and 100 F., and in four between 102 and 103 F. Fever is not such a prominent symptom in the prolonged course of chronic pancreatitis as most figures would seem to indicate. As a rule the temperature is normal. Fever is present only during exacerbations. Between the attacks there may be non-committal indigestion. In thirteen cases of this series there was indigestion between attacks. The longest duration of the disease as estimated by symptoms was seventeen years; the shortest eleven days. Ten had had frequent attacks of varying severity.

The bowels, as a rule, are constipated. Nineteen patients suffered with chronic constipation, and in thirteen cases constipation was a feature of the attacks. In only five was there a history of diarrhea.

From this it will be seen that caution must be used in employing as an aid to diagnosis the classical description of "frequent bulky motions, pale in color, offensive and obviously greasy." As stated by Robson and Cammidge, such stools are present only in advanced conditions.

The physical examination rarely affords much positive information. It is of more value in excluding other abdominal conditions. During exacerbations there may be epigastric tenderness and rigidity. When this is true it is almost impossible to detect anything in the nature of a mass. During the intervals, in patients with thin flaccid abdominal walls, it is sometimes possible to palpate the swollen head of the pancreas. In three cases of this series a rather indefinable mass could be felt. More often a considerable degree of pancreatic swelling and sclerosis will defy appreciation through the body wall and overlying viscera. In the majority of instances the pancreas is well covered by the adjacent organs. Körte, who examined thirty cadavers with reference to this point, found that in twenty the pancreas was completely covered, while in ten some part of the gland was covered only by omentum. In six instances there was ptosis of the colon, with exposure of a portion of the head of the pancreas between the colon and liver. In two bodies it was exposed in the median cleft of the liver, and in two, which were the seat of marked gastroptosis, the pancreas could be palpated directly beneath the gastrohepatic omentum. In palpating through the body wall, however, these slight exposures of pancreatic tissue are rarely sufficient to give a definite sense of mass even to the tactus eruditus.

As most of these patients were operated on during or just after some exacerbation of symptoms there was a degree of tenderness present in most of them. In eight no tenderness was elicited. In the remainder tenderness was found below the right costal margin in twenty; beneath the left in three; in the mid-epigastrium in eleven; over Mayo-Robson's point in three, and in one more severe case it was general. Rigidity was observed in the right hypochondrium in nine cases and over the epigastrium in three. There was moderate distention in six cases.

Enlargement of the gall-bladder has been observed in a number of cases, but it was not felt prior to operation in this series. The liver, however, was noted as enlarged nine times.

The general examination at times may reveal loss of weight and jaundice as above stated.

The blood frequently shows a secondary anemia which is seldom grave. In about one-half of my cases the hemoglobin was below eighty and the erythrocytes below 4,000,000 per c.c. A moderate leukocytosis was present in a few of the more acute exacerbations. Generally the numerical ratio of the leukocytes was unaltered.

Now as to the various tests used to determine the functional activity of the pancreas and upper digestive tract: A gastric analysis was made in twenty-four cases. In two-thirds of these there was subacidity both of free hydrochloric acid and total acids. In no case was there a marked hyperacidity. In other respects the analysis was not abnormal. The great number of conditions associated with subacidity of the gastric contents deprives this observation of any diagnostic value.

Somewhat more information can be derived from examination of the stools. In ten instances they were clay-colored. It is well known that this characteristic does not depend so much on the absence of bile as on the presence of an excess of fatty acids or fat itself. The tests for stercobilin were positive in all of these instances, showing that bile was entering the intestinal tract. This is important and leads to the deduction that since the liver is functionating, the failure to digest the fats must be due to deficiency of the pancreas. An excess of neutral fat so marked as to be visible to the naked eye, i. e., steatorrhea, was present in only six cases, and an excess of soaps was found in five cases. In pancreatic disease the total amount of unabsorbed fat may reach 50 to 60 per cent. in cases of chronic pancreatitis, and even 75 to 90 per cent. in cases of malignant disease (Robson and Cammidge). Carnot says that after suppression of the bile alone, the feces contain 60 per cent. of fat; after suppression of the pancreatic secretion, 70 per cent. of fat; and after suppression of both bile and pancreatic juice, they contain 90 per cent. of fat. In health, according to Müller, "the unabsorbed fecal fats consist of approximately 20 to 30 per cent. of neutral fat and from 70 to 80 per cent. of split fat, which is partly fatty acids and partly soaps." R. Gaultier has shown that in cases of suppression of the bile there are found in the feces from 35 to 45 per cent. of the ingested fats; 63 per cent. of this exists as neutral fats, and 35 to 40 per cent. as split fats (21 per cent. as fatty acids, and 12 per cent. as soaps). He has found that, in cases of suppression of the pancreatic functions, 80 per cent. of the fecal fat is in the form of neutral fats, and only about 15 per cent. as split fats (10 per cent. as fatty acids, and 5 per cent. as soaps); and if both biliary and pancreatic secretions are absent, 90 per cent. of the ingested fat is recovered from the feces, of which 90 per cent. is in the form of neutral fats, and 11 per cent. as split fats (10 per cent. as fatty acids, and 1 per cent. as soaps). Müller found that in cases of pancreatic disease, even though the total percentage of fecal fat might not be increased above the normal, yet that the proportion of split fat is always decreased (averaging about 40 per cent. of the total fat), showing decrease in the digestive power for fatty food. It has been asserted by Katz that diminution of the split fat below 70 per cent. of the total fecal fat invariably signifies disease of the pancreas, except in nursing infants and patients with profuse diarrhea. It remains to be seen whether the quantitative relations of the fat and its derivatives in the feces will be of any great assistance. Since we have found practically normal stools in cases which presented very definite chronic pancreatitis, it is evident that a negative finding is not conclusive. Positive results, on the contrary, must be regarded as very suggestive, and the examination of the feces for its fat and bile contents constitutes a very important element in the diagnosis. Excess of muscle fibers could be found in those instances of palpably deficient pancreatic function, but was not a characteristic of this series. The digestion of protein material appears to be less helpful than fat digestion. Fitz has pointed out that the condition occurs "only when there is extreme diminution of the pancreatic juice, and is significant only when gastric digestion is normal, when the diet contains no excess of meat, and when there is no diarrhea" (Opie). In fact, the majority of stools showed nothing by which a presumptive diagnosis of lack of pancreatic secretion could be assumed. As Opie remarks, "in most instances a considerable part of the parenchyma is undestroyed, and is capable of performing, in part, at least, the functions of the gland." The characteristic stool of pancreatitis, when present, is of great value in the diagnosis, but when absent does not negative the existence of pancreatitis.

The examination of the urine has been given special prominence by the reaction of Cammidge, which has received the endorsement of such able surgeons as Robson and Moynihan. As is well known, this reaction consists in the demonstration in the urine, when treated by a rather complex chemical procedure, of certain crystals of a definite morphology and certain solubility characteristics, but of unknown composition, though it is thought to be a derivative of a pentose, probably an osazone.

A positive reaction is said to indicate the presence of simple pancreatitis. It has been found in a percentage of cases of carcinoma of the pancreas, which is explained by the originators as due to the presence of an inflammatory zone about the neoplasm. The improved or "C" reaction is now used to the exclusion of the old "A" and "B" methods.

The table published in Robson and Cammidge's recent book gives the reaction credit for accuracy rarely attained by any other laboratory method.

In sixty-seven cases of pancreatitis it was positive in every case. In sixteen cases of carcinoma of the pancreas it was found in four (25 per cent.). On the other hand, in fifty normal cases used as controls it was uniformly negative, while in 117 associated cases, in which there was no pancreatitis, it was positive only four times. This is a remarkable showing, and if obtained by others would almost obviate the necessity of obtaining a history, a physical examination or, indeed, seeing the patient at all. We have paid special attention to the Cammidge reaction in the German Hospital. Dr. Kinney has been especially interested in it, and his report of the first 154 "C" reactions appeared in the *American Journal of the Medical Sciences* (December, 1910). Following the cases included in his report we have had 197 additional cases, making, in all, 351, which constitutes a very fair experience by which to judge the merit of the test. While I am free to admit that the originator of the reaction can probably perform it best, yet his very detailed directions have been most carefully followed, and our results must certainly approximate the best obtainable under similar circumstances.

Of nineteen cases, in which the test was made in the present series, it was positive in four and negative in fifteen. This is a scarcely higher percentage of positives than we obtained in sixty cases in which the pancreas appeared to me to be normal to direct palpation at the time of operation. Ten of these sixty cases gave a positive Cammidge reaction. One-fifth positive in pancreatitis, as compared with one-sixth positive when no pancreatitis existed, does not inspire faith in the reaction. In fifty-five cases of chronic pancreatitis, confirmed at operation, some of which were complicated by other upper abdominal disease, there were eighteen positives (32 per cent.), a slightly better showing. Two acute cases were both positive. One case of pancreatic cyst was negative; one of pancreatic fistula was positive, and of eight cases of carcinoma of the pancreas, one-half gave the reaction. Roughly speaking, in all my cases in which the condition of the pancreas was determined accurately at the time of operation, this supposedly specific pancreatic reaction was obtained only about two and a half times as frequently when the pancreas was affected as when it was not. While this speaks for a degree of dependence on pancreatic disease, it does not, to my mind, indicate that that relation is by any means so intimate and constant as we had been led to hope.

The urine in suspected pancreatitis should be carefully tested for bile and sugar. Two cases in this series showed glycosuria. Sugar may appear in the urine during an exacerbation and clear up on subsidence of the inflammation. This is a threat of oncoming diabetes and should not be overlooked.

I have not used the Loew pupillary reaction, which consists in a dilatation of the pupil on instillation of epinephrin into the conjunctival sac. This is supposed to be due to some interrelation between the produce of the suprarenal capsule and the hypothetical internal secretion of the pancreas. Clinical reports do not accord it much value.

Nor have I had experience with the various methods of obtaining duodenal juice, either through the stomach or in the feces, and testing it for the presence of pancreatic ferments. It seems to me that as these ferments act in incredibly small quantities, so long as there is any pancreatic tissue functionating we would expect to get the reaction due to their presence. When they are absent the condition would probably be far advanced and capable of detection by simpler means.

The chief tests of this sort are as follows: Schmidt's test depends on passing a small piece of beef, enclosed in a silk bag, through the intestinal tract, and observing whether the muscles of the fibers showed digestion. Sailer quotes the work of Steele, who came to the conclusion that this was valueless.

Müller's test aims to demonstrate the absence or presence of a proteolytic enzyme in the feces, by observing whether digestion of blood-serum will take place when drops of fecal material, appropriately prepared, are placed on its surface.

Sahli's desmoid test consists in administering capsules, hardened in formaldehyd resistant to the gastric juice, but soluble in pancreatic secretion. In the capsule is placed a substance capable of rapid absorption and excretion in the urine, thus determining whether solution has been effected.

Solomon attaches great importance to the amount of lecithin in the feces, which is said to be increased in pancreatitis.

Fedeli and Romanelli have devised a test to measure the activity of carbohydrate digestion.

While it is too early to say that these tests have no value it is not likely that they will put an end to our difficulties in the diagnosis of chronic pancreatitis.

The appetite is usually fair or quite good. If nausea or vomiting occurs without severe pain, and if remittent jaundice comes on with distress, but without characteristic gall-stone seizures, the presumption is strengthened.

If the pancreas may be felt enlarged and tender, or the feces present the characteristic stool, the diagnosis can be made with a fair degree of certainty. It is often necessary to observe these patients over a considerable period of time to come to a definite conclusion. As this early non-characteristic stage is very like the non-characteristic beginnings of some forms of malignant disease in the upper abdomen, it is necessary to be guarded in the prognosis and the decision to delay operative treatment.

The chief conditions likely to be mistaken for pancreatitis are cancer of the pancreas, of the common bile-duct or the liver, gall-stones in the common duct, chronic cholangitis without stones, and chronic appendicitis of the type manifesting itself chiefly or solely by upper abdominal symptoms.

The treatment of chronic pancreatitis begins with the amelioration of the predisposing cause or causes, if they can be determined. When gastroduodenal catarrh is present as a result of vicious habits of eating or drinking, a reform must be instituted in these respects. When it is associated with disease of the biliary passages, treatment should be directed toward that condition. Wohlgemuth has shown that the pancreas responds actively to a carbohydrate diet, and that if rest for the inflamed gland is desired it is necessary to be sparing in articles of that nature. Carnot is enthusiastic in advocacy of supplying the missing elements of digestion by administration of a preparation of the gland. Sailer also reports good results in two cases treated on this basis. While such measures may suffice for mild cases, or at times for more severe forms, there are others that go from bad to worse on careful medical treatment. Continued loss of weight, persistence of indigestion, recurring exacerbations, jaundice or a lowered tolerance for carbohydrates as shown by transient glycosuria should cause the physician to advise operation. Epecially binding is this obligation if there be associated disease of the biliary tract.

In the surgical treatment of chronic pancreatitis, Mayo Robson occupies the same position as Fitz does to the development of our knowledge of the disease. He was the pioneer in showing that free drainage of the biliary tract, and through this outlet, drainage also of the pancreatic ducts, would in many instances enable the pancreas to cast off the infection and resume its normal function. This is, in a nutshell, the principle of the treatment, and though it may seem roundabout, its efficacy has now been demonstrated too often to admit of a question. The easiest and most advantageous method of providing drainage is by a cholecystostomy. If for any reason this is impracticable, drainage of the common duct should be done. At times when the closure of the common duct is complete and likely to be lasting, a cholecystenterostomy may be best, but as a general rule external drainage permits subsidence of the swelling of the pancreas and a reestablishment of the functions of the ducts. Drainage should be maintained for three or four weeks at least. It is difficult to keep the fistula from closing too soon, and in cases of marked pancreatic disease it is best to make a cholecystduodenostomy. Just how long this opening will remain patulous is a question, for I have reoperated in cases in which this operation had been performed, and have found the opening closed. It should not be forgotten, also, that cholecystduodenostomy is an operation of greater magnitude and slightly higher mortality than simple cholecystostomy.

The surgeon to-day makes the same plea for chronic pancreatitis as he made twenty years ago for appendicitis. Send patients early before complications create a mortality.

1634 Walnut Street.

A Funny Proposition.—The *Boston Transcript* makes the very pertinent remark that man is a funny proposition because, when he reads a medical book, he fancies he has every disease described; but when he reads the work of a moralist, all the faults that are pointed out he sees, not in himself, but in his neighbor.

INTESTINAL BACTERIOLOGY: A SUMMARY*

ARTHUR I. KENDALL, Ph.D.

BOSTON

It is the purpose of this paper to discuss certain factors of fundamental importance in determining the nature and extent of bacterial activity in the intestinal canal; to explain what these factors are and how they are arrived at; to indicate their significance and to point out how they may be applied practically in intestinal therapy. The results of which this paper is a summary were obtained chiefly by feeding animals (cats and monkeys) on diets consisting alternately of protein and carbohydrate. The alternations in diet were made biweekly. The object of these experiments was to determine the influence of diet on the character of the intestinal flora.

From the point of view of bacterial activity within it, the alimentary canal must be regarded as a wonderfully perfect incubator and culture medium combined—an incubator in which the range of reaction and diversity of foodstuffs is so great that practically all organisms capable of developing at the body temperature of the host can conceivably find some place suited for their development. It is necessary to keep this conception in mind, since the essential feature of the investigations about to be outlined consists of changing the food of the bacteria growing in this intestinal incubator in a perfectly definite manner and sequence, and observing the effects by studying the readjustments of the intestinal flora to meet the new conditions established as the food of the host changes.

The problem is one which must be approached from the dynamic rather than from the cultural standpoint, and the key to its solution must come from the biochemistry of the bacteria concerned in the process rather than from their cultural characteristics. As Dr. Theobald Smith has clearly and tersely expressed it: "It is what bacteria do, rather than what they are, that commands our attention, since our interest centers in the host rather than the parasite."

Before discussing the results in detail, it will be necessary to call attention to several features of the problem which are better mentioned here than later on:

1. In these experiments, the diet of the host was sharply limited to two classes of foodstuffs, and as a working hypothesis, it is fair to assume that the bacterial response to these dietary alternations would consist largely of alternations between proteolytic and fermentative types of organisms, respectively.

2. The intestinal flora can respond to these changes in diet in two ways: (a) the flora may become dominantly proteolytic, then fermentative, as the diet is changed, and (b) in addition to the alternations in bacterial types, certain organisms can actually change their metabolism to accommodate themselves now to a protein, now to a carbohydrate regimen.

3. The products of digestion of protein in the alimentary tract are far more numerous and varied in composition than are those of carbohydrate; consequently one would expect *a priori* that the protein flora would be more heterogeneous than that developed on a carbohydrate regimen. That such is the case is well illustrated by comparing the fecal floras of adults and nurslings. In the former, on a varied regimen, containing much protein, the flora is very heterogeneous, while that of the latter, on a monotonous diet in which protein is in the minority, and carbohydrate a prominent feature, the flora is relatively homogeneous.

The method employed in this work consisted essentially of inoculating the mixed fecal flora into suitable media and studying the resulting reactions in them. From time to time cultures of the prominent bacteria discernible in the fecal flora were isolated and compared with those growing in the cultures; by so doing it was possible to determine the suitability of these media for the purpose they were to fulfil, and to form a judgment of the character of the organisms which composed the fecal flora as well.

The media finally selected were gelatin (sugar-free), acetic acid-dextrose broth (N/5 acetic acid in 2 per cent. dextrose broth), dextrose, lactose and saccharose fermentation media and milk fermentation tubes (Smith). Each of these media presents certain specific advantages in addition to its general utility as a food for bacteria. Much valuable information was obtained from the study of Gram-stained preparations of the feces, fermentation tube sediments and from the growths in other media. It was possible to form a judgment of the suitability of the various media by comparing the prominent organisms in the feces and those in the media themselves.

These media could be divided, according to the kinds of bacteria growing in them into three groups:

Group 1: Gelatin: particularly adapted for the proteolytic forms.

Group 2: Acid dextrose broth: specific for certain fermentative organisms, chiefly of the *B. acidophilus* type.

Group 3: Fermentation media and milk: practically all the dominant bacteria represented in the feces grew well in these media, and consequently they were, in a sense, battle-fields in which the various types of organisms struggled for supremacy. The manner in which the mixed fecal flora acted in the media of Group 3 furnished a valuable clue to the dominant type of bacterial activity in the intestinal tract.

Turning now to the phenomena exhibited by the various bacteria of the alimentary tract as the diet was changed, it was found that as the protein flora became dominant, the Gram-stained fields prepared from the freshly passed feces contained many large and medium sized Gram-positive rods with rounded ends. Gram-negative forms similar to colon bacilli morphologically, and a few coccal forms also appeared. In addition, there were frequently moderate numbers of Gram-negative, thin rods.

Inoculated into gelatin, the mixed intestinal flora caused a decided liquefaction, which commenced as a rule within eighteen hours and continued until practically the whole medium was peptonized. In sugar broths there was a considerable volume of gas formed within eighteen hours, not infrequently 100 per cent. of the closed arm. The Gram-stained sediments from these fermentation tubes contained both the short, Gram-negative bacilli morphologically like *B. coli* and *B. proteus*, and also larger, longer and thicker Gram-positive rods which were morphologically similar to the so-called gas bacillus (*Bact. welchii*), but which were in reality organisms belonging to the *subtilis* group. It is noteworthy that the gas bacillus did not play any prominent part in the formation of gas in these media.

Acid dextrose broth remained unchanged, and there was very little growth in it.

Milk was vigorously attacked; the casein peptonized to a very considerable degree, and, usually from 50 to 80 per cent. of gas was produced, all within eighteen hours' incubation at body temperature. This rapid peptonization and gas formation in milk is a striking phenomenon, and deserves comment. The same action can frequently be brought about, although much more slowly, by inoculating milk contained in fermentation tubes with a culture of an organism belonging to the *subtilis* group, then, after peptonization has commenced, reinfect the medium with a pure culture of *B. coli* or *B. proteus*. Under these conditions the peptonization continues, and in addition, there is a voluminous liberation of gas. It is absolutely essential for the success of the experiment that the order mentioned be observed. If the colon bacillus is inoculated first, and then, after a preliminary incubation, the subtiloid organism be introduced, the phenomena mentioned will, as a rule, not take place. This is a true instance of symbiotic activity which is not confined to bacteria derived from the intestinal tract. I have encountered it in bacteria from meat and other albuminous products which have commenced to decompose. It should be stated that the combined activity of these two organisms is greater than the sum of their separate activities. The explanation that seems most thoroughly to explain all the facts is that the subtiloid bacilli first act, and, in the case of the milk, peptonize the casein, but do not attack the lactose; since this sugar is unfermentable by most subtiloid organisms. The solution of the casein in some manner makes the lactose more accessible to the action of the colon bacillus, and the alkaline reaction produced by the subtiloid bacillus tends to neutralize to a certain extent the acid produced by the fermentation of the lactose by the colon bacillus, so that the process can go much further than would be the case with the colon bacillus alone. On the other hand, the production of acid by the colon bacillus neutralizes the alkali produced by the subtiloid organism, thus preventing a too alkaline reaction, which would inhibit the activity of the subtiloid bacillus. In dextrose and lactose fermentation media, again, one sees the same phenomenon of unusual gas production when the same organisms are growing symbiotically. The explanation appears to be the same in these instances as well as in the milk.

---

* From the Department of Preventive Medicine and Hygiene, Harvard Medical School.

The organisms dominant on a protein diet, then, are of two principal types: liquefying and aerogenic bacilli, respectively. Of the former, the subtiloid bacilli appear to play the most prominent rôle, while *B. coli* and the various forms of *B. proteus* are the most commonly encountered aerogens. Anaerobes do not play an essential part in these processes.

A change in diet from protein to carbohydrate was associated with perfectly definite changes in the character of the fecal flora. The fecal Gram-stained fields became strongly Gram-positive in place of the more or less equal distribution of Gram-positive and Gram-negative organisms. The organisms were longer, more slender, and frequently were seen to be slightly curved. The flora was also much more homogeneous in appearance.

In gelatin there was very little growth when the carbohydrate flora became fully established, and the organisms which did develop were vestiges of the protein flora.

Acid dextrose broth on the contrary contained a good growth which consisted almost wholly of the rather long, slender curved organisms discernible in the Gram-stained fields of the carbohydrate fecal flora. These organisms were of the *B. acidophilus* type, and in consequence of the acidity of the medium (N/5 acetic acid) were in practically pure culture.

The sugar broths (dextrose, lactose and saccharose) and milk fermentation tubes were less visibly changed with the carbohydrate flora; the gas volume was very much diminished both in the sugar broths and milk, and the actual amounts of growth were also less than was the case when protein feces were inoculated. As a rule less than 10 per cent. of gas was produced in the sugar broths, the turbidity in the closed arms of the fermentation tubes was less marked, and the sediments showed both the long, thin Gram-positive organisms noted above (*B. acidophilus*) and similar, slender organisms, also Gram-positive with bifid ends. The latter organisms were found to be *B. bifidus*, organisms very common in the fecal flora of normal nurslings.

In milk there was no gas formation, and no peptonization. The milk, however, was firmly coagulated.

The significance of these changes appears to be explained by the fact that the fermentative organisms of the *acidophilus* and *bifidus* types produce acid rapidly from the time they are inoculated into the various media in which they thrive, and that this acid-production is so rapid and so intense that even the rapidly growing colon and subtiloid bacilli cannot develop in its presence. This is true, of course, only in those media containing fermentable sugar. In gelatin, which contains no sugar, or in plain, sugar-free broth, the fermentative organisms of the *acidophilus* and *bifidus* types will not grow, and one finds in such media the typical proteolytic flora—*B. coli* and *subtilis*.

To recapitulate: It will be seen that in experimental animals, alternations in diet between protein and carbohydrate are associated with rather definite changes in the character of the intestinal floras of these animals. These bacterial changes are demonstrable both by staining reactions and by the changes produced when the mixed floras are inoculated into media. These changes consist essentially of alternations between proteolytic and gas-forming bacteria on a protein diet, and acid-forming bacteria on a carbohydrate regimen. The absence of carbohydrate prevents the development of the acid-forming bacteria on a protein diet, and the excessive amounts of acid produced by the fermentation of sugar inhibits the growth of the proteolytic and aerogenic forms on the carbohydrate regimen.

THERAPEUTIC APPLICATION OF FINDINGS

Turning now to the practical application of these results to intestinal therapy, we may conveniently consider them in two groups:

1. Those cases in which there is an overgrowth of undesirable forms of the bacteria more or less commonly present in the intestinal tract. These organisms do not, as a rule, bring about appreciable lesions of the intestinal mucosa. The activity of these bacteria is limited to their more or less unrestrained growth in the intestinal contents, and their harmful effects are attributable to the absorption from the intestinal tract by the host of their products of metabolism. Some of these products have been shown experimentally to be actually harmful. These endogenous infections may cause diarrhea, as well as that rather indefinite chain of symptoms known as auto-intoxication of intestinal origin.

2. True exogenous infections, in which foreign bacteria such as the typhoid, dysentery and cholera bacilli gain and maintain a foothold in the alimentary tract. These organisms are able to penetrate the intestinal mucosa.

The treatment of these conditions, from the bacterial standpoint, involves the principles elucidated above. It was stated in the preceding paragraphs that not only do the *types* of bacteria change with a change of diet on the part of the host, but also that certain bacteria have the property within limits of accommodating their metabolism now to a protein; now to a carbohydrate regimen. These latter organisms, then, are facultative in their metabolism. This change in metabolism to meet dietary requirements is a very fundamental and important characteristic of many bacteria, and inasmuch as it plays a prominent rôle in the problems of intestinal therapy which are concerned with the activity of bacteria, it will be discussed in some detail.

A few examples will first be cited to indicate the effect which this accommodation of metabolism has on the host in which such bacteria may be living.

Dr. Theobald Smith has shown, in his classical researches on the production of diphtheria toxin in broth, that the presence or absence of fermentable sugar plays an important part. If utilizable carbohydrate is present in the medium in which the bacilli are growing, the organisms will attack the sugar in preference to the protein; if there is an excess of sugar, so that the bacilli form enough acid to prevent further growth before it is exhausted, very little toxin, comparatively is produced. If there is a lesser amount of sugar (0.2 per cent. or less), merely enough to cause the bacilli to grow well, this sugar is soon used up, and then the bacteria attack the protein vigorously and there is a simultaneous increase in the toxin production.

(In this discussion, no attempt is made to explain the origin or composition of the toxin other than to call attention to the fact that it is formed under the conditions stated in media containing protein, or protein decomposition products, and that the presence of more than minimal amounts of sugar in these media is sufficient to seriously inhibit its formation. The fact that toxin is apparently formed in appreciable amounts from such simple organic compounds as salts of aspartic acid has nothing to do with the problem under discussion, although it is very probable that even in these so-called synthetic media, the presence of sugar would act in precisely the same manner as it does in the more complex proteins.)

A certain minimal amount of sugar appears to be essential for the formation of a potent toxin, and Dr. Smith has suggested that one, or both, of two factors may explain this phenomenon. Either this small amount of sugar is an essential component of the food of the bacteria, or the slight amount of acid formed by the fermentation of this sugar prevents the accumulation of too much alkali until the toxin formation has progressed to a very considerable degree. It is not improbable that both factors are concerned in the process.

According to unpublished investigations made by Dr. Smith, the same phenomenon is exhibited by the gas bacillus (*Bact. welchii*). This organism, so Dr. Smith tells me, produces a toxic substance when it is grown in fermented (sugar-free) broth containing sterile tissue, but this toxic substance is not formed if the same organisms are grown in unfermented broth, with tissue.

Many other organisms act in precisely the same manner when they are placed in media containing sugar; the presence of the sugar appears to prevent the breakdown of protein, at least in any considerable quantities. Attention was called in a preceding paragraph to the fact that there was in the intestinal tracts of mammals and man a group of facultative bacteria which could accommodate their metabolism to either a protein or a carbohydrate regimen. These organisms act in the same general manner as the diphtheria, tetanus and gas bacillus under similar conditions.

Bacillus coli is a well-known example of this group, and inasmuch as it is an organism of great importance in the intestinal tract, it will serve admirably for an example. If this organism is grown in broth containing an excess of utilizable sugar on the one hand, and in broth of precisely the same composition and reaction, but without the sugar on the other, it will be found that the chemical products formed in the two media will be widely different in composition. In dextrose broth, for example, the odor after an incubation of a week will be agreeable, the reaction acid, and in addition to the gaseous products CO_2 and H_2, lactic, and smaller amounts of succinic and acetic acids will be found. It will be observed that products of protein decomposition are practically absent, on the other hand. This growth is therefore a fermentative process and not a proteolysis; merely enough protein has been metabolized to meet the nitrogen requirements of the bacilli.

In the broth containing no sugar, on the contrary, but of otherwise the same composition (plain nutrient broth), the odor will be found to be disagreeable, the reaction strongly alkaline and in addition, indol, skatol, aromatic oxyacids and other products of protein putrefaction will be present in considerable amounts. This is therefore a typical putrefaction.

The organisms mentioned above, then, diphtheria, tetanus, gas and colon bacilli, all react in a perfectly definite manner when grown in media with and without fermentable carbohydrate. If carbohydrate is present, these organisms form acid products which are non-toxic, while they attack protein vigorously in the absence of sugar, elaborating products which are frequently more or less harmful to their host. (It should be stated parenthetically that by "attacking protein," as used in this connection, protein of various degrees of degradation from native proteins is meant.)

Two important and general properties of bacterial activity are illustrated by these experiments:

1. Fermentation takes precedence over putrefaction, that is, carbohydrate shields or spares protein from bacterial attack. The same generality holds in the metabolism of the human body; carbohydrate spares protein.

2. Toxic substances are not formed to any extent in media containing more than minimal amounts of utilizable carbohydrate, so long as there is enough carbohydrate for the bacteria to act on.

When we remember that bacterial toxins are, so far as we know at present, associated with the breakdown of protein, the significance of this shielding action of carbohydrate for protein becomes apparent.

In those cases referred to above as endogenous infections, that is, in which there is an overgrowth of bacteria of intestinal origin, the most noticeable, or at least most common, pathologic result is the slow absorption of putrefactive products, which not infrequently are the results of a too liberal protein diet.

Metchnikoff has recognized this condition and his lactic acid therapy is designed to correct the trouble. His treatment consists essentially in cutting down the protein of the diet, pushing up the sugar, and administering lactic acid bacilli by mouth. He explained the beneficial results which frequently attended this treatment by the antagonism of his lactic acid bacteria to the putrefactive organisms in the intestinal tract. While his lactic acid bacilli do, as a matter of fact, act in a salutary manner, it must be remembered that there are also present in the intestinal tracts of most individuals normal lactic acid bacilli which also produce lactic acid. These latter organisms appear to thrive best in the large intestine, while the artificial cultures seem to find conditions most favorable for their growth in the small intestine. Hence, the normal lactic acid bacilli, fermenting the sugar which is intentionally added to the diet of the host, antagonize the putrefactive bacteria on their own grounds. Not only do the normal lactic acid bacilli proliferate under these conditions, but the organisms which are producing the bulk of the putrefactive products, at least indol and skatol, change their metabolism under the new conditions, and become fermentative instead of putrefactive in character. The indol and skatol are no longer formed under these conditions, and the condition of the patient appears to be improved. The colon and proteus bacilli, which are strong indol-formers, in other words, produce acids instead of proteolytic products so long as sugar is available for their use.

The same principle of changing the metabolism of bacteria may be made use of in the second group of intestinal infections, those of exogenous origin. The best-known examples of such infections are those of typhoid, cholera and dysentery. The latter only will be discussed, because the attempt has been made to utilize the principles outlined above in the treatment of this disease in infants. The Shiga type of *B. dysenteriæ* produces a powerful extracellular toxin, and the work of recent observers would indicate that it is formed only in broth having a strongly alkaline reaction. From what has gone before, it is obvious that this condition of a strongly alkaline reaction is realized only in the absence of fermentable sugar. It is equally true that the Shiga bacillus ferments dextrose, producing acid. It follows, therefore, that if this organism is fermenting dextrose it is not producing toxin, if our supposition is correct. The Flexner type of *B. dysenteriæ* agrees with the statements about the Shiga bacillus made above, except that this form does not produce an extracellular toxin. It does, however, elaborate an intracellular toxin apparently.

The intestinal flora of babies suffering from bacillary dysentery consists essentially of three organisms: *B. dysenteriæ* [Shiga, Flexner, or both], *B. coli*, and the streptococcus.

As a routine treatment, such babies are starved, and this starvation, together with the severe diarrhea, which is a feature of this disease, results in a very thorough cleaning out of the alimentary canal so far as food of any kind is concerned. This dysenteric flora, then, is living on the intestinal secretions in the absence of sugar (the sugar of the body is used up quickly, and the body then draws on its nitrogen to keep up the vital functions), and it is essentially putrefactive in nature. The dysentery bacilli are elaborating toxin, while the colon bacilli are forming putrefaction products, both of which must be harmful to the child. The colon bacillus aids the dysentery bacillus, and the host has to detoxicate such putrefactive products as are absorbed by the alimentary canal in the liver, and excrete them through the kidneys. This throws an additional strain on an already weakened organism.

The principle involved in the treatment of bacillary dysentery, from the point of view of the bacteria concerned in the morbid process, is to feed carbohydrate. This carbohydrate is intended primarily to change the metabolism of the organisms in the lumen of the intestinal canal from proteolytic to fermentative bacteria. These bacteria, therefore, so long as there is sugar present which they can utilize, no longer produce toxins and putrefactive products from the protein of the intestinal contents, but acids instead. The patient is at the same time obtaining a readily utilizable food with a minimal expenditure of digestive energy. Another advantage gained by this procedure is the readiness with which the baby takes the requisite amount of water. Experience has shown that it is very difficult to make infants take water, but the addition of the sugar makes it more palatable. This method of introducing fluid does away with the disagreeable necessity for saline infusions which are often a source of trouble.

It is not a matter of indifference which sugar is fed to these patients. Lactose appears to be the most advantageous for several reasons. In the first place, it is a sugar peculiar to mammals, and not many bacteria other than those normally present in the alimentary canal can utilize it. Consequently, if the digestion of the patient is weakened to such an extent that it can not even hydrolyze lactose, there is no great harm done because the exogenous bacteria cannot use the lactose as such. Again, lactose is physiologically the most easily assimilable carbohydrate.

If, then, lactose is fed to dysentery babies by mouth in small, often repeated doses, the bacterial changes following its administration are as follows: The colon bacilli and other lactose-fermenting organisms of the intestinal tract attack the sugar in preference to the nitrogenous substances, forming acids in place of putrefactive products. Lactic acid predominates among these acids, and this acid is apparently inimical to the development of the dysentery bacillus. The patient benefits in two ways from the change in metabolism of the colon bacillus—there is a diminished formation of putrefactive products, and in addition those dysentery bacilli in the lumen of the intestine are exposed to the lactic acid generated by the colon bacilli. Usually there are a few of the normal intestinal lactic acid bacilli left in the alimentary canal, and these too begin to proliferate and to form lactic acid; this increment in acid formation acts even more energetically in opposition to the dysentery bacilli.

Under these conditions the streptococcus tends to disappear, and this is a point of considerable importance, since the streptococcus frequently appears as the terminal infection in dysentery cases. The cause for this disappearance is at present unknown to me. It is a curious fact that one may recover cultures of these or similar cocci by growing the fecal mass in strongly alkaline broth (N/5 Na$_2$CO$_3$).

If the digestion of the patient is still active enough to break down the lactose, the dysentery bacilli themselves will become acid-formers instead of toxin-producers, because these bacilli can attack dextrose, which is one of the hydrolytic products of lactose. This applies principally to those bacilli which are found in the lumen of the alimentary canal; those in the mucosa would at first sight seem inaccessible, but the stream of sugar which is absorbed by the host passes through the mucosa, and in addition it is possible to restore the normal sugar content of the blood by transfusing dextrose. The sugar is carried to all parts of the body, and it is not at all impossible that some of it may even reach the invasive organisms, and be utilized by them.

It is clearly not the purpose of this paper to discuss the factors other than the use of sugar in the treatment of these cases; all that is hoped for here is to present the development of the subject of intestinal bacteriology in so far as I have had a hand in it, and to show that these purely laboratory studies can be made use of in the therapeutics of the intestinal canal.

It is obvious that this general principle of fermentation taking precedence over putrefaction can be made use of in many instances, both medical and industrial, in which bacterial activity plays a rôle.

THE TREATMENT OF SUPPURATIVE OTITIS MEDIA (SCARLATINAL) BY BACTERIAL VACCINES (BACTERINS)*

BASED ON ONE HUNDRED CASES OF PATIENTS TREATED IN THE PHILADELPHIA HOSPITAL FOR CONTAGIOUS DISEASES, BUREAU OF HEALTH

PAUL G. WESTON, M.D.
Associate Professor of Pathology and Bacteriology, Temple University, Philadelphia; Pathologist, Philadelphia Hospital for Contagious Diseases

AND

JOHN A. KOLMER, M.D.
Assistant Bacteriologist, Bureau of Health, Philadelphia; Assistant Pathologist to the Philadelphia Hospital for Contagious Diseases

PHILADELPHIA

The treatment of various subacute and chronic infections by means of bacterial vaccines has been successful enough to offer encouragement as a practical therapeutic measure, and we undertook the treatment of suppurative otitis media by this means. Of the sequelæ of scarlet fever, otitis media is one of the most troublesome and dangerous, both to the patient and the public health in general. Of 2,537 patients received in the scarlet-fever hospital from June 1, 1907, to June 1, 1909, 308 patients, or 8.2 per cent., developed suppurative otitis media. The usual treatment is unsatisfactory in many respects; the duration of otitis media is frequently prolonged; the contagium of scarlet fever, whatever it may be, seems almost certainly present in ear discharges; the dismissal of a patient with such aural discharges is thus dangerous to public health; therefore any treatment which will cure these patients more quickly and more satisfactorily than the usual methods will be certainly most welcome. The treatment of these infections by bacterial vaccines is based on good reason, although mostly theoretical. The results have been fairly satisfactory when a good technic has been followed, so that we commenced this work with the realization that of all forms of treatment, this is one of scientific aspect, and that results must be given in an impartial and scientific manner; in other words, the report is a plain statement of facts, whether such be favorable or otherwise.

The theory of the action of bacterial vaccines as promulgated by Wright is well known to every one. He has demonstrated the presence of a substance in the blood which prepares organisms for phagocytosis. These substances, opsonins, are normally present in the blood in varying amounts. They can be increased by the administration of an emulsion of bacteria which have been killed by heat at the minimum degree of temperature (vaccine). If the offending organism itself can be secured and used in the preparation of the vaccine (autogenous), better results will follow. The opsonins are probably formed in part by connective tissue cells, both generally, and locally at the site of injection. This is the reason for selecting the area of administration as near the lesion as possible.

The present study is based on the treatment of one hundred cases, extending over a period of nine months. Otitis media is a condition offering good hope for success by vaccine treatment, because the condition is local; the offending organisms can usually be easily secured; the infection soon becomes subacute and chronic and the results of treatment can be readily observed. The onset of the disease is frequently most insidious; a large number of children do not complain at all, and the first indication of trouble is the presence of discharge. On the other hand, many adults and older children suffer considerable pain. In a series of 406 cases the discharge first appeared on the following days of the illness, reckoning from the day of onset of the scarlet fever:

Day of Illness	No. of Cases	Day of Illness	No. of Cases
1 to 5	27	20 to 35	81
5 to 10	97	35 to 49	35
10 to 20	155	49 to 84	11

Patients suffering with severe throat symptoms are most likely to develop suppurative otitis media by direct infection through the Eustachian tube. On the other hand, cases are apparently produced either by general blood infection or by the toxins of the disease.

The first question is that concerning the best time for commencing vaccine treatment of cases of otitis media. Certain it is that a proportion of patients will recover in a reasonable length of time if left alone or given simple local treatment. It is equally certain that a proportion continue discharging for a long period of time, it may be for the remainder of life, the soft parts and finally the osseous tissue being involved. Experience has demonstrated that it is not wise to commence too early, and it is equally bad practice to wait too long, because long-standing cases are likely to be more refractory to treatment and the mechanism of hearing may be considerably damaged. During the acme and early decline of scarlet fever the patient may be having considerable fever; he may be toxic enough without the addition of vaccine or be suffering with acute nephritis and its accompanying toxemia; finally the general condition may be so poor and the body defences so busy combating the toxic condition that the administration of vaccine will evoke no favorable response, but produce injury by a prolonged negative phase, during which the organisms work increasing havoc. We commenced vaccine treatment in our cases according to the following table, reckoning from the first day of the onset of the otitis media as indicated by the presence of discharge:

Time of Discharge	No. of Cases
Third to seventh day	6
Seventh to fourteenth day	33
Second to third week	21
Third to eighth week	28
Eighth to fourteenth week	10
Four years	1
Ten years	1

According to our experience the best results were secured, considering all things, when cases were reported on the third day of the discharge. This enables one to watch the patient for a day or so; take a culture; consume five or six days in isolating the organisms and preparing the vaccine. If at the end of this time the patient's general condition was fair and he was free of fever, nephritis and toxemia, a dose of vaccine was administered. If his condition was not favorable, the vaccine was put aside in a refrigerator. If at the end of ten days his condition warranted commencing the treatment, we did not use the first vaccine, for frequently a reculture will show a different organism or the presence of an additional offender. A reculture is made from the discharge and another vaccine prepared.

---

* Read before the Annual Meeting of the American Public Health Association, Milwaukee, Sept. 5, 1910; also read before the Philadelphia County Medical Society, Nov. 23, 1910.

* For the sake of brevity references to the literature which appear in the author's reprints have been omitted in The Journal.

The following table is a list of the organisms isolated from cultures of the 100 cases. If the otitis media was bilateral a culture was taken from each ear. If two organisms were found, each was isolated and a separate vaccine prepared. When administering two vaccines to the same patient, the aggregate dose was that equalling the dose of one organism. The bacteriology was comparatively simple and isolation readily accomplished:

Staphylococcus aureus	was found alone in 14 cases
Staphylococcus albus	was found alone in 2 cases
Bacillus pseudodiphtheriæ	was found alone in 35 cases
Bacillus pyocyaneus	was found alone in 20 cases
Streptococcus pyogenes	was found alone in 4 cases
Staphylococcus aureus and *B. Pseudodiphtheriæ*	were found together in 9 cases
Streptococcus pyogenes and *B. Pseudodiphtheriæ*	were found together in 4 cases
Bacillus pyocyaneus and *B. Pseudodiphtheriæ*	were found together in 9 cases
Streptococcus pyogenes and *B. pyocyaneus*	were found together in 3 cases

If no improvement was noted after the third dose of vaccine, or if ten days elapsed before vaccine could be administered to a case after culture had been taken, a reculture was made and a new vaccine prepared. In many cases, an ear cultured three to four days after the onset of discharge will show the *Staphylococcus aureus*; while on reculture at a later date the *Bacillus pseudodiphtheriæ* will be found. Most of the long-standing cases yield *Bacillus pyocyaneus*, and repeated culturing can secure nothing else. The following table gives the list of organisms secured by recultures:

Bacillus pyocyaneus	was found alone in 20 cases
Bacillus pseudodiphtheriæ	was found alone in 6 cases
Staphylococcus aureus	was found alone in 2 cases
Bacillus pseudodiphtheriæ	was found in combination with *Streptococcus pyogenes*; once with *Bacillus pyocyaneus*, and twice with the *Staphylococcus aureus*.

Cases cultured on the third or fourth day of discharge show the *Staphylococcus aureus* in many instances. A vaccine prepared of this organism usually gives good results. A week or ten days later it is often replaced by the *Bacillus pseudodiphtheriæ*, or this organism is found in addition.

It may be well to add here a few words in explanation of the term "pseudodiphtheriæ." We are aware that many opinions exist on what should be thus named. We apply that term here to a solid type of diphtheria-like organism resembling some of the solid types of true diphtheria bacilli, but without virulence or toxicity when tested in a reliable manner by animal inoculation.

We have frequently encountered, isolated, and cultured a short, thick, solid bacillus having rounded ends, with slightly marked median band, characteristic of the *Bacillus hofmanni*. We could never foretell by microscopic examination alone whether solid types of diphtheria-like bacilli were or were not virulent, but relied on an animal test for such information. We believe that a true pseudodiphtheria bacillus exists which belongs to the family of diphtheria bacilli, but have never been able to recognize it with confidence by mere microscopic examination. Twenty-two of the cultures were tested by guinea-pig inoculation and found negative. Two additional cultures, isolated from discharging ears in the diphtheria wards, produced most virulent toxins. Therefore, we believe that the presence of diphtheria-like organisms in the ear can be determined by microscopic examination, but only an animal test can determine whether or not the organisms possess virulence and are a menace to public health. The presence of this organism in 57 per cent. of the cases shows its important position in the etiology of otitis media and its relation to diphtheria of the ear.

The *Bacillus pyocyaneus* was found in 20 per cent. of cases discharging for four weeks or longer. This organism is believed by many to be a practically harmless saprophyte, feeding on tissues killed by some other organism. In 10 per cent. of our cases this was found alone or in combination with some other organism as early as the third to fourteenth day of discharge. The results of its vaccine were satisfactory in these early cases, and while the administration of a vaccine prepared from this organism may have been merely coincident to a rapid cure, yet we cannot agree with those who claim its vaccine to be practically without effect, for we believe that it is at least worthy of trial. On the other hand, of the fifteen patients dismissed from the hospital with persistent discharging ears, thirteen gave this organism in pure culture and its vaccine did not produce favorable results.

All of the various groups of streptococci are here listed under one name. A vaccine prepared from this organism gave quick and favorable results each time. It was found alone or in combination in 11 per cent. of cases.

We prepared and used autogenous vaccines for every case except one. This case was one of ten years' standing, following measles. The patient was admitted with scarlet fever and recovered in a satisfactory manner. He was detained, however, on account of the discharging ears, for although the otitis did not develop during the course of scarlet fever, yet his ear discharge was most likely infected, and therefore it was considered dangerous to dismiss the patient. Repeated cultures yielded the *Bacillus pyocyaneus*. A vaccine produced some improvement. Then a stock culture of *Staphylococcus aureus* and *Bacillus pseudodiphtheriæ* was tried. Granulation was rapid and all discharge ceased after the fourth dose. His ears were dry for ten days before dismissal from the hospital.

The question of dosage has always been one of paramount importance in vaccine therapy. Wright's technic for determining the opsonic index was received as being an exact guide to amount and frequency of dosage. There is considerable evidence to show that its practical value has been overestimated, and while in skilful and exact hands its results are of aid, yet the procedure consumes so much time and its results are apt to be so misleading, unless performed in an exact, patient manner, that it can be well dispensed with in ordinary practical work. We learned to rely more and more on the clinical aspect of our patients. It is very important to avoid producing a prolonged negative phase, or giving a dose of vaccine during this period. Careful opsonic work has demonstrated what usually occurs after the administration of a vaccine and the importance of avoiding this phase of the reaction. We have frequently seen the harmful effects of too large a dose at too close an interval between doses. The tendency is to give smaller doses with longer intervals between each. As a rule the sicker and weaker the patient, the smaller the dose. In this work no fixed rules of dosage were used. Each case is a law unto itself. Dosage must be controlled in each patient according to temperature reaction and the local and general condition of the patient. The initial dose for the average patient 10 years of age was about as follows:

Staphylococcus aureus and albus,	15 to 40 millions
Bacillus pseudodiphtheriæ,	30 to 50 millions
Streptococcus pyogenes,	5 to 10 millions
Bacillus pyocyaneus,	50 to 80 millions

It is well to give a small dose at first and note the extent of the reaction. This reaction will be a good guide for determining the size of the succeeding dose. Doses were repeated every five to eight days. In our earlier cases they were given at shorter intervals, but results did not warrant the continuance of the practice. Succeeding doses were increased by five to ten millions if necessary. Following the administration, the majority of patients develop a temperature varying from 100 to 102 F. in about eight hours, gradually reaching normal in twenty-four to thirty-six hours. We have seen the temperature fall a degree or so to subnormal after an injection, reaching normal at the end of twenty-four hours. A second dose should not produce so much fever, and when doses are properly selected, the temperature reactions are quite conspicuous, each being lower than the preceding, as the patient's system is charged with an increasing quantity of opsonins, until finally no fever follows the administration. The local reaction is usually quite typical. If one has succeeded in securing the organisms producing the infection its vaccine will produce an increased amount of discharge for twenty-four to thirty-six hours. This is of good prognostic value. The discharge may gradually diminish in amount or cease suddenly and entirely. The general improvement in health in many of the patients was indeed striking. It is difficult to decide what proportion of good may be ascribed to the vaccine, but certain it is that improvement in nutrition so frequently followed the administration of the vaccine that one was forced to notice the relation. It may be that the injection of the vaccine served as a stimulus to the increased production of receptors which were used in anchoring additional nutritive material. In addition to the temperature and local reaction the patient, if old enough to express himself, will sometimes complain of lassitude, sleepiness, slight headache, etc. We have been fortunate enough to escape abscess formation. Streptococcus vaccine in every case produced a local reaction of redness and pain at the site of infection, which passed away in twenty-four hours with rest and evaporating lotions.

As in all hypodermatic medication, it is necessary to use an accurate syringe. This is especially true in vaccine work because wasting even a few drops alters the size of the dose to an extent difficult to compute. We gave the injection in the loose areolar tissue over one of the scapulæ. Since children frequently sleep on the abdomen we made it a practice to administer the vac-ine at night when the part could be cleansed and when he injection was given frequently without awakening he child. The temperature, pulse and respiration of he patients were taken every four hours for the first wenty-four hours, and longer, if necessary, until the ormal was reached. Notes were made every other day n the progress of the case.

During the administration of vaccines every other orm of treatment was suspended. Syringing the ears vas especially interdicted, for unless it is performed in a kilful manner, and with a proper syringe, more harm han good may result by reinfection of healthy parts. Four of our cases were persistently refractory for over three weeks, when it was learned that the nurse in charge was syringing out the ears with great zeal through an oversight, not having been instructed to stop all treatment. These cases rapidly progressed in a favorable manner to ultimate cure when this local treatment was stopped. No treatment is given, except wiping away the secretions when discharged over the neck and cheek. The ordinary cotton plug in the canal frequently does no more than dam back the secretions. Once or twice a day the external auditory canal is gently cleansed with cotton and applicator to avoid inspissation and consequent plugging.

The following table shows the number of doses given to secure a favorable result, or convince one that vaccines were giving no aid:

16 patients	received	1 dose	(13 cured; 3 died).
11 patients	received	2 doses	(10 cured; 1 improved).
15 patients	received	3 doses	(14 cured; 1 improved).
10 patients	received	4 doses	(10 cured).
10 patients	received	5 doses	(9 cured; 1 improved).
9 patients	received	6 doses	(8 cured; 1 not improved).
4 patients	received	7 doses	(4 cured).
4 patients	received	8 doses	(2 cured; 1 improved; 1 not improved).
3 patients	received	9 doses	(3 cured).
3 patients	received	10 doses	(2 cured; 1 improved).
4 patients	received	11 doses	(1 cured; 3 improved).
3 patients	received	12 doses	(2 cured; 1 improved).
3 patients	received	14 doses	(1 cured; 1 improved; 1 not improved).
1 patient	received	15 doses	(1 not improved).
1 patient	received	16 doses	(1 cured).
1 patient	received	17 doses	(1 cured).
2 patients	received	18 doses	(2 cured).

If the otitis has been present for a considerable length of time the bony parts are affected, and consequently the time required for cure will likely be longer. Even after the infection has subsided a discharge of necrotic material or secretions of granulation may be present for some time. On the other hand, there are cases in which suppuration will progress most actively despite all one may do. These cases have been repeatedly cultured, and as many as six vaccines prepared for each case but with no beneficial result. All such patients were in a poor physical condition.

It is a difficult matter to decide when an ear is cured. Often the discharge may cease entirely for a few days or a week, and then commence again. It is customary in the Philadelphia Hospital for Contagious Diseases to retain all such patients until the ears have been constantly "dry" for a week or ten days. If the time required for such a result reaches four months the patient is discharged, for while the ears may be suppurating, they are not likely to be contagious. Most of the cases under vaccine treatment progress gradually in a favorable manner, although many stop discharging quite abruptly with one or two doses of vaccine. It is necessary to guard against supposing an ear free of discharge when cerumen is plugging a perforation of the tympanum. The longer the time one can observe these patients after cessation of discharge the better will one be enabled to judge of what the ultimate outcome will be. Practically all patients with scarlet fever are detained in the hospital for at least five to six weeks. At the expiration of this time parents are very anxious to have their children returned, and if they are detained longer, as in cases of otitis media, this anxiety is often under high pressure.

We have always endeavored to watch a case for at least ten days after all discharge has ceased. Most of our cases were from the poorer crowded sections of the city where it is a very difficult matter to keep trace of them after dismissal from the hospital. The final test of value of any form of treatment can be judged only by results after a long lapse of time. The following table gives the number of days in which cases were "dry" preceding discharge from the hospital:

4 to 10 days	37 cases
10 to 18 days	27 cases
18 to 28 days	11 cases.
28 to 42 days	6 cases
3 months	1 case

Each case was thoroughly examined by Dr. Woody, chief resident physician of the hospital, three times before dismissal.

As already stated, the real value of the vaccine treatment in these cases of otitis media can be determined only at a much later data. However no "return" cases have been traced either directly or remotely to any of these patients. At the present we can estimate the value of the vaccine treatment by considering the time required to accomplish a cure under the usual form of treatment and that required under vaccines; also by the number of patients dismissed at the expiration of three to four months with ears still discharging. To determine this the records of the hospital have been studied and the results tabulated (Woody):

The table is very important because it compares the percentage of patients who were cured under the usual treatment with those cured under vaccine treatment during an equal number of days:

Number of cases admitted to Scarlet-Fever Hospital from June 1, 1907, to June 1, 1909, 2,537.

Number of cases of suppurative otitis media developing during this period, 308, or 8.2 per cent.

	Usual Treatment.	Vaccine Treatment.
1 to 10 days	3.24 % cured	22 % cured
10 to 20 days	7.47 % cured	22 % cured
20 to 30 days	11.69 % cured	21 % cured
30 to 40 days	17.86 % cured	8 % cured
40 to 60 days	19.15 % cured	4 % cured
60 to 90 days	9.41 % cured	4 % cured
90 to 120 days	2.28 % cured	1 % cured
Dismissed with ears still discharging	13.96 %	15 %
Died ears still discharging	14.94 %	3 %

This table demonstrates that under vaccine treatment 21.99 per cent. of cases are cured in from one to thirty days as compared to 7.46 per cent. under usual treatment in the same period of time.

Of the fifteen patients receiving vaccine treatment and dismissed with ears still discharging, one was "running" six weeks, and five from twelve to fourteen weeks before vaccine treatment began:

4 received vaccine treatment on fifth to twelfth day of discharge.
5 received vaccine treatment on fourteenth to twenty-eighth day of discharge.
1 received vaccine treatment during sixth week of discharge.
5 received vaccine treatment during twelfth to fourteenth week of discharge.

It is reasonable to suppose that if vaccine treatment had been given to the six patients before the expiration of six weeks and longer, more favorable results would have been obtained.

No deductions can be drawn from the number of patients succumbing with ears discharging. Most of these deaths occurred during the year 1907-1908 when scarlet fever was unusually severe; during 1908-1909, the disease was quite mild, while during 1909-1910, scarlet fever was of moderate severity. In our series of 100 cases the three deaths were caused by the following conditions: two by acute nephritis and one by general toxemia of scarlet fever.

During this work, the following were considered as contra-indications to the administration of vaccines:

1. Cases of continued fever. This condition is frequently a part of the scarlatinal infection. The typhoid type of scarlet fever comes under this category. Such cases are usually of poor vital resistance and vaccines are likely to do more harm than good. However, in selected cases, by means of small cautious doses, the local condition may be held in abeyance or even cured.

2. Acute nephritis. This condition means decreased elimination and retention of toxins. To administer vaccine means adding fuel to a fire. Such cases very frequently show increased activity of the local infection, indicating a general decrease in local and general resistance. It is a safe practice to wait for ten days or two weeks after the total disappearance of albumin from the urine before administering vaccine.

3. The occurrence of other infections means cessation of vaccine treatment. Thus, a patient may develop measles, chicken-pox, diphtheria, etc. Our work was once practically stopped on account of vaccination during a small-pox epidemic, during which time it was found unwise to whip up a well-worked horse.

TECHNIC

The technic employed was essentially that used by Wright and his co-workers. We never administer a mixed vaccine but isolate each organism and make up standardized vaccines from each. As short a time as possible was employed in securing isolation for fear that frequent subculturing would lower the virulence of the organism. It is also necessary to kill the culture at the minimum degree of temperature at the minimum length of time to secure the most potent vaccines. Briefly, it is as follows:

The ear is cleansed of the excess of secretion by means of probe and cotton and then a culture is made in sterile bouillon by means of a sterile swab. This culture is then plated out by inoculating the water of condensation in successive large tubes of plain or gelatin-agar. This water is run once over the surface of the media. In twenty-four hours the colonies are well developed and usually well isolated. They are examined microscopically and subcultures made on large tubes or bottles of slanted agar. If the streptococcus was being cultured, glucose-gelatin-agar was used. At the end of twenty-four hours, the culture is examined microscopically for purity and morphologic characteristics of the organisms; subcultures are made on various media, and in case a diphtheria-like bacillus is present, a toxin is prepared by growing for forty-eight hours in alkaline (0.5 per cent phenolphthalein) bouillon to which is added 1 per cent. glucose. This is administered unfiltered, subcutaneously into the abdominal wall of a 250-gm. guinea-pig, the dose being 0.5 per cent. of the body-weight expressed in cubic centimeters. The cultures are washed off the surface of the medium with sterile normal salt solution, diluted with the same solution and counted by comparing the number of bacteria with human blood as a standard. For staining these slides it is very essential that the stain employed produce no precipitate. We used, and can warmly endorse, the method consisting of fixation for five minutes in a saturated solution of bichlorid of mercury, followed by washing and immersion in a solution of carbol-thionin for a few minutes. After counting, the emulsion is sealed in a drawn out test tube and heated in a water bath, fully immersed, for one hour at 58 to 60 C., never over 60. The tubes are then opened and cultures made on slanted agar.

The tubes are then sealed again and put aside in the refrigerator for twenty-four hours to await the outcome of the cultures. Streptococcic vaccine is always allowed forty-eight to seventy-two hours in determining whether it be sterile, because this organism grows so slowly. If sterile, the tubes are opened and the proper dose prepared by diluting with sterile salt solution, with compound solution of cresol added as a preservative. The dose is put up in amounts of one cubic centimeter in sterile ampoules or in a sterile stock bottle. When not in use they are stored away in a cool place.

CONCLUSIONS

We have tentatively drawn the following conclusions:

1. The best time, all things considered, for commencing vaccine treatment in cases of otitis media, is from the eighth to the sixteenth day of the discharge.

2. Continued high fever, nephritis, toxemia and various intercurrent affections *are contra-indications to the administration of vaccines.*

3. Under vaccine treatment. three times as many *patients are cured within thirty days and permitted to* go home as under the usual treatment. This means that the average residence of a patient in the hospital has *been considerably decreased.*

4. In general, cases of otitis media offer a fruitful and encouraging field for the employment of vaccine therapy.

MULTIPLE MYELOMA WITH ALBUMOSURIA

REPORT OF A CASE

JOSEPH M. KING. M.D.

LOS ANGELES

The first recorded case of albumose in considerable amount in the urine with accompanying destructive lesion of bone was reported by Henry Bence-Jones[1] of London. before the Royal Society of London, in 1874.

The urine was from a male patient, a grocer, aged 45, who dated his illness from a violent strain in vaulting from a cavern, accompanied at the time by violent pain in the chest, and who. after sixteen months' illness, died. is case occurred in the practice of a Dr. MacIntire. he autopsy Bence-Jones remarked, "I saw that the structure of the ribs was cut with the greatest ease the bodies of the vertebræ were capable of being sliced off with a knife." Microscopically, their interior presented "granular matter, oil globules, nucleated cells. constituting the bulk of the mass—a few caudate cells and blood-disks extravasated largely among the other cells, and giving the red color to the gelatiniform mass."

The post-mortem diagnosis was "osteomalacia fragilis rubra."

But few cases were recognized and reported up to 1890. Since that time an increasing number of cases has been recognized, but the condition is still far from common.

A large number of names have been given to the condition, the one of multiple myeloma, now universally used, *having been given to it by* J. von Rustizky, in 1873,[2] who, however, regarded the condition as simply over-growth of the cell-elements of the bone-marrow.

It attacks the old rather than the young, occurring in males more often than females, and usually runs its course within two years. The condition is one of primary tumor formation taking place in the red marrow of the bones. It is. therefore, most apt to occur in the sternum. ribs. vertebræ, and skull, although the long bones are by no means exempt. It usually appears simultaneously in several foci, often in bones widely separated. The growth resembles a small round-celled or lymphosarcoma. but differs from it in very seldom forming metastases. only one or two cases being reported,[3] and in not containing spindle or giant-cells. It forms soft, reddish masses, with yellowish or grayish streaks, is homogeneous in appearance, not sharply defined from the surrounding tissue, and replaces the normal red bone-marrow. The cortex of the bone is also usually very much thinned and bulging or broken through, and the tumor forms nodular masses on the surface or may even invade the neighboring soft parts by continuity of growth. Spontaneous fractures not *infrequently* occur. If the vertebræ are involved, curvature of the spine or kyphosis frequently occurs, with its accompanying pressure symptoms. In pure cases the *affection* is confined to the bony system, no enlargement of the spleen or liver, or involvement of the lymph glands taking place. In a considerable number of the *reported* cases enlargement of the spleen or liver or both has been noted.

The blood is markedly affected, resembling grave forms of secondary anemia, or a pernicious anemia. Leukocytosis is not common.

The best descriptions of the histologic structure are those of Henry A. Christian,[4] W. G. MacCallum,[5] and James Homer Wright.[6]

The tumor masses are very cellular in type, with a scanty, loose, wide-meshed connective tissue stroma, usually composed of very fine fibrils, in which loosely lie round or oval cells, sometimes polygonal in shape and interspersed with numerous large and imperfectly defined blood-vessels. Often many red blood-cells are seen scattered among the cells. These tumor cells are from 8 to 12 microns in length by 4 to 10 microns in width. The cell outline may be sharp, but there is not often a definite cell-membrane. and the cells are made up of a very finely granular slightly basophilic protoplasm, in which lies a rather large round or oval vesicular nucleus, often eccentrically placed, having a definite *nuclear* membrane. Two or three nuclei, each of the vesicular type, are not uncommon. The nucleus contains a chromatin network with chromatin masses usually *peripherally* placed. It also contains a nucleolus. No specific granulations are found. Much discussion has arisen as to whether these cells more nearly resemble and *spring from the premyelocytes, or from the bone-marrow* plasma-cells. The best evidence at hand seems to indicate that they are of plasma-cell origin.

In 1901 Hamburger[7] developed the clinical manifestations of the condition.

The chief clinical features are attacks of pain referred to some portion of the osseous system. often with the formation later of visible or palpable tumors, cachexia, and the presence of Bence-Jones albumose in the urine. Frequently the patient's first complaint is of rheumatoid symptoms; and stiffness of the small joints, as of the hands, may develop. Dull pain over the hips, patella, or vertebral column is also noted among the early symptoms, or perhaps sharp pain over a rib or the chest is the initial symptom, or the first complaint is of a seeming lumbago or sciatica. These painful periods often alternate with periods of comparative comfort. but any unusual muscular exertion or contusion of affected parts is liable to call forth a return of the pain. While pain is a predominant feature in many cases, in others it is entirely absent. As the disease progresses, visible changes in the bones are apt to appear. Bending of the vertebral column is common. The sternum also sometimes bends, and tumors on the ribs, sternum, cranium or about the joints are often present. Fractures, spontaneous, or caused by very slight injury, sometimes occur. *In a considerable proportion of cases,* no bone changes are demonstrable clinically. The *x*-ray may be a very great aid. showing rarefaction and thinning of the cortex of the bones. particularly the ribs, where a wavy outline may be made out.

With the progression of the disease the patient loses flesh and strength; the general health suffers; the appetite is poor; nausea sometimes occurs; and an anemia of the secondary type develops, gradually passing to a most severe type. Leukocytosis is not common, although it has been reported in some instances. In typical cases the spleen, liver, and lymph-glands are not enlarged.

The most distinctive sign, however, is to be found in the urine, in the presence of the Bence-Jones body, which is virtually diagnostic. It is not invariably present, but the exceptions are rare. As a rule it occurs early and persists until the end, although there may be marked remissions, and the percentage usually varies considerably from time to time. The amount of urine is usually increased, averaging about 2,000 c.c. daily, often slightly cloudy, very pale in color, either neutral or very slightly acid, and with a specific gravity averaging from 1.004 to 1.012. On applying Heller's test a white ring forms, and as the contained albumose is also thrown down by the Esbach reagent, it is often mistaken for ordinary albumin. When heated, however, it is found to become cloudy at from 50 to 60 C. This turbidity can be made to disappear by the addition of acetic acid; or by further heating to the boiling point it disappears in great part, to precipitate again on cooling. The urine usually gives a strong biuret reaction. Casts are seldom seen. Owing to the increased amount of urine passed, thirst is a rather common symptom. Peptonuria of slight degree is an accompaniment of many disorders, but the presence of albumose in so large amount as to alter the usual reactions of the urine is practically found only in distinctive lesions of bone, and then only in that particular lesion termed multiple myeloma. The percentage present in the urine varies greatly, from 0.25 of 1 per cent to 6.90 per cent., which high amount was reached in Bence-Jones' famous case. Its origin is unknown, although Weber[8] and others regard the bone-marrow as the seat of its production. It is often accompanied in the urine by traces of albumin. No other changes are commonly present.

The heart sounds may be accompanied by hemic murmurs, and while the condition does not usually give rise to pathologic changes in its musculature, attacks of angina have been reported in several cases.

Chilly sensations, fever and sweats and slight jaundice occur in some cases, but they seem to be the accompaniments of the rapid destruction of blood and blood-forming tissue, and not to be in any sense distinctive of this condition. So also, and from the same causes, serous effusions may occur.

If no demonstrable lesion is found in the bones, the physical examination is usually negative.

The diagnosis may be difficult, particularly if the Bence-Jones body, which is almost diagnostic, is absent.

Weber[8] gives a careful differentiation. Osteomalacia differs by more often attacking women during the child-bearing period, affecting chiefly the bones of the pelvis and lower extremities, giving rise to great deformity and bending of the bones, but not so frequently to spontaneous fractures.

Caries of the spinal column gives a more distinctly angular kyphosis, the ribs are not likely to be simultaneously affected, and the anemia is seldom so marked.

The presence of obvious bone disease, a leukocytosis of any degree, or of albumose in the urine, serves to distinguish the condition from pernicious anemia. Furthermore, the superficial fat is not well preserved, nor is there a lemon-yellow cast to the skin. From nephritis it is distinguished by a sufficiently careful examination of the urine.

The prognosis is bad, the patients having died in all recorded cases, generally within two years, although one patient is reported as having lived seven years from the first symptoms.

Treatment seems unavailing. Arsenic and the *x*-rays have been used. Only symptomatic treatment seems to be of any value.

The following case, while not a pure case of myeloma, in that it had a considerable leukocytosis together with hyperplasia of the spleen and liver, is yet to be classed among those of this tumor.

History.—E. J. A., male, aged 60, married, born in Canada of English parentage, a liveryman by occupation, first consulted me July 12, 1910, complaining of great weakness with inability to stand on his feet, with numbness in his legs, shortness of breath on exertion, fulness of the stomach after eating, and somewhat frequent urination. He had a wife, son and daughter living and in good health. His father died at 69, after a nine weeks' sickness of "paralysis of the lower limbs." His mother died at 88. One brother died in babyhood, a sister died of typhoid at 28, and two sisters, aged, respectively, 63 and 58, were living and in good health.

The habits of the patient were excellent. He had never had any venereal diseases, used no tobacco and only very occasionally took a glass or two of beer. He had suffered from the diseases of childhood, and stated that he had had typhoid fever three times, the last twenty years previously. In 1898 he was laid up three months with lumbago and "nervous prostration," but had fully recovered, and had been in perfect health for years. He gave no history of malaria or injury in the splenic region or elsewhere. He had suffered from an indefinite stomach trouble for some time. In September, 1909, he contracted what he thought was a severe bronchitis, with much cough and expectoration, which lasted for about three months, and reduced the patient somewhat in weight and considerably in strength. He at length recovered, however, and about Christmas felt fairly well.

In January, 1910, a sharp pain came on at the costal margin on both sides, made worse by exertion, lifting, etc., but especially by raising the arms. This attack lasted about six weeks. From this the patient did not fully recover; he never regained his normal strength. He had no fever at any time. This weakness increased, and about May 1 a dull pain came in the back, with numbness in the legs and inability to stand. Shortness of breath on exertion appeared about the same time and gradually increased. He did not now have any sharp pain, his appetite became poorer and he had distress in the epigastrium after eating. He gradually lost weight and strength, but no other symptoms developed prior to my examination on July 12.

Examination.—This revealed a man about 5 feet 10 inches tall, weighing 140 pounds, of large frame and much emaciated. He looked anemic, and the mucous membranes were very pale. The superficial fat was not well retained; there was no yellowness of the sclera. No cervical pulsation was noted, but the femorals were throbbing. No enlarged glands were noted. The pulse was not rapid, was very regular, but collapsing in quality. No abnormality was noted in the lungs. The area of cardiac dulness was not increased; the apex-beat could not be seen or felt, and the sounds were very weak. No murmurs were heard. The patient was tender in the upper part of the abdomen, and on examination it was found that the liver was palpable for 1½ to 2 inches below the costal margin, and that the spleen extended to the level of the umbilicus and the left mammillary line. When the patient arose in bed he held the spine rigid, as he also did in bending. No error in alignment of the vertebræ or tenderness on percussion was present. The pupils reacted normally to light and accommodation. The knee-jerks were lost, and most of the other deep reflexes of the body were feeble. Romberg's symptom was not present. The

---

8. Webster, F. P.: Am. Jour. Med. Sc., 1903, cxxvi, 644.

patient reeled and complained of pain in the back when walking. He was very weak. Temperature was normal. The patient had at this time no cough or expectoration. Tuberculin tests were negative.

The blood showed hemoglobin, 20 per cent. (Dare); reds, 1,284,000; whites, 19,000. Stained specimens showed some poikilocytosis. No megalocytes were present, although there was some anisocytosis. Most of the cells looked small. Many normoblasts and some megaloblasts were seen, the latter showing all degrees of polychromatophilia. Some were absolutely basophilic.

A differential count showed polynuclears 23.5 per cent., small lymphocytes 50 per cent., large lymphocytes and transitionals and large mononuclears 21.5 per cent., eosinophils 3 per cent., basophils 2 per cent. For each 100 white cells there were sixteen nucleated reds, thus giving 3,040 nucleated red cells per cubic millimeter. Of these about 75 per cent. were normoblasts and 25 per cent. megaloblasts.

Several careful examinations of the patient's blood were made at intervals, but no marked change from this description occurred.

It was noted that the patient was passing large amounts of urine, a symptom of which he had complained, and on measuring, it was found to amount to about 2,000 c.c. daily. This was usually slightly cloudy, very pale, for the first week or ten days of observation slightly greenish in color, later becoming pale yellow. Its specific gravity was always about 1,008. It was very slightly acid in reaction. No serum albumin or sugar was present. When heated to about 56 C., however, it became opaque with the formation of a flocculent precipitate. This could be dissolved by the addition of acetic acid; if heated to the boiling point, it almost cleared, to again become very cloudy on cooling. When measured with an Esbach albuminometer this albumose was found to amount to 2 gm. to the liter. This Bence-Jones body varied considerably in amount, but was never absent from the urine during the remaining life of the patient, usually from 1 to 2 gm. to the liter. The urine was also found to contain enormous amounts of indican, and as the taking of methylene blue or other drugs, which might cause the urine to become green, could be absolutely eliminated, the color was supposed to be caused by the excessive excretion of this substance. It also blackened the precipitate of albumose on boiling. After passing the urine through the centrifuge a few hyaline casts could usually be found. After the discovery of the Bence-Jones body a very careful examination of the patient's bones was made, but nothing whatever could be detected, except a slight tenderness on percussion over the lower part of the sternum.

This condition continued without much change, except ever-increasing weakness, until the patient's death on July 28, due to his extreme anemia.

Necropsy.—This was performed nine hours after death. It revealed an emaciated man, about 60 years of age, 5 feet 10 inches tall, weighing about 125 pounds. There was no livor of the dependent parts. The superficial fat was not well retained. The cutaneous surfaces were very pale, but not jaundiced. The muscles of the abdomen and thorax were apparently normal. The cut surfaces of the costal cartilages appeared much whiter than usual. The sternum proved very fragile, and was broken twice in the attempt to remove it. There were slight recent adhesions in the right pleural cavity, but no fluid. The left pleural cavity was normal, as were also the lungs, with the exception of some hypostatic congestion at the bases. When the lungs were raised out of the chest the ribs were noted to have a wavy surface, caused by masses varying the size of from a pea to that of an almond. These masses were present on practically every rib, and looked as though the cortex had been bulged out in spots. The cortex was not broken anywhere. The ribs were very fragile and easily broken, and the sternum and ribs were easily cut through, showing a wavy outline, with the cortex very much thinned, and the medullary portion made up of a soft, moist, dark red tissue. This was continuous throughout the sternum, but alternating in the ribs with areas of grayish marrow, into which the reddish tissue insensibly merged. Examination of the right femur showed it to be normal. The bodies of the vertebræ were not sawn through, nor was the skull-cap removed. The pericardium was normal. The heart was normal in size, with normal endocardium and valves. The myocardium, however, showed fatty degeneration.

The liver was much enlarged, reaching almost to the level of the umbilicus. The gall-bladder was distended and fixed by firm adhesions to the liver. It could be emptied into the bowel by gentle pressure. No stones were present.

The mesentery of the transverse colon was firmly adherent to the under surface of the liver. On section, the liver was softer and paler than normal.

The spleen, which was very soft, measured 8 by 5½ by 2¼ inches, and weighed about 3¼ pounds, and had the appearance of a leukemic spleen.

The small intestines seemed very much contracted. No abnormalities were noted in their walls, and no ulcerations were present. With the exception of fatty degenerative changes, all the other abdominal organs were normal. None of the lymph-glands of the body were enlarged.

A section of rib, examined by Dr. Stanley P. Black, revealed the histologic structure to be practically that described by Christian.

AN EMERGENCY CULTURE MEDIUM FOR USE IN PRACTICE

FRANK M. WOOD, M.D.
CHICAGO

In general practice there are repeated demands for a culture medium which is, at the same time, cheap and easily prepared from the materials at hand. This is especially true when the physician desires to grow bacteria for the preparation of bacterial vaccines. The usual culture media are expensive and difficult to obtain, the apparatus necessary for their preparation is extensive, and the technic of preparation is long and tedious. Therefore, the demand for a special emergency medium is great.

Bacteria grow on ordinary artificial media under unnatural conditions and their character is often quickly changed by the new ingredients of the media. Some species cannot be grown without special care; this is true of the pneumococcus, the streptococcus and the gonococcus. These cocci do not grow readily; it is difficult to keep them alive, and their virulence is often lost after two days' culture, unless they are surrounded by the nourishment afforded by human secretions. The problem is to supply them with conditions as nearly as possible like those which they find in the human subject.

I experimented for several years with agar-agar, Loeffler's blood-serum, bouillon, milk and potato, and noted the effects of various salts and chemicals in solution on the growth of bacteria. I also followed the experimental work done in the physiologic laboratories: the use of normal salt solution to preserve skin grafts; the work of Dr. Loeb at the University of Chicago with amebas in salt solution; the power of salt solution to preserve the life of the cells in the blood-vessels and heart of the frog, and finally the suspension of the leukocytes in normal saline solution in performing the various experiments in determining the opsonic index. These studies led me to think that normal salt solution might keep bacteria alive. I found that if sufficient material from the site of the infection were added to 2 drams of normal salt solution, in a sterile bottle or test-tube, and incubated at body temperature, many of the ordinary bacteria could be grown and kept alive for weeks and even months, and that in some strains the virulence seemed to be maintained longer than when grown on the ordinary media.

This method can be used to transfer culture material from the office of the general practitioner to his laboratory or to that of the laboratory specialist, and will be found of distinct advantage in transporting infectious material over long distances. All that is needed is a sterile bottle containing sterile, normal salt solution, in which is suspended some of the discharge from the point of infection, the discharge having been obtained under aseptic precautions. It is important to obtain a liberal amount of the material from the site of infection, in order to furnish the infecting bacteria with sufficient provender.

There are some exceptions among bacteria; some will not grow in salt solution, and doubtless others will be found. Pneumococci can be kept alive in it only a very short time, and are completely dissolved (autolyzed) in four days, as noted by Rosenow. Streptococci do not grow well unless serum from the site of the infection be added, but this can easily be done. Staphylococci, *Bacillus typhosus*, *Bacillus coli communis* and *Bacillus pyocyaneus* can be readily grown. The gonococcus can be grown in salt solution by the addition of a liberal supply of human blood to a free supply of secretion from the infecting area. Diphtheria bacilli grow with difficulty, but can be grown in salt solution by the addition of a few drops of human blood-serum or sterile beef bouillon.

It will be noted that all these materials may be obtained at home and with but little trouble and expense. The tubes of cultures thus obtained may be incubated on the person of the doctor or of the patient, care being taken to see that they are well stoppered by stoppers rendered sterile by boiling or steam sterilization.

I offer this preliminary report to those who are interested in bacteriologic work and especially to workers in vaccine therapy, as a ready assistance in such work, with the desire that it may save both time and expense.

34 Washington Street.

SYSTEMIC BLASTOMYCOSIS

REPORT OF A CASE

ROBERT G. WASHBURN, B.S., M.D.
Associate Professor of Dermatology, Marquette University;
Dermatologist to Milwaukee County Hospital
MILWAUKEE, WIS.

During the last decade, blastomycosis cutis has become a well-recognized, distinct, clinical and pathologic entity among dermatologists. Although it is not a common disease, it appears to occur more frequently in this vicinity than it does elsewhere. More cases have been reported from Chicago than from any other one locality, and it is largely to the thorough work of our Chicago confrères that we are indebted for our present knowledge of the disease. Prior to the work of Gilchrist and Stokes in 1896, the disease was mistaken for various other conditions that resemble it in certain respects. The three diseases which have given rise to most difficulty in diagnosis are tuberculosis, syphilis and carcinoma. Blastomycosis resembles very closely the verrucous form of tuberculosis and often a definite diagnosis can only be arrived at after microscopic examination of the tissues or the pus. The lesions of blastomycosis resemble somewhat those of the rarer vegetating forms of syphilis, and if the diagnosis is not established by microscopic examination, the clearing of the lesions under potassium iodid may still further confuse the physician. The resemblance of the lesions to carcinoma is only very superficial and should lead to no difficulty if the history of the case is carefully gone into.

The organism which gives rise to this disease is a fungus much resembling yeast. It is very readily demonstrated in the pus from the lesions by treating the material with liquor potassæ and examining under the microscope with a fairly high power. The organisms resist the action of the alkali and are thus easily distinguished from epithelial cells and pus cells. They are round, oval or slightly irregular in outline and have a well-defined double-contoured homogeneous capsule. The protoplasm is finely or coarsely granular and is separated from the capsule by a clear space of varying width. Budding forms are seen in all stages. No mycelium has as yet been demonstrated in the pus from skin lesions or deeper abscesses, but it is seen in cultures. The organisms grow very readily on artificial media.

The typical skin lesion is so characteristic that to one familiar with the disease, the diagnosis, as a rule, presents very little difficulty. The lesions are elevated from the surface; each has a well-defined border and is covered with irregular papillary elevations, separated by clefts or fissures, giving the whole a verrucous appearance. Portions of the surface are covered by crusts. The border is the most characteristic feature. It slopes abruptly to the normal skin and on close inspection it is seen to be set with a large number of minute abscesses. The pus from these abscesses contains the blastomycetes in large numbers.

The first case of blastomycosis to be recognized was one of systemic infection with the organism reported by Busse and Buschke in 1894. Credit belongs to Gilchrist and Stokes, however, for first describing the typical cutaneous lesions and properly classifying the parasite. Since these reports, a hundred cases or more have been recorded and no doubt many hundreds of cases have been recognized and treated which have not found their way into medical literature.

Recently a number of cases of systemic infection with the organism of blastomycosis have been reported. There are now on record twenty-nine in all; reports of twenty-seven of these were collected and published in a very exhaustive article two years ago by Montgomery and Ormsby. Since that time, one case, the first from the South, has been reported from Memphis, Tennessee, by Fontaine, Haase and Mitchell; and another case has been recorded by Hutchins. To this list I wish to add still another which has recently come under my observation at the Milwaukee County Hospital and which I was able to follow and study with the assistance of Dr. L. M. Warfield.

REPORT OF CASE

The patient was a German laborer, aged 70, who had resided in this country thirty-seven years and had been an inmate of the Milwaukee County Almshouse for four and one-half years. He was first admitted to the County Hospital March 1, 1909, on account of a sore on his right elbow. There was nothing of importance in his past history; he had had typhoid fever, but denied any knowledge of venereal infection.

The present illness dated from three weeks before his admission to the hospital. After a slight trauma, a lesion developed on his elbow. On admission, this lesion was about the size of a silver dollar and presented a purulent granulating surface, with a well-defined margin and somewhat raised above the surrounding skin. This lesion was on the right arm, just over the internal condyle of the humerus. The tissues surrounding this ulcer were edematous. The patient also presented at this time (March 19, 1909) over the vertex of the skull a soft, well-defined mass about the size of a hickory-nut. This was incised and pus evacuated. This pus was not examined. The wound continued open till the time of the patient's death, and necrosis of the outer table of the skull extended until an area 2 inches in diameter was involved. These two lesions, from the subsequent history of the case, were probably blastomycotic, although no definite proof that such was the case could be obtained. The lesion on the elbow slowly healed under local treatment alone. A section, taken from its margin, showed only granulation tissue. The patient was sent back to the almshouse in August, 1909.

Three months later, he was again admitted to the hospital. At this time there were present three lesions, which, from their clinical appearance and the microscopic findings, were undoubtedly blastomycosis. The most typical of these was situated above and to the right of the upper lip and was about the size of a fifty-cent piece. It was raised above the surrounding skin and partly covered by crusts. Along the margins were many miliary abscesses. There was a larger lesion involving the left cheek, which was concealed by his beard. A third and much smaller lesion occupied the outer half of the right lower eyelid. His general condition at this time was fairly good, although his voice was hoarse and there was some cough and expectoration. Examination of the lungs revealed dulness and moist râles at the left apex. The lymphatic glands of the axilla and neck were enlarged.

The patient was put on increasing doses of potassium iodid, and for a time the local condition seemed to improve. In fact, the lesion on the right cheek disappeared, but promptly recurred.

After about a month in the hospital, the patient began to show evident signs of decline. He lost weight rapidly; his cough and hoarseness increased. In December, 1909, he developed an abscess at the right sternoclavicular articulation which was evacuated. The pus contained blastomycetes in large numbers. Another much larger abscess then appeared on the left elbow. The old lesion on the right elbow was, at this time, practically healed. In February, a retropharyngeal abscess developed and was evacuated. Repeated examinations of the sputum for tubercle bacilli and blastomycetes were negative.

During February and March, the patient continued to lose ground. He became bed-ridden, ran a septic temperature and finally died April 13.

Necropsy.—Unfortunately, a complete necropsy was not permitted but sufficient examination of the contents of the thorax and abdomen was allowed to establish the diagnosis of systemic blastomycosis.

At autopsy, which was performed by Dr. Warfield, the most striking lesions were found in the lungs. These organs were voluminous and dark purplish in color. The glands at the root were rather large, but not caseous. The lobes of the right lung were bound together by tags of adhesions but the pleura in general was not thickened. The cut surface of both lungs showed a grayish finely granular appearance and over it were scattered small nodules, one at the base of the right lung, being about 2 mm. in diameter. Similar nodules were found in the spleen and liver, giving the organs the appearance of being filled with miliary tubercles. This resemblance to tuberculosis is a very characteristic feature of the disease.

The microscopic appearance of the lesions in the lungs also closely resembled miliary tuberculosis. The sections showed miliary abscesses, surrounded by varying numbers of giant-cells. The necrotic centers of these abscesses, together with the giant-cells, contain many of the characteristic organisms of blastomycosis. Very similar lesions are also seen in the sections from the liver, and thus establish beyond a doubt the diagnosis of systemic blastomycosis.

One interesting feature of this case is the fact that although repeated and thorough search was made, the sputum never contained any of the organisms in spite of the very extensive involvement of the lungs and the presence of symptoms pointing to pulmonary involvement ante mortem.

In other respects, the case resembles very closely the majority of those thus far recorded. In all the cases in which an autopsy was done, thirteen in all, the lungs were found to be more or less extensively involved. In several cases the lung symptoms were the earliest noted.

This very general involvement of the lungs would suggest the possibility that the respiratory tract may have been the portal of entrance by which the organisms gained access to the body. The symptoms referable to the lungs, however, have been mild in nearly all the cases, especially during the early part of the disease. The physical findings have not pointed to extensive lung involvement except in a few of the cases toward the end. The symptoms have resembled closely those of tuberculosis, although usually less pronounced than in tuberculous changes of equal extent and severity. Blastomycetes have been demonstrated in the sputum in seven of the recorded cases.

Another common and very pronounced feature of all the cases has been the formation of multiple abscesses, resulting often in sinuses and chronic ulcers. Some have healed, leaving scars. These abscesses have varied in size from minute, almost microscopic lesions to cavities large enough to hold a liter of pus. The miliary abscesses have been found most commonly in the lungs and spleen. The larger ones may invade the joints and cause erosion and caries of the bones.

These larger abscesses may be divided for descriptive purposes into two groups, superficial and deep. The deeper abscesses are, as a rule, larger and have been recorded in the abdomen, thorax, in the psoas muscle, in the retropharyngeal tissue and about the kidney. There is one deep abscess on record from which a quart of pus was evacuated.

Accompanying the formation of multiple abscesses, there are the symptoms which are usual in chronic pyemia—irregular fever, malaise, loss of strength and emaciation.

One point of interest is that in spite of the fact that extensive suppuration has been present in all the cases, in only three has amyloid degeneration been recognized. Characteristic cutaneous lesions of blastomycosis have been present in nearly all of the cases. In a few, the superficial lesions have taken the form of abscesses and superficial ulcers.

The prognosis in cases of systemic blastomycosis is exceedingly unfavorable. Of the recorded cases, only four have recovered. The course of the disease is essentially chronic. Most of the cases have lasted from one to two and one-half years. Only six of the cases have terminated in less than six months. Death has resulted in most instances from gradual exhaustion, due to chronic suppuration or to general dissemination of the disease through the various organs and tissues of the body.

From this very unfavorable record of results, it may be assumed that the treatment of the disease is not very satisfactory. The only drug which appears to have any specific action on the disease is potassium iodid. The patients who have recovered have received it in large doses.

Locally, the lesions should be treated like those of the purely cutaneous form of the disease. One of the best local applications is 1 per cent. copper sulphate solution in conjunction with the use of the *x*-ray.

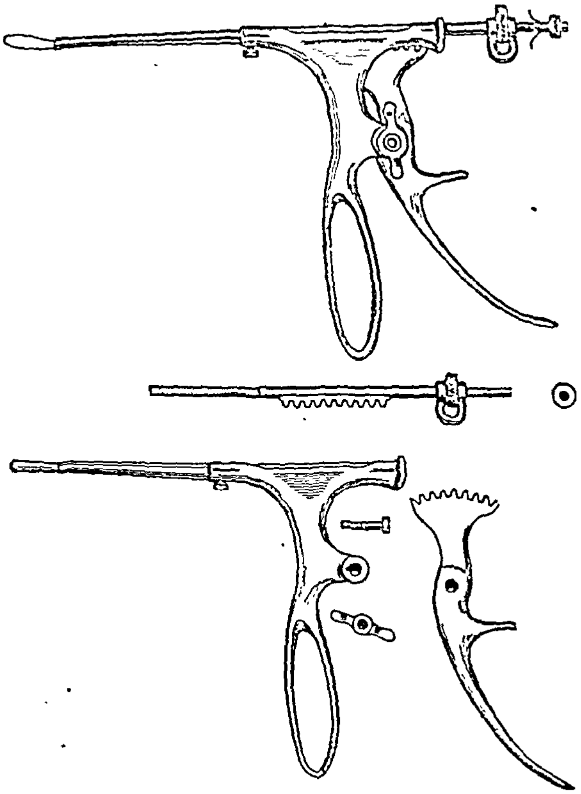
AN IMPROVED TONSIL SNARE

WILLIAM D. BLACK, M.D.
Ear, Nose and Throat Surgeon at Centenary, Osborne and City Hospitals
ST. LOUIS

The instrument and its various parts are so well shown in the illustrations that no further description is necessary. It is a more powerful instrument than the ordinary tonsil snare and does not get out of order like many others. It is simple in application, can be used a number of times without requiring a new wire, and, if properly adjusted, the wire cannot slip. It should be manipulated by a sort of forearm and wrist movement, instead of by the fingers, in closing it, so that the barrel will not be thrown out of line. It is made of solid brass with a heavy nickel coating. Number 7 or 8 piano wire should be used. I have used the instrument a number of times with excellent results. It is made by the O'Brien Worthen Co., Frisco Building, St. Louis.



W. Black's tonsil snare and its various parts.

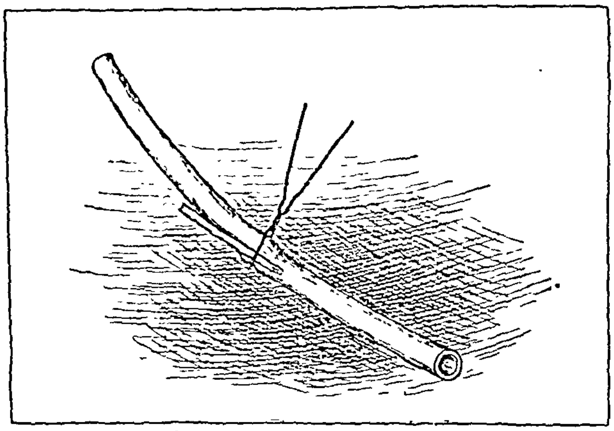
A SIMPLE DROP METHOD OF GIVING RECTAL ENEMAS OF NORMAL SALINE SOLUTION

JOHN EGERTON CANNADAY, M.D.
Surgeon to the Charleston General and McMillan Hospitals
CHARLESTON, W. VA.

Nurses in hospitals often experience a good deal of trouble in giving patients normal salt solution by rectum. For various reasons it becomes intolerable to the bowel and is expelled. Sometimes the solution is too hot, sometimes too cold, but the most frequent trouble is that it is allowed to run into the rectum too rapidly. The reasons for this are as a rule, first, that the nurse has no efficient means of making it flow drop by drop, and secondly, that the douche bag or container is usually hung too high and the water pressure is too great. The container should be hung so that the solution is 8 or 10 inches above the level of the rectum. It should frequently be tested by a bath thermometer and the temperature kept about 100 F. A hot-water bottle on either side of the douche bag or the frequent addition of small quantities of hot saline solution will serve to keep the temperature up.

I have found that the most simple means of inducing the fluid to flow drop by drop is not a hemostat but a hairpin and a match. When the hemostat is clamped on the tube it invariably begins to cut into the rubber and probably five minutes after the solution has been flowing drop by drop it is running in a steady stream. A much better, simpler method, and one which will issue a steady drop by drop flow as long as is desired, is provided for as follows: An ordinary wire hairpin is passed about the rubber tubing so that one of its prongs extends on either side; the free ends are secured from spreading apart by a twist of the wire with the fingers. Three or four wooden toothpicks or a match trimmed down to a wedge-shaped point are induced between the wire hairpin and the rubber tube and gently pushed in until the flow is just as desired. As a rule it is not wise to attempt to give too much fluid at a time. I find that in the average case about 6 or 10 ounces every hour and a half or two hours will be sufficient and will be a little less than the patient will tolerate comfortably. In giving saline solution regularly over a space of more than twenty-four hours one will find that more is usually absorbed at first than later after the system has been saturated with fluid.



Method of regulating flow in rectal enema.

A soft rubber catheter in the rectum is better borne and causes much less irritation, as a rule, than a rigid nozzle. If this catheter is made after the type of the usual retention catheter or if it is secured in place by a strip of adhesive plaster passed across the buttocks the patient is saved from the annoyance of frequent introduction and removal.

Aside from the well-known value of saline solution by rectum in the treatment of shock, thirst and hemorrhage, it is perhaps of greater value still in the prevention of urinary irritation and suppression. Usually the operative patient is depleted of water by purgation and gets but little fluid for several hours prior to, during, and after operation. A considerable amount of toxic and highly irritant material is thrown undiluted on the kidneys and they may prove unequal to the strain. If these toxic bodies are highly diluted with water their elimination will be felt far less.

VENEREAL PROPHYLAXIS IN THE UNITED STATES NAVY

ROBERT E. LEDBETTER, M.D.
Surgeon, U. S. Navy
CAVITE, P. I.

As the first requisites of a military or naval organization are health and efficiency, it is at once apparent that these two conditions must be maintained at the highest attainable point or disastrous results will ensue in time of war. The medical officers of the Navy are responsible for the physical condition of the personnel and it behooves them to safeguard this in every way possible.

One of the most recent steps toward this end is venereal prophylaxis, which is now in operation in the Navy, it having been officially adopted something over a year ago. Some of the naval medical officers, myself included, had recognized the value of the treatment, and were using it in some form or other, long before it was officially authorized. The method now used in the service is practically the same throughout, though there are, of course, slight variations, depending on the views of the several medical officers.

The treatment successfully employed at this station can be conveniently taken up and described under two heads, viz.: (1) preliminary instruction, and (2) application of the treatment.

PRELIMINARY INSTRUCTION

On reporting for duty at a naval station, or on board a ship, as soon as possible I begin a series of lectures to the men, which cover the entire subject of venereal disease. These lectures are couched in simple language, and the men are urged to ask questions, if they do not understand any part of the lectures. Particular stress is laid on the danger of neglecting or concealing real disease. Venereal prophylaxis is thoroughly ained to them, the excellent results obtained are ited, and they are urgently requested to cooperate with the medical officer in this important work. Most of them do so willingly, as the American bluejacket is very intelligent, and once he realizes that the treatment is for his well-being he cheerfully does his part. Of course there are a few "sea-lawyers" who consider the treatment a joke, or of no value, and these men are the principal sufferers, as, in addition to their greater liability to contract venereal disease, they are punished for not reporting for prophylactic treatment, or for concealing disease, as men of this class frequently do.

To be absolutely certain that no man escapes, each is furnished with a typewritten slip covering the salient points of the lectures and of venereal prophylaxis. At this station slips are made out in English, Spanish and Tagalog (the native language), as there are several hundred Filipinos enlisted in the native auxiliary force, and the majority of these men do not understand English. These notices are also posted in their sleeping-quarters, and in the navy yard boat office where they are on duty.

These lectures are repeated from time to time, as the personnel of the ship or station is constantly changing and many of the new recruits have had no instruction in venereal prophylaxis.

APPLICATION OF THE TREATMENT

At all naval stations, and when a ship is in port, a certain number of men are allowed shore leave every day. This leave is generally from about two o'clock in the afternoon, until seven or eight the next morning. A list of their names is kept and they are checked off when they go, and when they return from shore leave. The medical officer is furnished with a copy of this list every day when the men go ashore. As soon as a man returns from shore he is ordered to report at once to the sick-bay for prophylactic treatment. On reporting there his penis is examined, and he is interrogated as to whether or not he indulged in sexual intercourse while on leave. If he replies in the negative, he is excused from treatment, but if subsequently a venereal infection develops, he is punished for lying. It would be well to state here that all examinations are, if possible, conducted in private so as to spare the feelings of the man examined. If the man states that he had sexual intercourse on shore, he is given the following treatment:

The entire penis is scrubbed with liquid soap and water for several minutes, and then washed well with a solution of mercuric bichlorid 1 to 2000 in strength. If there are any abrasions present they are sprayed with hydrogen peroxid from a hand atomizer. The man is then placed in a sitting position, well forward in a chair in front of a convenient receptacle, and given two injections of a 10 per cent. solution of argyrol. He is required to retain each injection in the urethra for five minutes. After taking the injections, the entire penis is thoroughly anointed with a 33 per cent. calomel ointment. He is told not to urinate for at least two hours and to allow the ointment to remain on the penis for some hours. A temporary dressing is now put on the penis to protect his clothes and he is excused.

RESULTS OF TREATMENT

The results attending prophylactic treatment at this station have been most gratifying, in spite of the fact that at Cavite, unlike all other naval stations, no regular checking list is kept of men on leave, and there is no means of insuring prompt reporting, after return from shore leave. Before venereal prophylaxis was instituted here, the percentage of venereal diseases of all classes among the men averaged from 25 per cent. to 30 per cent. annually, and at times was even higher, as Cavite and vicinity are notorious for venereal diseases, especially syphilis and gonorrhea. The percentage of gonorrhea has been reduced to 8 per cent. annually, and this percentage includes about thirty patients that did not report for treatment. Chancroid was reduced from 5 per cent. to 2 per cent., which includes two patients not reporting for treatment. Syphilis has been reduced from about twenty cases annually, to one case for the entire year 1910, and this patient did not report for prophylactic treatment. These results speak for themselves, and show the efficacy of the treatment, if properly and conscientiously given.

CONCLUSIONS

After an experience of several years, it has been found that if men report for treatment within twelve hours after contact, the danger of contracting venereal disease is practically *nil*. After twelve hours, the treatment fails in many cases. It appears to be of special value in syphilitic contacts. I believe it to be an absolute preventive if employed early. The treatment, to succeed, must be given early and thoroughly. My percentages of failure of treatment have never been over 2 per cent. of cases and sometimes there are no failures for months at a time. The best drug for injections is argyrol, as it is non-irritating, and in my experience a more efficient germicide than any other drug used in the prevention of gonorrhea. I have tried protargol, but to be effective, it must be used in a 2 per cent. solution, which in many cases causes urethral pain and discomfort for some hours after taking the treatment, and this tends to keep many men from reporting, except under protest, as they would rather run the risk of infection than suffer the discomfort often caused by the injection of protargol. It is believed that if all contacts reported for treatment within twelve hours, venereal disease would soon be a negligible quantity in the service.

It would seem that venereal prophylaxis could be advantageously employed in civil practice, if physicians in civil life would impress its value on their patients. This would take time, but a few concrete examples in each locality would have a far-reaching effect, and the laity would, in my opinion, eventually see the value of this treatment and act accordingly.

SOME ETIOLOGIC FACTORS AND TREATMENT OF FURUNCULOSIS

H. K. GASKILL, M.D.
Assistant Dermatologist and Chief Clinical Assistant, Out-Patient Department Jefferson Medical College Hospital; Assistant Dermatologist, Philadelphia General Hospital
PHILADELPHIA

As the general practitioner is frequently called on to treat cases of furunculosis, he realizes that the march of progress in treatment has advanced along more scientific lines, and many are now using the serum therapy, which has been greatly modified, simplified and perfected since Wright wrote his first article advocating the use of staphylococcus vaccines in the treatment of this disease. They realize that it is not necessary either to allow it to run its course or to try every drug recommended by the dermatologist or therapeutist. In former years, it was common practice for the physician to prescribe "blood tonics," sulphur in large and nauseating doses, calx sulphurata or even to substitute baked egg shells for that preparation.

Ichthyol is often used externally in treatment of this condition, but its efficacy has never been proved and patients justly object to its use as it is extremely dirty and foul-smelling.

The average case of furunculosis, under proper antiseptic precautions against further crops, will cure itself in from one to four months, but many factors enter into the causation of the disease, and one should inquire carefully into the patient's habits, occupation and mode of living; of first importance must be considered an existing diabetes, nephritis or transitory albuminuria. Disorders of the gastro-intestinal tract play an important part in the etiology, as does excessive sweating, friction, lack of, or even excessive use of soap and water. Men who work in paraffin or bar metal workers and those who are thrown in close contact with potassium permanganate, potassium iodid and the bromids are frequently affected.

When single the lesions are usually due to some local injury as blows, friction or from pressure exerted, shown by those who have a sedentary occupation, as tailors, who often have a succession of single or multiple boils on the buttocks. Boils frequently follow various eruptive fevers, especially variola, septicemia, pyemia, sewer-gas poisoning and may occur as complications of certain skin diseases—scabies, eczema, etc. Severe strain and mental worry which lower the vitality must also be considered. Pressure of the collar button may cause a furuncle. In some men, if the back of the neck is shaved when the hair is cut, a crop of small boils will always ensue; this is undoubtedly due to the loss of the protection the hair normally affords, and as there are always present on the skin numbers of staphylococci, the collar rubs them directly into the mouths of the hair follicles, and sebaceous glands and pustules result.

A large number of so-called blood purifiers and blood tonics depend on potassium iodid for the effect, and as this drug frequently produces a pustular eruption, their use naturally is often disastrous.

The pain is out of proportion to the size of the lesion, is worse at night and is of a burning, throbbing character which can only be relieved by evacuation of the pus, leaving an indurated nodule, very tender and frequently accompanied by intense itching.

TREATMENT

First and always the urine should be carefully examined for albumin and sugar and the patient warned against any habits or occupations that might have an influence on the condition.

For furunculosis not caused by any constitutional condition, I have found the following line of treatment of great service in a long series of cases: The end of a wooden applicator is sharpened to a fine point, wrapped with a small piece of raw cotton and dipped into pure phenol. Many men prefer the use of the knife, but the "phenol stick" accomplishes the purpose; being slightly anesthetic, it is much less painful and the resulting scar is smaller, which is an important factor should the condition occur on the face. The phenol stick is inserted carefully where pointing occurs, held for a few seconds to allow the phenol to produce its anesthetic effects and then very gently pushed into the cavity. Extreme caution is used not to go beyond any resistance or the protecting barrier that has been formed to limit the process will be broken down or a blood-vessel punctured. After an opening has been made sufficiently large to permit of drainage the following ointment is applied:

℞

Acidi salicylici ....|	gr. xl vel lxxx
Petrolati ....|	℥i

Sig. Apply twice daily.

At the same time the first injection of staphylococcus vaccine should be given—100,000 to 1 c.c.; at the expiration of four days the second injection of 250,000, in one week more 1,000,000 and again in another week the same dose. In extreme cases, the succeeding doses may be one billion to 1 c.c., but this is rarely necessary. The injections are given into the loose cellular tissue between the scapulæ and better results can be obtained if a dry cup is applied for five minutes before each injection. It will be noticed that the swelling at the point of injection is much more quickly absorbed by this method through the increased amount of blood brought to the part. This also has the effect of preventing, to a great extent, the discomfort that usually occurs after the first injection, as there is some headache, a feeling of lassitude and a slight rise in temperature, rarely above 100 F. These symptoms do not occur after the second and subsequent injections, as a rule.

The question of autogenous versus stock vaccines is a mooted one. I have always used the latter, and my knowledge of the former is only derived from cases reported by other dermatologists. Very few men have either the time, facility or laboratory training to make their own vaccines. If they are obtaining better results than those who choose the easier, quicker and to my mind, the safer way, their reports do not show it. In the past year I have seen three cases in which unpleasant, if not worse effects have resulted. In two, a marked cellulitis occurred, in one case the swelling was opened on a diagnosis of abscess, but no pus was found. In another case, after five injections of autogenous vaccine a carbuncle occurred and was treated surgically.

By referring to the histories of patients both in private practice and at the dermatologic department of the Jefferson College Hospital, I found a long series of cases that have been treated as outlined in the preceding—opened with the "phenol stick," dressed with salicylic acid ointment and staphylococcus polyvalent stock vaccine injected. A few histories follow.

Case 1.—A. B., dentist, aged 32, was in good general health, except for furunculosis, and the urine showed nothing abnormal. One and a half years ago he infected his finger while working on a patient. In the course of fifteen months he had between twenty-five and thirty furuncles in different parts of the body, some almost carbuncular, all of which were opened by the knife and dressed, but no other treatment was given for the first six months. At the expiration of this time he was given autogenous vaccine, four injections during one month, with little improvement and in a few days after the fifth injection a carbuncle formed and was freely excised, leaving a large scar. He stopped this line of treatment and continued to have one boil after another until three months ago when I advised the above treatment. After the first injection he noticed a temperature of 99.6 F. and some discomfort. After the second injection of 250,000, marked improvement was noticed in the degree of induration and in the absorption. The dose was rapidly increased to one billion to 1 c.c., repeated twice, and then dropped to one million and the man is now apparently perfectly well. In all, he was given fourteen injections, the largest number I have ever given to one patient.

Case 2.—T. P. B., male, aged 64, a merchant, was first treated for eczema of the face and neck. Urine showed no albumin at that time. When this condition had been cured der local and internal treatment, the latter being directed inst constipation, the patient developed three boils on the ck of the neck and the urine showed a trace of albumin but no casts then or later. The furuncles were opened with the "phenol stick" but no vaccine given until a felon appeared on the index finger of the right hand. This was opened with the knife and the first injection given the same day. Subsequent to the second injection, four days later, the improvement was very apparent, and after a total of six injections, the last four of one million to 1 c.c., the condition was cured and there has been no recurrence.

Case 3.—E. M. K., aged 27, salesman, had had four or five furuncles on the back of the neck during the preceding three or four weeks and he noticed that they started just after his neck had been shaved. The treatment consisted in opening with phenol stick, application of salicylic acid ointment and six injections of staphylococcus vaccine. The man has had no further trouble.

Case 4.—R. V., aged 30, female, for several months had been having a series of boils on both forearms. Urine examination was negative. This patient was treated as were all the others and required only four injections to effect a cure.

In addition to the four cases mentioned I have the records of forty-six others that differ only in the variation of the situation and the severity of the condition. The patients all received the same treatment, the number of injections varying from four to eight and in each case a cure was effected.

In none of these cases has the index been recorded at any time during the course of the disease, the treatment being guided entirely by the clinical manifestations. This may not be a strictly scientific means of procedure, but it is what the busy general practitioner must do and he is handling a remedy from which the risk is very remote.

CONCLUSIONS

Furunculosis showing no causative factor in any kidney complication can be successfully treated by being opened with a sharpened cotton applicator dipped in phenol, with injections of polyvalent staphylococcus vaccines and by applications of salicylic acid ointment from 5 to 15 per cent. strength.

The inability of the physician to prepare autogenous vaccines on account of lack of time, laboratory facilities and experience makes the stock vaccines prepared by reliable firms a much more desirable method of procedure in the average case.

The pain on opening a furuncle is much less than with the knife as phenol is slightly anesthetic.

The reaction is very slight after the first injection and is lessened by use of the dry cup.

It is not necessary to record the index, the dose may be regulated by the clinical manifestations.

2030 Chestnut Street.

AN EPIDEMIC OF TYPHOID FEVER WITH ISOLATION OF B. TYPHOSUS AND B. COLI FROM THE WATER-SUPPLY

J. P. SIMONDS, M.D.
Superintendent, Bacteriological Laboratory, Indiana State Board of Health
INDIANAPOLIS

During April and May, 1910, an extensive epidemic of typhoid fever occurred among the inmates and officers of the Indiana Reform School for Boys at Plainfield. There were slightly less than 700 boys in the school at the time the epidemic occurred and ninety-one of them had typhoid fever. Nine other cases occurred in the families of the officers of the school. At least two persons who visited the institution at about the time the first case was reported are known to have developed the disease within three weeks after their visit. Among the 102 cases there were only two deaths, both deaths of boys who were members of the school.

Dr. Ernest Cooper, attending physician to the school, very kindly furnished me with a list of all the patients, with the date of onset of the disease in each case. The first patient, the superintendent's stenographer, was taken ill April 9. The second case appeared April 15 and the third on the eighteenth. From April 20 to May 11, one or more cases were reported every day, with the exception of April 25. The maximum was reached on April 29, when twelve new cases were received into the hospital. The next highest number for one day was eight cases on May 3. After May 11 the number fluctuated, but averaged about one case a day until May 24, when the last one came to the hospital. The number of cases received each day is shown in Chart 1.

The boys in the school are divided into twelve companies. Each company occupies a separate building, which is used as school-room and dormitory. All the inmates of the institution eat in a common dining-room, except the members of Company 12. The food of these boys is prepared in the common kitchen and is carried to the dining-room in the company's building. The boys are given milk two or three times a week.

Each boy spends a certain number of hours every day in school; the remainder of the time he works at whatever task he is detailed to do. Cases of typhoid occurred in every company, Companies 1, 2 and 6 being most affected, Company 10 least so. The number of cases in each company is shown in Table 1.

TABLE 1.—SHOWING NUMBER OF CASES OF TYPHOID FEVER AMONG MEMBERS OF EACH COMPANY

Company	Case No.	Company	Case No.
1	12	9	4
2	12	10	2
3	6	11	8
4	3	12	9
5	5	Officers and their families	9
6	12	Visitors	2
7	9		
8	8	Total	102

A sanitary survey of the institution was made May 2. The general situation was first examined and three important facts discovered, viz.: 1. Cases of typhoid fever occurred in the families of the officers of the school as well as among the boys. 2. The only things which the boys and the officers' families used in common were milk, and water from a spring, always designated as the "Big Spring," which was the main source of drinking-water for the entire institution. 3. It was also found that cases occurred in every company in the school, but that Company 10 had escaped with only two cases. On further inquiry it was learned that the boys of Company 10 used milk from the same source as the other companies, but obtained distilled water from the ice-plant for drinking-purposes. The two typhoid patients from this company, on being questioned, stated that they had been working away from their own company and had drunk water from various sources, including the Big Spring.

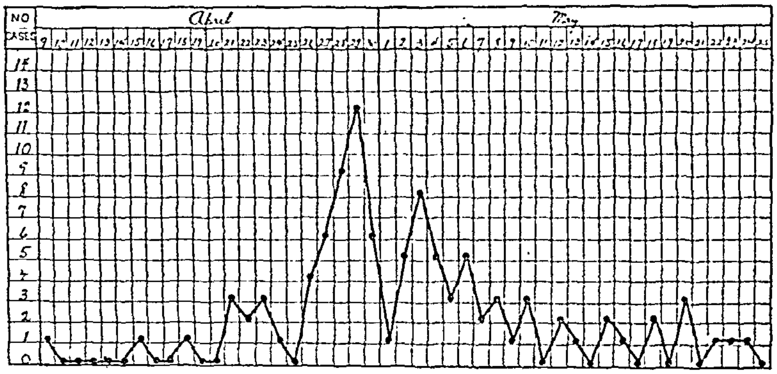


Chart 1.—Curve showing the occurrence of the cases during the epidemic.

Sanitary conditions in the dairy barn, milk-house, kitchen, bakery and ice-plant were found to be excellent. In the basement of each company building there are a number of shower baths, the water coming from a large open concrete reservoir. The water of this reservoir comes from two sources: at least one-half flows through a narrow chute from a pond or small lake which is fed by numerous springs; the remainder is pumped from a creek nearly half a mile distant. The pumping station on the creek was located, at this time, about one hundred yards below the outlet from a septic tank into which the sewage from eleven buildings was conducted. Later, the outlet from the septic tank was changed so as to empty into the creek several hundred yards below the pumping station. Water from the reservoir was examined bacteriologically a number of times. On May 2, when the creek was high as the result of a recent rain, the water in the reservoir yielded 30 per cent. gas in dextrose broth. At no other time did it yield more than 15 per cent., and once it yielded none.

The water-supply of the institution had for years come from a number of natural springs. Less than two years before the epidemic occurred the largest of these springs, always designated as the Big Spring, had been followed for some distance toward its head to the end of a series of jointed tiles put in position years before. From the end of the line of tile an iron pipe was laid to the former outlet of the spring (Chart 2). This pipe passed immediately beneath the toilet and sewer connection of the building occupied by Company 11, but all joints were carefully leaded and there was probably no leakage.

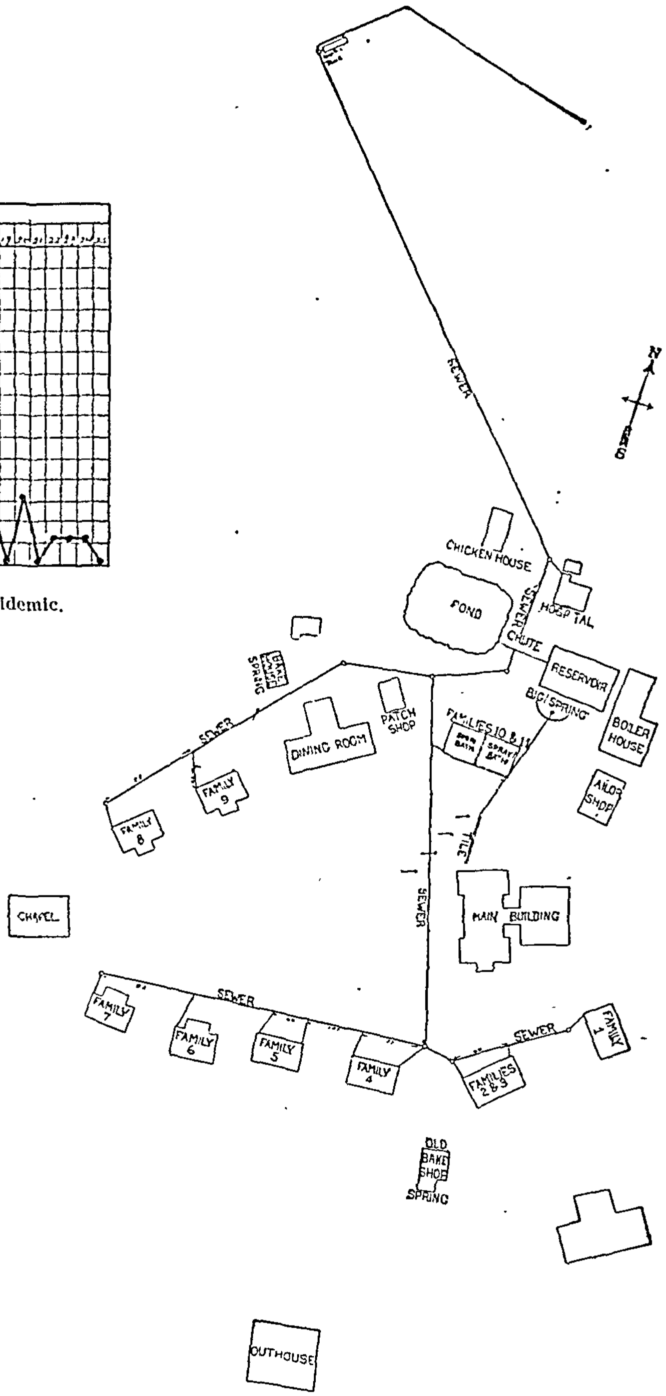

Chart 2.—Plan of the institution grounds, showing the location of buildings, dormitories, sources of water-supply, sewer system, etc.

In addition to this Big Spring, there was another in the basement of the bake-house which furnished water for cooling the milk and much of that used in the bakery, and in the dining-room and kitchen. A third spring, known as the Old Bake-shop Spring, half of the grounds and was not used except when some of the boys in near-by company buildings surreptitiously got water there to avoid carrying it the greater distance from the Big Spring.

The main sewer-line of the institution runs northward near the center of the grounds. The Bake-House Spring is west of the main sewer-line, the side from which the flow in the spring comes. A branch sewer, however, runs just south of it and in a position which favors contamination. The Old Bake-House Spring is south of the whole system of sewers. The tile which conducts the water of the Big Spring runs nearly parallel to the main sewer-line at approximately the same depth and within 15 or 20 feet of it. The upper end of the tile is probably somewhat nearer the sewer. After the Big Spring had been virtually proved to be the source of the infection, it was learned that when the sewer was laid nine years before, the engineers had great difficulty for a distance of 50 or 60 feet on account of the abundance of water in the sand in which the sewer was placed. This 50 or 60 feet was exactly opposite where the tile pipe of the Big Spring now is and the flow of water in the sand was noted to be toward this spring. The sewer was made of 12-inch salt-glazed tile, the joints of which were cemented. It is quite evident, then, that the water flowing from the Big Spring percolated around the main sewer of the institution, and that this condition of affairs had existed for nine years without any untoward results.

About March 15, the sewers were flushed out for the first time in several months, and considerable force was used. This was about three weeks before the first case of typhoid occurred.

A systematic bacteriologic examination of all the water used at the institution was undertaken. The results of the fermentation tests are shown in Table 2.

ABLE 2.—SHOWING RESULTS OF FERMENTATION TESTS *

Source of Sample	Percentage of Gas from Samples on Different Days									
	4/29	5/2	5/7	5/9	5/10	5/11	5/20	5/20	5/20	5/21
Big Spring	0	25	0	30	0	15	0	0	0	42
Pond	0	18	..	..	..	..	..	..	..	..
Reservoir	0	30	15	..	..	..	..	..	..	..
Bake-House Spring	0	0	10	..	..	..	..	..	..	..
Inlet to reservoir (creek water)		15	12	..	..	..	..	..	..	..
Old Bake-House Spring		..	30	..	..	..	..	..	..	..
Old tunnel		..	..	..	..	..	2	0	0	30

* Water from the "old tunnel" is from the same original source as that in the "Big Spring." The sewers were flushed out on the mornings of May 2, 10 and 20; the samples were taken in the late afternoon of May 2 and 10. Those examined on May 20 were taken at 6 a. m., 12 m. and 6 p. m., respectively, and on May 21 at 6 a. m. The spaces left blank *indicate that no specimen* was taken from that source on that date.

April 29, a sample of water from the Big Spring gave no gas when inoculated into sugar broth. On the morning of May 2, the sewers were flushed out. A sample of water taken late in the afternoon of that day gave a very suspicious gas test. Samples taken on May 20, yielded no gas. On that day the sewers were again flushed and a sample taken at 6 a. m., May 21, gave 42 per cent. gas.

No attempt was made to make accurate bacteriologic counts after the first examination. Each specimen was first plated on malachite-green agar. The forty-eight-hour growth on this media was washed off with sterile salt solution and suitable dilutions plated on Endo's medium. May 2 and 21, red colonies, which were proved by cultural tests to be *B. coli*, were isolated from the water of the Big Spring. May 2, an organism having all the cultural characteristics of *B. typhosus* and agglutinating with serum from one of the patients in a dilution of 1 to 50, was also isolated from the same source. This patient's serum gave a strongly positive agglutination test with a known culture of typhoid bacillus.

April 21, the boys were warned not to drink water from the Big Spring. How thoroughly this warning was obeyed is not known. About May 5, the Big Spring was sealed up so that no water could be obtained from it and the epidemic began at once to subside, the last patient entering the hospital May 24. The water-supply of the institution is now obtained from deep driven wells.

This investigation is interesting for the following reasons:

1. The close relation which had existed between the main sewer line and the chief water-supply of the institution for nine years without untoward results.
2. The evident relation between the flushing of the sewers and the amount of contamination in the water of the Big Spring.
3. The actual isolation of *B. coli* and *B. typhosus* from the water of this spring. The isolation of the latter organism from water is dependent largely either on luck or on an unusually heavy contamination. It was probably a combination of the two factors that brought success in this instance.

A RATIONAL INDICATION FOR BACTERIAL VACCINE IN TYPHOID FEVER

WITH A REPORT OF FOURTEEN CASES

JOHN P. FLETCHER, M.D.
First Lieutenant, Medical Corps, U. S. Army
WASHINGTON, D. C.

In the introduction to the study of infectious diseases. under the heading "Fever," Osler's "Modern Medicine" (Volume 2) says:

> The fever type is clearly associated, also, with the production of specific antimicrobic substances. In recurrent fever, the fall in temperature has been shown by Gabritschewski to be associated with the appearance of antibacterial substances that check the development of the spirilla; as these substances diminish, a new attack sets in. There is reason to believe that the fall of temperature with the crisis in pneumonia depends upon the somewhat sudden development of pneumococcidal and other reactions, because the pneumococci disappear, as a rule, from the circulating blood as crisis comes on.

This is quoted merely because it expresses broadly the general principle, which it is the purpose of this article to limit to typhoid fever, as the basis of a rational justification of vaccine therapy in this disease.

To go one step further, I may say that recovery from any infectious disease depends on two factors—the destruction of the causative organisms present in the body, and the elimination or neutralization of the toxins produced by them. With this as a working basis, a typical case of typhoid fever in a non-immune may be considered from its onset to a favorable termination with reference to these two factors alone, ignoring the well-known pathologic anatomy. Every non-immune or normal person must possess cell-receptors capable of combination with typhoid toxin, in order to present the typical symptoms of the disease. He must also possess either opsonin capable of actuating phagocytosis of the typhoid bacillus, or a bacteriolysin or agglutinin capable of accomplishing its destruction. In other words, a man who presents toxic symptoms as a result of typhoid infection, has killed enough bacilli to liberate their endotoxin. Let us follow this process.

Our subject secures a good dose of virulent typhoid bacilli. The first thing that happens is the destruction of a few of these organisms by the natural bacteriolytic forces, possessed by all individuals, with the liberation of their endotoxin. To this endotoxin the body reacts, producing a rise in temperature—very slight at first, because the dose of toxin liberated is small, on account of the feeble bacteriolytic power of the body. This toxin, besides causing a febrile reaction, excites the formation of a specific antibody to it and an antitoxin is produced, which, as it "fixes" the toxin present, causes a subsidence of the fever. If all of the bacilli of the initial infection were killed in one lot, our case of typhoid would end here. Unfortunately this does not occur. The infecting dose of organisms being more than the feeble natural defenses of the body can handle, they multiply rapidly, and if, on the other hand, body defenses were exhausted with the killing of the first lot and not reproduced, their rapid increase would result in mechanically obstructing the circulation. Fortunately, however, this also does not occur; for, besides the liberation of the endotoxin from within the cell capsules of the destroyed bacilli, substances exciting the production of both agglutinin and bacteriolysin are also liberated and the body is thus enabled to reproduce its antibacterial forces and attack the descendants of the unkilled bacilli of the initial infecting dose. The gradually rising temperature in the first week, then, may be said to be due to increasing doses of typhoid endotoxin liberated as the result of the destruction of increasing numbers of bacilli, by an ever-increasing bacteriolytic agent.

During the second week the condition reaches nearly a balance; that is, the production of antitoxin occurs nearly as rapidly as the toxin is liberated, but just enough later, or in insufficient quantity, so that the temperature remains practically uniformly high, on account of the abundance of bacteria from which the toxin is derived. During the third week, however, the bacteriolytic forces, which have constantly been added to, begin to assert themselves, and, either on account of their increased power, or a diminution in the virulence of the organism, the available supply of bacteria for the liberation of toxin diminishes. The doses of toxin then, after each bactericidal onslaught, are not so large nor so rapidly produced, in consequence of which, antitoxic action becomes more apparent. A dose of toxin produces a febrile reaction, which disappears as the toxin is neutralized; the temperature rises and then falls before another dose of toxin is produced to repeat the reaction; a remittent temperature results in which the reactionary rises have a tendency to become progressively less pronounced and the periods of remission progressively longer. The temperature therefore falls by lysis.

It will thus be seen that, during the third week, bacterial aggressiveness may be, figuratively, placed in one pan of a balance and the body defenses, consisting of bacteriolysin, agglutinin and antitoxin, in the other, the remittent temperature registering the tilting of the balance arm. The destruction of a group of bacilli and the liberation of their toxin are indicated by a rise in temperature, and the antitoxic action by a fall.

If the above paragraphs may be considered as detailing the toxin-antitoxin strife as it occurs, it is obvious that the introduction of any factor which would increase antitoxin formation would minimize the toxic symptoms of the disease; while the introduction of any factor which would increase bacteriolysis or agglutination would hasten its subsidence. Both of these conditions are fulfilled when dead typhoid bacilli are introduced into the body, in that the endotoxin is supplied without the necessary destruction of bacilli by the body, and the antitoxin, the formation of which it excites, produced in excess of that needed to neutralize it, becomes available to act on toxin produced from bacteria killed within the body; also the bacteriolysins and agglutinins, whose formation the dead bacilli have excited, are ready to act at once on living bacilli in the tissues.

That this does occur when antityphoid vaccine is used prophylactically is experimentally proved; and that the use of bacterial vaccine in clinical typhoid will start a prevailing tilt of the balance in favor of recovery, from the observation of several cases I cannot help but believe. In fact, as the cases herewith reported show, the duration of fever in the majority was below the average, while the average in all cases was materially reduced. In no case in which vaccine was administered did untoward symptoms follow, aside from the expected reactionary temperature rise; and even in cases not showing a decided result, the patients professed to feel stronger and better, and even asked that the dose be repeated.

A brief outline of fourteen cases of typhoid occurring in 1910, in which the vaccine was used therapeutically, after a positive diagnosis, is as follows:

Case 1.—The patient was admitted August 9; Widal positive August 21; patient inoculated August 26 with 500,000,000 bacteria; no reaction after inoculation. Temperature fell to normal within seventy-two hours; remained normal forty-eight hours; then the patient had a typical relapse lasting three days. The fever including relapse lasted eighteen days. Recovery ensued.

Case 2.—The patient was admitted August 11; Widal positive August 21; patient inoculated August 26 with 500,000,000 bacteria. The inoculation was followed by a sharp rise in temperature to 104.5 F. which responded to an ice bath. Thirty-six hours later it reached normal and remained there. This patient was severely prostrated; was in coma-vigil when inoculated. The symptoms abated as rapidly as the fever and in three days the patient was begging for beefsteak. The fever lasted nineteen days. The patient recovered.

Case 3.—The patient was admitted August 14; Widal positive August 23; patient inoculated August 26 with 500,000,000 bacteria, and again on September 6 with 1,000,000,000 bacteria. The patient was all but abandoned as hopeless on two occasions following prodigious intestinal hemorrhages. There was no temperature reaction following either inoculation, but a decided clearing of the mental haze was apparent. The total duration of fever was thirty-two days. Recovery ensued.

Case 4.—The patient was admitted August 15; Widal positive August 22. The patient was inoculated August 26 with 500,000,000 bacteria. The patient appeared moribund at time of inoculation; could not be roused and could not swallow nourishment. Urine and feces were evacuated involuntarily; very slight reaction followed injection. Within seventy-two hours the temperature was normal and a most startling improvement in every way was apparent. A second rise of temperature lasting forty-eight hours, after three days of normal temperature, was found to be due to an otitis media; paracentesis relieved it almost immediately. There were fourteen days of fever, exclusive of that due to otitis. The patient recovered.

Case 5.—The patient was admitted August 15; Widal positive September 1; patient inoculated September 12 with 500,000,000 bacteria. This was a very mild case and several Widals were necessary to diagnose typhoid fever as complicating an acute bronchitis, which was present. Convalescence was well established when the patient was suddenly seized with a coughing fit and died in an hour of cerebral embolism.

Case 6.—The patient was admitted August 17; Widal positive August 23; patient inoculated September 6 with 500,000,000 bacteria, and again September 16 with 1,000,000,000 bacteria. No marked reaction followed either dose, though marked symptomatic improvement was apparent after each. After thirty days of fever the temperature fell to normal, remained so for two days, then rose to 102 following a chill and returned to normal within eight hours. This was repeated twice on two succeeding days, after which there were three days of normal temperature, and again three days of chill and fever. There was no history of malaria for over three years previously, but during the second set of chills a quartan plasmodium was found; the hypothesis being a triple quartan infection latent or by parthenogenesis. The case responded readily to quinin. Recovery followed.

Case 7.—The patient was admitted October 12 with tonsillitis. Temperature continued elevated after subsidence of throat symptoms. Widal positive November 6. The patient was inoculated Nov. 9 with 500,000,000 bacteria, and November 19 with 1,000,000,000 bacteria. The duration of fever, including severe relapse, was thirty-two days. The patient recovered.

Case 8.—The patient was admitted October 26; Widal positive November 6; patient inoculated November 9 with 500,000,000 bacteria; died November 19, after three days of continuous, profuse intestinal hemorrhage.

Case 9.—The patient was admitted October 27; Widal positive November 7; patient inoculated November 9 with 500,000,000 bacteria, and November 19 with 1,000,000,000 bacteria. At the time of the first inoculation the patient was comatose; some improvement in symptoms followed the first dose, though complete aphonia persisted several days after second dose. Duration of fever twenty-eight days. Recovery.

Case 10.—Patient admitted November 2; Widal positive November 15; patient inoculated November 15 with 500,000,000 bacteria. Duration of fever seventeen days. Recovery.

Case 11.—Patient admitted November 5; Widal positive November 15; patient inoculated November 15 with 500,000,000 bacteria. Duration of fever sixteen days. Recovery.

Case 12.—Patient admitted November 6; Widal positive November 15; patient inoculated November 15 with 500,000,000 bacteria. Duration of fever eighteen days. Recovery.

Case 13.—Patient admitted November 12 from suspect ward. Widal positive November 15; patient inoculated November 15 with 500,000,000 bacteria. Duration of fever ten days. Recovery.

Case 14.—Patient admitted November 12 from suspect ward. Widal positive November 15; patient inoculated November 15 with 500,000,000 bacteria. Duration of fever eighteen days. Recovery.

In the foregoing cases the diagnosis was based on the Widal reaction, the macroscopic method being used and the end titer of each patient's serum being obtained. Besides the Widal reaction, total leukocyte counts and differential counts were made on the same day as the Widal.

In no case was actual or polymorphonuclear leukocytosis present. The feces of each was plated on Endo's medium; all suspicious colonies were fished and planted in lactose-litmus agar. From these tubes, showing a characteristic reaction, the organism was transferred to plain agar, and as a plain agar culture, was agglutinated by a known typhoid immune serum.

It was noticed distinctly that the cases which gave the lowest serum titer in the Widal reaction were those in which the symptoms were most aggravated. On the other hand, the cases which gave an agglutination in a dilution of from 1:360 to 1:720 on the tenth day, ran a mild, short course. With the exception of three of the cases cited above, and five ambulant cases, which have not been reported, the degree of prostration and toxemia manifested by these patients within ten days of their admission was the most pronounced that I have witnessed in several typhoid epidemics. The contrast following a single inoculation was consequently most remarkable. In Cases 3, 5, and 7 the result was most startling. The entire picture was changed in forty-eight hours from that of a man whom the nurses were expecting to carry out any minute, to that of a patient distinctly able to take notice.

In conclusion it may be said that the therapeutic administration of antityphoid vaccine is attended with no bad results and does in no way increase the patient's discomfort. On the other hand, its use did, in all of the cases observed, improve the general condition of the patient; while in the three cases above referred to, its action was nothing short of marvelous. In view of these facts, and granting the correctness of the hypothesis advanced above, it would seem that vaccine in typhoid fever is certainly rationally indicated.

RESECTION OF THE SPERMATIC PLEXUS FOR THE RELIEF OF CERTAIN FORMS OF DYSMENORRHEA *

M. L. HARRIS, M.D.
CHICAGO

Dysmenorrhea, or painful menstruation, is the bane of many a woman's life. To be obliged to keep in bed swathed in hot cloths and stupefied with drugs for from a day or two to a week or two out of every month is sufficient to drive almost any woman to distraction, yet such is the unfortunate lot of many.

The cause of the pain in these cases has been the subject of much discussion and the most divergent views have been expressed concerning it. Some writers hold that the pain is due entirely to local conditions of the pelvic organs, while others assert that local conditions have little or nothing to do with producing the pain, but that it is always the result of some general disturbance.

Theilhaber[1] says that only in a minority of the cases is the pain due to anatomic causes, while in more than three-fourths of the cases it is the result of functional disturbances. He believes that the pain is caused by a spastic contraction of the smooth muscle fibers forming the sphincter of the internal os uteri and has devised a special knife for cutting out a section of this sphincter.

Menge[2] divides the dysmenorrheics into two classes: those with hypersensitive nervous systems and normal pelvic organs—idiopathic dysmenorrhea; and those with hypersensitive pelvic organs and normal nervous systems—secondary dysmenorrhea; but he says that these two forms present such similarities that in their nature they must be related. He recognizes this relationship by stating that all dysmenorrheas must be referred to a "menstrual painfulness of the uterus," which practically amounts to saying that the patient has dysmenorrhea because she has painful menstruation.

It seems to me that there can be no disputing the fact that abnormal local conditions may cause pain during menstruation; likewise, that in neurotic or hysterical women, or in women with unbalanced or temporarily deranged nervous systems, the performance of a function such as menstruation may give rise to pain, which under similar conditions in women, with healthy, stable nervous system, would scarcely be felt.

---

* Read before the North Texas District Medical Society, Dec. 14, 1910.

1. Centralbl. f. Gynäk., xxv, 1339.
2. Centralbl. f. Gynäk., xxv, 1367.

Menstruation is not a simple function but a very complex one in the performance of which are concerned, not only the general conditions of the body as a whole, but also the local condition of three organs, namely, the ovaries, the tubes and the uterus.

If general states of the body are instrumental in producing menstruation, derangements of these general states may produce deranged menstruation. If the ovaries, the tubes and the uterus take part in the function of menstruation, abnormal conditions of these organs may cause abnormal menstruation.

Based on the location of the cause, then, we may subdivide the dysmenorrheas into three groups: (a) those due to deranged general states; (b) those due to abnormal conditions of the uterus; (c) those due to abnormal conditions of the ovaries and tubes.

As will be seen, the ovaries and tubes are grouped together. The reason for this is that the inner three-fourths of the tubes and the ovaries have the same nerve supply, and painful sensations arising from them cannot, therefore, be differentiated.

It is not my intention to take up in detail the various pathologic conditions found under these three groups, but it is to the third or tubo-ovarian group that attention will be directed. Furthermore, it is not so much my desire to define the particular disease or pathologic condition giving rise to the pain as it is to establish the fact that the condition, be it what it may, may be confined to the ovaries or to the inner portion of the tubes or to both.

The lesions found are of two kinds: gross pathologic lesions such as ovarian or tubal abscesses or large ovarian cysts, and rather inconspicuous lesions such as the angiodystrophies of the ovaries, chronic interstitial salpingitis, and adhesions of the ovaries or tubes to the intestine, omentum or neighboring peritoneal surfaces.

It is the latter class, or the inconspicuous lesions that are responsible for the pain in that variety of dysmenorrhea called ovarian. I am aware that many writers have denied the existence of the so-called ovarian dysmenorrhea, but I am convinced that they are mistaken.

I think that all physicians of experience in this line will recognize a class of women who suffer intensely at the menstrual period, yet in whom the most careful examination fails to discover any general state or any disease of the uterus sufficient to account for the pain. These patients are frequently unmarried and often have had the dysmenorrhea throughout their entire menstrual life. Others are married and have borne children without any material change in the dysmenorrhea.

A characteristic feature of the pain is that it is mostly premenstrual, that is, it precedes the flow by from one or two days to a week and gradually subsides as the flow becomes established. The pain is usually bilateral, referred to the ovarian region or the lower abdomen. It may extend down the inner side of the thighs or the outer side over the hips and is so severe that most of the patients are confined to bed for a variable time each month. The ovarian regions are very sensitive on pressure. The women are frequently neurotics or have hypersensitive nervous systems, either primarily or become so by reason of the repeated suffering, and are the ones who resort to all kinds of anodynes, narcotics, headache powders, hot whiskey and gin drinking, etc., to secure relief from the pain. About the only thing discovered on examination is tenderness in the region of the ovaries, sometimes excruciating, which becomes more marked the nearer the time is to the next menstrual period.

It was in hope of relieving these patients that I conceived and carried out the idea of resecting the nerves which supply the ovary. These nerves, according to Nagel in von Bardeleben's "Handbluch der Anatomie des Menschen," arise from two sources: (1) from the plexus renalis; and (2) from the lower portion of the plexus aorticus abdominalis or, as Frankenhäuser calls it, the plexus spermaticus, and they are purely sympathetic in their nature.

As a rule, there are two spermatic ganglia situated on either side of the aorta just above the promontory of the sacrum.

The plexus renalis lies in the angle formed by the renal artery and the aorta. From this point is given off a thick trunk which accompanies the spermatic vessels and receives several small nerves from the spermatic ganglia. These nerves, called the spermatic plexus or the plexus arteriæ ovaricæ, pass along with the spermatic or ovarian vessels through the infundibulo-pelvic or suspensory ligament of the ovary into the pelvis and distribute branches to the broad ligament, the ovary and to the ampulla of the tube and form in conjunction with uterine nerves a small ganglion situated in the neighborhood of the uterine attachment of the ligamentum ovariæ proprium. The ovary and the tube as far as the isthmus are, therefore, supplied by the spermatic plexus, while the uterus and the isthmus of the tube receive their nerve supply from an entirely different source, namely, through the hypogastric plexus. It is very evident, then, that any pain-producing irritation, having its origin in the ovary, or in the tube, can be transmitted centrally only through the spermatic plexus just described and a resection of these nerves must effectually cut off all sensation in these parts. A resection of these nerves is a simple matter if they be approached at the upper part of the infundibulo-pelvic ligament where they lie rather closely together accompanying the ovarian vessels.

The abdomen is opened in the usual manner. The infundibulo-pelvic ligament picked up with a forceps and made taut. An incision 3 or 4 cm. in length is then made through the peritoneum along the free border of the ligament beginning well up toward its proximal end. With the handle of a scalpel or any blunt dissector the two layers of peritoneum are freed from all the other tissues forming the ligament; a catgut ligature is passed around the proximal end of this mass and tied; a similar ligature is passed around the distal end and the intervening portion, usually from 2 to 3 cm. in length, is resected. The incision along the free border of the ligament is then closed with catgut and the operation is completed.

It will be readily understood that in the small mass of tissues removed are included all the nerves passing to the ovary as well as the ovarian vessels from which it is impossible to separate them. As the ureter enters the pelvis through the base of the proximal portion of this ligament, great care must be exercised not to include it in the ligature. Of course the resection is made bilaterally if the trouble is bilateral.

As these nerves are the only ones supplying the ovaries and the inner end of the tubes the effect of resecting them is, of course, to render those parts anesthetic so that they can no longer give rise to painful sensations.

It will be readily understood that the operation here recommended affects only those cases in which the pain is of ovarian or tubal origin. It does not relieve the pain when it is due to pathologic conditions within the uterus and it is necessary, therefore, to diagnose the cases correctly, and to make a careful selection of those to which the operation is suited.

That a multiplicity of causes of the pain may be present is self-evident from what has been said, and when this is the case the other conditions must be remedied if possible by proper general treatment and local operative measures if relief from pain is to be expected.

I shall not now enter into a detailed report of the cases in which I have operated, but will simply say that I have operated on over twenty women with gratifying results. I have seen women, who had spent from several days to a week or more in bed at every menstrual period, menstruate without pain and recognize its presence only by the appearance of the flow. Other patients have lost only the acute premenstrual pain, while in a few no benefit has followed, evidently owing to the fact that the pain had its origin elsewhere than in the ovaries or tubes.

No other effect than the relief of pain has been noted as the sexual and reproductive functions are not interfered with.

A CONVENIENT METHOD OF TESTING THE VISUAL FIELDS FOR COLOR WITHOUT THE USE OF A PERIMETER

FOR APPLICATION IN CASES OF SUSPECTED INCREASED INTRACRANIAL TENSION

TOM A. WILLIAMS, M.B., C.M. (Edin.)
WASHINGTON, D. C.

It was formerly supposed that inversion of the visual fields for blue and red was pathognomonic of hysteria, especially when, in addition, a contraction of the field for form was present. Not everyone is yet acquainted with the work of Babinski,[1] which has clearly shown that the perimetric examinations of hysterical patients, as ordinarily conducted, are redolent of suggestions, and that these very often influence the patient; so that the findings are not reliable except as indices of suggestibility. Thus, there is no characteristic visual field type in hysteria.

There are certain affections, however, in which the visual field is characteristically inverted or interlaced. This happens whenever the intracranial tension is increased to the point where there is an interference with the functions of the neurons which conduct visual impressions. This manifests itself most particularly, clinically speaking, toward the periphery of the retina, where the sensibility is feeblest; so that, as Bordley and Cushing[2] have shown, the red is perceived even sooner than the blue on approaching the center of the visual field in cases in which the intracranial tension is increased by edema of the brain, whether this is produced by a tumor within the cranium, by hemorrhage therein, or by some constitutional condition resulting from chronic nephritis, diabetes or other modification of the blood.

To measure this inversion or interlacement of the color fields accurately, a perimeter is of course required; but I have found that the inversion may be ascertained roughly by the following method:

The patient sits with his back to a good light, looking fixedly at a point in the distance. He is directed to signal as soon as he perceives any movement of the examiner's hand. The visual field is then approached by the observer's hand, which holds alongside and parallel two objects, colored respectively an intense, pure, bright red and a blue. After the patient signals, he is asked to signal again as soon as he perceives any color, while the center of the field is very slowly approached. The observer then stops the movement, and asks what color is seen. For corroboration, the movement is then continued until the other color is also seen.

In normal persons, blue is always seen before red. If this is not the case, increased tension may be suspected. In two recent cases, one of tumor and one of albuminuric retinitis, this method has been as positive as that with the perimeter.

If the test is performed with careful technic, it is reliable, and is a useful addition to clinical methods. Indeed, Cushing believes that when inversion of visual fields appears in the case of a tumor, operation should not be further delayed.

A SIMPLE METHOD OF CULTIVATING THE MORAX-AXENFELD DIPLOBACILLUS *

WILLIAM H. PETERS, M.D.
CINCINNATI

This case report calls attention to the fact that the Morax-Axenfeld bacillus grows as readily and in as characteristic manner on Dorset's egg medium as on Loeffler's blood-serum. The comparative ease with which the former medium can be prepared should render this fact of value.

To cite an illustrative case:

Patient.—J. M. W., aged 34, a blacksmith, was admitted into the service of Dr. D. T. Vail on Oct. 24, 1910. He was suffering from double catarrhal conjunctivitis, which he thought had been acquired by using the towel of his roommate who had sore eyes.

Bacilli.—Smear preparations from the purulent secretion from each eye showed the presence of isolated diplobacilli lying between the polymorphonuclear leukocytes and apparently in pure culture. The diplobacilli measured 2.7 by 0.8 and the rods had rounded ends. They stained well with Loeffler's methylene-blue, but were decolorized by Gram's method. Slants of Dorset's egg medium and Loeffler's blood-serum were inoculated with pus from each eye. After twenty-four hours' incubation, numerous characteristically pitted colonies appeared resembling those described by Morax[1] and Pusey.[2]

The pits in Dorset's egg medium were not quite so deep and the diameter was less than those in Loeffler's blood-serum, and they did not become confluent on the former medium so rapidly as on the latter. Transplants failed to grow on the ordinary laboratory media.

Neurasthenia in Young Children.—A deficiency of nerve force may be present from earliest childhood, often as an accompaniment of the "neurotic" temperament, and occasionally with mental deficiency. Cases of this condition, which might be described as "neurasthenia minor," are generally the offspring of neurasthenic or neurotic parents, and may drift into more confirmed neurasthenia in later life.—C. Riviere, in the *Practitioner.*

Therapeutics

ANKYLOSTOMIASIS, UNCINARIASIS, OR HOOKWORM DISEASE

These terms may be regarded as practically synonymous. They are applied to a condition characterized by symptoms which are caused by the presence in the intestinal canal of the worms *Ankylostoma duodenale* and *Uncinaria duodenalis*, or *Uncinaria americana*, which, if not identical, at least closely resemble each other. They belong to the class of nematodes in which are included *Ascaris lumbricoides*, *Oxyuris vermicularis*, and trichinæ, all of which have recently been described in this department.

It has been comparatively recent that the economic importance and the frequency of the *Uncinaria duodenalis* has been recognized, although the symptoms produced by them have been considered a clinical entity for over a century. Early in the nineteenth century, a special form of anemia was recognized as affecting miners in Hungary. In 1838, Dubini found ankylostoma in the intestine of a girl who had died of progressive anemia. In 1851, Griesinger declared that this parasite was the cause of Egyptian chlorosis. But the clinical importance of the parasite was not definitely settled until, in 1882, Perroncito showed that the epidemic of so-called miners' anemia which occurred during the building of the St. Gothard tunnel was due to ankylostoma.

Since the occupation of Porto Rico by the Americans about twelve years ago, the disease has been thoroughly studied by American physicians, especially by Drs. Ashford, King, and Stiles. These men have proved the great prevalence of the disease not only in Porto Rico, but in the southern part of the United States; have pointed out its great industrial importance; and have demonstrated a simple and effective method of cure.

The male worm is about 11 mm. in length and about 0.5 mm. in width; the female is about 15 mm. in length and about 1 mm. broad. It is found most abundantly in the jejunum, but it may be found also in the duodenum and upper part of the ileum. It may be firmly attached to the mucous membrane, or may be imbedded in the mucus on the membrane, or may be free in the intestinal canal. The eggs are passed in large numbers with the feces, and under favorable conditions may retain their vitality for a long time. These favorable conditions include warmth, moisture and darkness. Sunshine and the incidental drying are destructive to them. After passing from the body of the host, especially when the soil is dry, they rapidly become scattered about.

Their most common attack on the human subject is through the feet. Both adults and children who run about barefooted in places where the disease is endemic suffer from a dermatitis which is caused by the action of the ova or eggs on the skin. They first produce a dermatitis and next an eruption of vesicles which are liable to be infected by various bacteria, producing pustules and ulcers of varying depth, which may persist for a long time, and which, when healed, usually leave discolorations. The ova pass through the skin and into the blood by which they are carried to the lungs. Here they escape into the bronchioles, migrate to the bronchi, thence to the larynx, and into the throat, from which they are swallowed.

The eruption caused by the ova and larvæ of the hookworm is known as "ground itch." It is possible that the disease may be brought on by the swallowing of the larvæ incidental to unclean habits, the food being infected by dirty hands, or by the drinking of water containing the larvæ, but it is commonly believed that the number of worms ingested in this way is very small, and it has been found that nearly all of the subjects of the disease have also been the victims of ground itch, therefore it is considered that this round-about route is the most common method of infection.

To those who live in the northern states it might seem that this is a subject of no practical importance and of very little interest. To those who live in the southern states where the disease is endemic it might seem that the disease is so common and so well known that it is not worth while for the physician to spend any time in reading or writing about it. To those who live on the borders of regions where the disease is endemic where occasional cases are likely to be seen, it certainly is of great importance to be familiar with the disease and the modern methods of treatment. To all physicians it is a matter of interest to know the symptoms which the disease presents, and how it may be cured.

It is common to describe three classes of cases: The mild cases are characterized by pain and uneasiness in the abdomen. These symptoms are commonly attributed to indigestion, and rather apt to be more prominent on the right side of the abdomen; they may be accompanied by tenderness in that region. The pains are sometimes increased and at other times relieved by taking food. The appetite in some cases is diminished, and in others is increased. There may be headache and dizziness, and there is usually indisposition to any exertion, either mental or physical.

In cases of moderate severity the pain in the abdomen may be more pronounced, and the headache is usually commoner and more severe. There is dizziness and often tinnitus aurium. The mucous membranes and the conjunctivæ are pale; the skin dry; the appetite impaired; and there may be nausea and vomiting. Breathlessness on exertion is common, and there may be palpitation. The patient complains of fatigue and indisposition to exertion, and there may be fever.

In the more severe and advanced cases the anemia is more striking; the patient presents a pallid appearance and the conjunctivæ may show an icteric tinge. Edema of the feet and ankles is common, and sometimes there is general anasarca. There may be extensive ascites. The palpitation of the heart is severe, and dyspnea, even on the slightest exertion, is considerable. The pulse is weak and compressible, and there may be pain in the precordial region. The dizziness and tinnitus are generally very troublesome. Dimness of sight is common, and the pupils may be dilated. Often there is sleeplessness. The muscles, though apparently plump and well-nourished, are weak, and the patient is absolutely unable to do anything. Often there is considerable fever, which is, as usual, higher in the afternoon.

The examination of the feces is of great importance, both from a diagnostic and a therapeutic point of view. While in regions where the disease is endemic the general symptoms, especially the anemia and the indisposition to exertion, may lead to a presumptive diagnosis which is generally correct, the only accurate diagnosis is based on finding the eggs or the worms in the feces, and these should be carefully examined in every suspected case. After the treatment has been carried out, the only way of definitely determining whether or not the cure is complete is by examining the fecal matter and determining the absence from it of both worms and eggs.

PROPHYLACTIC TREATMENT

The treatment may be considered under three heads. The prophylactic treatment is of great importance both to the individual and to the community. As has been stated, the disease is spread by neglect in providing for suitable disposal of the discharges from the rectum. In warm climates where the disease prevails among the poorer classes of society the methods of sewerage employed in cities are unknown, and the majority of people deposit their feces in whatever situation, in field or forest, they may happen to be when the desire comes on them. When sanitary legislation reaches the point that the transmission of infectious disease by the feces is almost impossible, there will be no further danger of the transmission of this disease to uninfected persons. This of course is an immense problem, but one which it seems likely will necessarily have to be met, even in country districts, sooner or later.

The second point in the prophylaxis is the prompt curing of all sufferers from the disease. When this has been accomplished, of course the necessity of the first will be less urgent, but the carrying out of one proposal is almost as difficult as the other, and the first proposition is the most important, because the improper care of the feces results in transmission not only of this disease, but also of several others.

The individual prophylaxis, to be observed by persons living in regions where the disease is endemic consists, in the first place, of protecting the feet and legs by wearing shoes which will keep the dirt and sand away from the skin. Of less importance, but still also to be observed are cleanliness of the hands, care in the preparation of food, and the avoidance of water which may be infected. This may be accomplished by using filtered, distilled, or boiled water.

MEDICINAL TREATMENT

Several drugs have been recommended in the treatment of this disease; the most important are turpentine, oil of eucalyptus, betanaphthol, and thymol. Of these the evidence is very strong that thymol is the most useful and safest, and is fairly entitled to be termed a specific. When this drug is used the patient should be prepared for the treatment by being compelled to fast during the greater part or the whole of the previous day. The previous night he should receive a sufficient dose of magnesium sulphate to produce several watery movements. In the morning, before food of any sort has been taken, the thymol may be administered. The dose may be divided into two or three parts, which may be taken at intervals of one or two hours. The whole amount administered in any one day should be 3.0 grams (45 grains). Two hours after the last dose, another dose of the sulphate of magnesium should be given. It will be found that the thymol, having attacked the worms, has either destroyed them, or at least lessened their vitality to such an extent that they have loosened their hold on the mucous membranes, and the final dose of the Epsom salt will carry them out of the intestine.

It is important that the intestine should be so far as possible empty when the drug is taken, and the preliminary dose of magnesium sulphate not only washes out the food debris, but also the mucus in the intestinal canal in which many of the worms are often imbedded. The action of the drug is desired on the worms in the canal, and it is in no way desirable, in fact it is undesirable, that the thymol should be absorbed. Consequently, no fatty food, alcohol or oil should be taken lest absorption be caused. Castor oil should not be given as a cathartic, although senna may be substituted for the sulphate of magnesium, but it is no better.

The treatment with thymol should be repeated at intervals of three or four days or a week. Stiles, who has given very explicit directions for the treatment of this disease, recommends that the treatment should be commenced on Saturday and carried out on Sunday, and that it should be repeated on successive Sundays until examination of the feces shows entire absence both of the eggs and of the worms.

Finally it remains to speak of the treatment of the results of the infection. It is surprising with what rapidity patients commence to improve after the worms have been removed by the use of thymol; however, the administration of iron will hasten the recovery from the anemia. No form of iron is more useful than the fresh Blaud pill (pilulæ ferri carbonatis) in a dose of 0.20 gram (3 grains) three times a day, after meals; or the reduced iron (ferrum reductum), in dry capsules, in dose of 0.10 gram (2 grains), three times a day, after meals; or the tincture of iron (tinctura ferri chlorid) in a dose of from 3 to 5 drops, in fresh lemonade or other sour mixture, three times a day, after meals; or the patient, if a young child, may be given an *Eisenzucher* tablet (saccharated iron oxid), each 3 grains, to chew up like candy, thrice daily, after meals.

The tincture of iron may be well ordered as follows:

℞	c.c.		
Tincturæ ferri chloridi	5		fl.ʒiss
Syrupi acidi citrici	25	or	fl.℥i
Aquæ	ad 100		ad fl.℥iv

M. et Sig.: A teaspoonful, in water, three times a day, after meals.

℞	c.c.		
Tincturæ ferri chloridi	5		fl.ʒiss
Acidi phosphorici diluti	10		
Glycerini	10	or	āā fl.ʒiij
Aquæ	ad 100		ad fl.℥iv

M. et Sig.: A teaspoonful, in water, three times a day, after meals.

Or

℞	c.c.		
Tincturæ ferri chloridi	5	or	fl.ʒiss
Elixiris *aromatici*	ad 100		ad fl.℥iv

M. et Sig.: A teaspoonful, in water, three times a day, after meals.

As has been repeatedly urged, there is absolutely no necessity for the administration of any other form of iron, than those above mentioned. No organic iron can possibly do the physiologic or therapeutic work of the above irons, or do it any more pleasantly. If one adds to the above list the syrup of the iodid of iron, no other iron preparation is needed in the Pharmacopeia, and it is probable that a small dose of sodium iodid, administered at the same time or during the same day as one of the above iron preparations, would do better iron and iodid work than the iron iodid, certainly as good.

THYMOL, U. S. P.: THYMIC ACID

Description.—Thymol, genitive *thymolis,* is a phenol obtained from the oil of thyme (*Thymus vulgaris*). It occurs as large, colorless crystals, insoluble in water, but soluble in alcohol and in oils. Thymol is incompatible with a large number of drugs, such as acetanilid, antipyrin, camphor, chloral, menthol, and quinin.

Action.—It is slightly irritant to the skin, and very irritant, in concentrated solutions, to mucous membranes. If taken in the form of crystals, it is very slowly absorbed, unless fat or oil is taken with it or soon after it. It acts externally and in the alimentary tract as an antiseptic. It is much less soluble than phenol (carbolic acid) in the fluids of the stomach and intestine, and therefore much less readily absorbed; however, when much is absorbed, the symptoms are those of phenol poisoning. It is excreted by the urine in combination with glycuronic and sulphuric acids. Part of it is oxidized. During the excretion it may cause considerable kidney irritation, and if in large amount, even inflammation of the kidneys.

Action of a Therapeutic Dose, or the Primary Physiologic Action.—There should be no evident action from thymol, except locally the action of an antiseptic and internally the lessening of bowel fermentation and putrefaction, and the killing or stupefying of intestinal parasites. Any systemic effects are undesired, and are those of depression or beginning poisoning.

A *toxic* dose or toxic absorption gives symptoms of circulatory and muscular weakness, tremblings, cerebral irritation, renal irritation, and collapse. The treatment would be washing out of the stomach; a brisk saline purgative, as magnesium sulphate; circulatory stimulation; and other treatments indicated in phenol poisoning.

Therapy.—Thymol is too expensive to use as a general external antiseptic, and too sweet in order for use on wounds, ulcers, etc., as its odor is very attractive to flies, which is, of course, very undesirable. It is antiseptic in 0.1 per cent. solution, and has been used in this strength and much weaker for mouth washes and gargles; also in oily solutions as sprays for the nose and throat. Unless the solution is a weak one, it is irritant to the mucous membrane. It may be used as an antiseptic gargle in follicular tonsillitis and diphtheria, but peroxid of hydrogen solutions are much better. Thymol ointments in strength of from 5 to 10 per cent. have been used in various skin diseases, especially when there is itching. Lotions in weak solution have been used with advantage in various forms of pruritus.

As an intestinal antiseptic in diarrheas and in typhoid fever thymol has been generally used. It has no advantage, however, over salol (phenyl salicylate), and may cause more general disturbance. The principal use for thymol is as a specific in uncinariasis. It has also been used as an anthelmintic against the tape-worm and the round-worm.

Official Preparations.—Thymol enters into the composition of *Liquor antisepticus* (U. S. P.), and *Liquor antisepticus alkalinus* (N. F.), both used as gargles and mouth washes. Both preparations should be diluted for use. The dose of thymol itself is 0.10 gram (2 grains), best administered in capsules and never taken on an empty stomach unless a large amount of water or other liquid is taken at the same time.

Administration.—As already stated, the principal use for thymol is against the ankylostoma or uncinaria. It is here given in large doses on the morning following brisk catharsis. The best method is to order it in capsules, and then have the patient uncap the capsule at the moment of taking, and take it with a cup of tea or coffee, without milk, or a cup of plain hot water. It is unwise to give the patient milk or any other food at the time the thymol is administered, as it is desired that the intestinal parasites shall partake of the thymol, and food might interfere with the object desired. For action on this parasite the drug may be ordered as follows:

R	Gm.		
Thymolis	5	or	gr.lxxv

Fac capsulas 10.
Sig.: Take three capsules, with plenty of hot water or other hot liquid, at once, and repeat in one hour.

As stated, it is presumed that cathartic action has taken place either early in the morning or during the night, and the first dose of the anthelmintic should be at seven, and the next at eight o'clock. In from two to four hours magnesium sulphate should be administered, and one hour after this saline, the patient may receive food. This treatment should be repeated in a week.

SOLUTIONS FOR USE IN THE EARS

℞	Gm. or c.c.		
Cocainæ hydrochloridi	0|20		gr.iv
Sodii boratis	0|50		gr.x
Solutionis epinephrin (1-1000)	5	or	
Glycerini	5		āāfl.ʒiss
Aquæ camphoræ	ad 50		ad fl.℥ii

M. et Sig.: Ear drops. Warm before using.

℞	Gm. or c.c.		
Cocainæ hydrochloridi	0|15		gr.iii
Acidi borici	0|25	or	gr.v
Glycerini	10		fl.ʒiii
Aquæ	ad 25		ad fl.℥i

M. et Sig.: Ear drops. Warm before using.

R	Gm. or c.c.		
Acidi borici	2		gr.xxxv
Tincturæ opii	10	or	fl.ʒiii
Glycerini	20		fl.ʒvi
Aquæ	ad 50		ad fl.℥ii

M. et Sig.: Ear drops. Warm before using.

℞	Gm. or c.c.		
Epinephrini chloridi	0|03		gr.½
Glycerini	20	or	fl.ʒvi
Aquæ	ad 50		ad fl.℥ii

M. et Sig.: Ear drops. Warm before using.

EYE DROPS

℞	Gm. or c.c.		
Acidi borici	0|25		gr.v
Aquæ camphoræ	15	or	fl.ʒv
Aquæ	ad 25		ad fl.℥i

M. et Sig.: Eye drops.

℞	Gm. or c.c.		
Sodii boratis	5	or	ʒiss
Aquæ	100		fl.℥iv

M. et Sig.: Eye wash. Warm before using.

℞	Gm. or c.c.		
Zinci sulphatis	0|10	or	gr.ii
Aquæ	50		fl.℥ii

M. et Sig.: Eye drops.

FOR TOOTHACHE

℞	Gm. or c.c.		
Tincturæ opii	10		
Olei caryophylli	10	or	āāfl.ʒiiss

M. et Sig.: Rub on the gum, or apply with cotton to cavity.

Syphilis and Pauperism.—It is a matter of incalculable importance for society in general and for the community in particular to preserve the productive forces instead of losing them. Prevention, and prompt treatment of syphilis can save great sufferings and heavy expenses. It is much cheaper to treat syphilis promptly and thoroughly than to leave infected people uncared for, and thus wait until the affection becomes a permanent infirmity with the consequent disability. Preventive measures for diseases are indeed economical. These may be formulated in four paragraphs as follows: (1) Instruction and education increase the standard of morality and inculcate high respect for women. (2) Diminish the overcrowding in the tenement houses. In factories and establishments where girls and boys are employed, rules of strict respect for each other must be enforced. (3) Those who have been infected with syphilis must be treated. Hospitals should take care of venereal patients, and dispensaries should be within easy reach of everybody. (4) Prostitution should be under municipal surveillance, and infected prostitutes should not be allowed to remain at large, but should be confined in hospitals and kept under treatment until the manifestations of lues are no longer dangerous for transmission.—A. Ravogli, in *Interstate Medical Journal.*

SATURDAY, APRIL 15, 1911

ANCIENT EGYPTIANS AND MODERN MEDICINE

When, in 1907, it was decided to increase the height of the great dam at Assuan, the Egyptian government sought to lessen, as far as possible, the destruction of the monuments and relics of ancient life on the Nile, by securing for scientific study as much as possible of the most valuable material which would be submerged by the rise of the waters. Numerous cemeteries on both banks of the river were explored, and no less than 6,000 bodies, representing burials during a period of 5,000 years, became available for study. Dr. Elliot Smith, professor of anatomy in the medical school at Cairo, who had already done much work with similar material, was in charge of the anthropological investigations, and largely because of his understanding of pathology the results as reported contain much of medical interest.[1]

It seems that even six thousand years ago, in predynastic times, the population of the Nile valley was comparatively highly civilized, so that the history of civilization must go back much farther than the sixty centuries it can now be followed. During all that time man has been afflicted by at least some of the same diseases from which he now suffers, although perhaps not to the same degree. Professor Smith found no positive evidence of syphilis in the Nubians; tuberculosis was apparently uncommon, and the characteristic skeletal changes of rachitis were not observed. Rheumatoid arthritis seems to have been prevalent, especially in predynastic times. Urinary calculi were occasionally found, and one predynastic calculus analyzed by Shattock was found to be composed of a central body of urates and a shell of phosphates, indicating that six thousand years ago, as now, urate calculi caused cystitis and ammoniacal decomposition of the urine. The *Micrococcus ureæ* is probably quite as old as civilization. Fibrous adhesions around the appendix give the lie to jests about the "new-fangled fad of appendicitis." Gout left its traces in the form of "chalk stones" then as now; but caries of the teeth did not make its appearance until the early dynasties, first being found in the wealthier classes, and not becoming common to the masses until Christian times. Surely there was at this time no change from whole wheat to white flour—the cause to which our British colleagues are now ascribing the modern prevalence of dental troubles.

The chemists have also examined mummy material to some extent. Embalming as practiced by the Egyptians consisted simply in removing most of the viscera, pickling with salt, and letting the dry climate do the rest. Such preserved tissues, even after centuries, retain some of their original characteristics. When softened by soaking in weak alkali the different organs can be identified; the tubules of the kidney and the different layers of the skin are still recognizable (Ruffer).[2] A desiccated heart contained in a vase in the Louvre, and supposed to have been the circulatory center of Rameses II about thirty-one centuries ago, was found to show still the structure characteristic of cardiac muscle.[3] The fatty elements seem to resist chemical change especially well, and infiltrate the tissues in replacement of the decomposing elements.[4] The proteins remain in small part apparently unaltered and coagulable by heat, although they are largely decomposed into proteoses and other cleavage products. In the mummified tissues the usual amino-acids of proteins can be found.[5] It would seem that the biologic characteristics of the proteins are lost before the chemical, for most of the attempts to secure the precipitin reaction with mummy proteins have been unsuccessful. Only with the extremely delicate anaphylaxis reaction can the human origin of mummy tissues be established.[6]

INDIVIDUAL LIBERTY AND THE PUBLIC WELFARE

Legislation limiting women's labor to fifty-four hours a week is opposed by a representative of a manufacturers' association on grounds of pure chivalry—because this official is for woman, and believes in placing no restriction whatever on her activities. We are reluctant to align ourselves with those cynics who profess to feel suspicion when they see a representative of a manufacturers' association suddenly aroused to tender concern for the abstract rights of womanhood, or when they see the same association generously and disinterestedly engaged in vindicating those rights. Doubtless the members of the association are perfectly sincere in their belief that they know best what working women really want, and that they know better what is good for women than do the sociologists and physicians who have studied the question. We are even ready to credit these manufacturers with faith in the amusing arguments of their representative. The human mind is organized with a marvelous and almost unlimited capacity for belief.

The arguments in favor of "emancipating" woman by permitting her to work twelve, fourteen, sixteen or even eighteen hours a day if the fancy strikes her (and if she can find a kind-hearted employer willing to humor her little whim), seem good material for the cartoonists and paragraphers, but too flimsy to deserve refutation in a serious periodical; and, indeed, we should not mention them except that the underlying assumption is one which still has weight with many persons, and one on which the opponents of public health measures always rely. This assumption is that law is the only social agency which interferes with the freedom of the individual, and that a law prohibiting an individual from doing any act necessarily limits that individual's liberty. Compulsory vaccination, government supervision over foods and drugs, local option, the enforcement of quarantine, the compulsory reporting of contagious diseases—in fact, almost all measures for the public welfare—are bitterly decried in some quarters as infringements on the liberty of the individual. In the present instance, a few sorely misjudged philanthropists are determined that working women shall not be allowed to part with an unprofitable abstract right which the latter would like to exchange for more practical freedom.

It will be a gain for the world when the academic concept of absolute liberty departs at last to that limbo set apart for theoretical abstractions which have no relation to practical affairs. Absolute liberty is as impossible of achievement as a perfect vacuum, and as inconsistent with the conditions of life. We live in the midst of coercions, physical, social, economic and legal; and often a technical prohibition is actual release from oppressive compulsion. Effective freedom is built up as much of limitations as of opportunities. No one can draw breath and be entirely ignorant of this principle, yet so many disregard it that it is worth while for those who are working for reform in matters of public health and welfare to see to it that the public not only knows wherein its freedom consists, but realizes it.

THE EFFECT OF EXERCISE ON THE BLOOD-PRESSURE AND PULSE

A systematic investigation of the effects of various forms of exercise on the systolic, diastolic and pulse-pressures and on the pulse-rate has been carried out by Dr. O. S. Lowsley.[1] The observations were made on healthy men, mostly young athletes who were in training, and the results obtained were about what might have been expected. The blood-pressure and the pulse-rate were universally increased during exercise and were found to be above normal even at the end of periods of very exhausting work.

In this Lowsley's observations differ from those of certain other investigators, and he attributes this to the fact that he was able to take observations immediately after the cessation of exercise, before the subsequent subnormal phase had set in. After exercise there is a period of subnormal blood-pressure, and the more exhausting the exercise, the more marked and prolonged will this phase be. The rapidity with which the pulse-rate drops to normal is also determined by the degree of exhaustion. There is often observed, however, a secondary rise in rate during the period of subnormal blood-pressure. Very violent exercise of even a few seconds, as in the running of a hundred-yard dash, causes a much more pronounced and lasting negative phase than does more prolonged but moderate work. Gräupner has shown that mild rapid exercise causes a rise in blood-pressure in normal individuals which outlasts the period of acceleration of the pulse, while in individuals with weak hearts the blood-pressure falls before the pulse-rate has reached normal.

Lowsley suggests that the duration of the negative phase is a very fair index of the strain on the circulatory system and that the test might be used in determining the fitness of any individual for the performance of certain forms of exercise. He believes that if the negative phase lasts less than an hour it may be considered well within the "hygienic limit," but that if it lasts more than two hours it is a sign that the margin of safety has been exceeded. Physical directors have been obliged to depend largely on their general impression of the effects of races, games, etc., on their charges, except in the elimination of those who are obviously unfit, and such a measurable factor should be of considerable help to them in deciding the qualifications of those who are apparently sound.

SOCIOLOGY AND MEDICINE

The problems of sociology are, in most instances, problems of preventive medicine, and many of the problems of preventive medicine resolve themselves into sociologic questions. The cure of disease in its larger aspect lies in its prevention in the individual, the community, the state. Medicine in its practical application must inevitably become almost wholly a problem of prevention. This involves its operation on the mass rather than the individual, and, therefore, it becomes a sociologic problem, with the knowledge acquired through the study of pure science to aid in its solution. Waiting for disease to arise in the individual, and then attacking it, involves an enormous economic waste, a waste of time, energy, earnings, efficiency, of life itself, to say nothing of the suffering, which causes a waste of nerve force, or of the tax on those immediately surrounding the individual and charged with his care. Likewise, philanthropy, state or private, directed to the relief of individual suffering and disease due directly or indirectly to faulty sociologic or industrial conditions, even though at present commendable and necessary from the humanitarian standpoint, means a tremendous waste. The vast public appropriations for hospitals and sanatoriums for the care of individuals suffering from contagious and infectious diseases — tuberculosis for instance — when weighed against prevention really constitute a waste. Prevention means the saving of most of this waste.

---

[1] Am. Jour. Phys., March 1, 1911.

As great strides are being made in the acquisition of ultimate scientific knowledge, so also real progress is being made on the side of preventive medicine involving sociologic questions. A mere enumeration of some of the enacted and proposed legislative measures along the lines of public health and welfare will illustrate the point. The national Food and Drugs Act, supplemented by state and municipal enactments concerning milk and other foods; quarantine laws, the reporting and supervision of epidemic and other contagious and infectious diseases; compulsory vaccination; the investigation and regulating of public water-supplies, sewage disposal, etc., and, coming more truly within the realm of the sociologic, child labor laws, and laws concerning minimum wage and minimum hours of labor for both men and women; employers' liability laws; laws compelling the employment of safety devices in industrial pursuits; laws against the use of injurious chemicals in the arts; the establishment of public playgrounds; laws regulating the building of tenements, factories, etc., providing for proper light and air space; school inspection and open-air schools; laws to secure better housing conditions, better hygienic conditions in prisons, etc., and for the regulation or prevention of the social vices—all of these are problems of preventive medicine. Many of these measures have been enacted into laws and carried into effect either nationally or locally, and most of these topics are at the present time the subject of active agitation in the newspapers, in the magazines, in medical and sociologic associations, in congress or in the legislatures.

Seemingly, a good deal has been accomplished along these lines, but really only a beginning has been made. The problems of prevention may never attain complete solution, just as medicine may never become an exact science; but in both we are surely progressing. The sociologic problems of preventive medicine which have attained partial solution so far have been solved by the strenuous fighting of the physicians—the scientists—aided by the sociologists, advanced thinkers, the so-called theorists or reformers, who have had to contend every inch of the way against the reactionaries who have failed to see their own real interests. More recently, however, the practical mind has been made to see the material advantage in measures that were formerly thought to be merely visionary; and so we find a more liberal and tractable attitude on the part of councils, legislatures and congresses, corporations and individuals along lines that make for the public health and welfare, such as improvement in factory and other industrial conditions, the prevention of injuries, first aid, sick benefits, workmen's compensation laws, shorter hours of labor, minimum wage questions, and better housing conditions; and, in addition, we have the tremendous public activity in general hygienic and health matters.

In many of these measures of prevention we are behind foreign countries, as in the protection of workmen from injury and from occupational diseases in industrial pursuits, and in employers' liability and workmen's compensation laws. But the importance and justice of these things are becoming recognized by the employers of labor here, who realize that they have no moral right to exploit their employees under unhygienic or dangerous conditions to life and limb, and throw on the community the burden of caring for incapacitated wage-earners or their dependents. The injustice of this policy has reached the point of national recognition, and the President in 1910 approved a resolution adopted by Congress, calling for an official investigation of this matter. Opposition to such beneficent measures will, of course, always exist, and reactionary measures will be attempted, as in the instance of the efforts to abolish the tuberculin test of cattle in Illinois and Wisconsin, and the recent opposition of the secretary of the Illinois Manufacturers' Association to the limitation of the hours of labor of women in all occupations in Illinois to fifty-four hours a week. But the tide of progress in these sociologic measures of preventive medicine cannot be permanently stemmed, and along with legislation for a national department of public health—another measure whose object is prevention—they will be adopted sooner or later. Progress in knowledge is never along direct lines, but always in zigzags, which nevertheless end farther forward than where they started.

Current Comment

NEW AND NONOFFICIAL REMEDIES IN THIS ISSUE

A little over six years ago the Council on Pharmacy and Chemistry was created. No medical organization or society has caused such a revolution as has this Council in the six years it has been in existence. The nature of this revolution is known to all readers of The Journal, and it is not necessary to enlarge on it. The work of the Council has been both critical and constructive. The constructive part has resulted in the publication of an annual known as New and Nonofficial Remedies, or, in brief, N.N.R. This annual contains a list of the preparations which have been accepted by the Council; in other words, the preparations which have complied with the ten rules adopted. Practically all these articles are proprietary preparations, and N.N.R. is the only book, so far as we know, to which a physician can go for accurate information, impartially presented, regarding such medicines. The manufacturers may be depended on to furnish the medical profession with plenty of statements of the optimistic kind, but the better class of medical men to-day are not so easily satisfied with such information as they were five or six years ago. In order that every reader of The Journal may have it on hand for convenient reference, N.N.R. for 1911 is sent as Part II of this issue. It is recommended that this book be examined critically, and especially is it urged that physicians read the rules, which are printed in the front of the book, bearing in mind that these rules represent the principles on which a preparation is accepted or rejected. Much thought was given to the preparation of these rules, and the Council believes that they represent just principles. If our readers agree with the Council, then they certainly ought to limit their prescribing to those proprietaries which have been accepted. The Council has decided favorably or unfavorably concerning practically all the proprietary medicines on the American market; hence it is safe to assume that those not included in N.N.R. have not been accepted because their manufacturers either could not or would not make them conform to the rules.

PENNSYLVANIA MILK INSPECTION

The state health officers of Pennsylvania are making the seventh inspection of the more than 40,000 premises producing milk for sale. This work in Pennsylvania is said to be done in a more comprehensive way than has been attempted in any other state. The inspection is not only extended to premises producing milk for wholesale or retail distribution, but is made on every farm producing milk for sale to creameries, butter-making establishments, cheese factories, condensories, etc., and even includes dairy farms where the product is worked up at home for sale in the markets. The health department's inspection is purely a sanitary one and deals with the cleanliness of the cow, of the stable, the cow-yard, the milk-house, with cleanliness on the part of the milker and the purity of the water used about the dairy farm and milk house. It is entirely different from that conducted by the state veterinarian, who concerns himself with the health of the herd, and that by the dairy and food commissioner, who limits himself to the use of preservatives and adulterants in the milk. These different forms of supervision of milk production and distribution should insure a vast improvement in the quality of the milk-supply and be reflected in the general health conditions in the state.

FACTORS IN RAILWAY ACCIDENTS

According to Accident Bulletin 37 of the Interstate Commerce Commission, the number of persons killed in train accidents during July, August and September, 1910, was 321, and the number of the injured was 3,892. "Accidents of other kinds" are said to have numbered 22,328—2,948 persons having been killed and 19,380 injured. This includes those accidents sustained by employees while at work, by passengers in getting on or off cars, by travelers at highway crossings, by persons doing business at stations, etc., by trespassers, and others; but excludes "industrial accidents" and accidents to employees resulting only in slight injury. These figures, which read like statistics from some seat of war, are, it should be remembered, for but one quarter of the year and for the single industry of transportation. Some accidents, as clearly appears from the bulletin, are due to the element of human fallibility, as, when an engineer fails to heed a signal, or an operator delivers an incorrect order. They indicate the need for installing, wherever possible, safety devices, in regard to which Europe is said to be far ahead of the United States. Another cause alleged by a practical railroad man[1] is a tendency among railroad employees to make haste by cutting red tape. A third cause is the deliberate, cynical disregard of human safety which foreign observers are prone to consider an American characteristic. This is a factor which is not evident in the accident bulletins; but that community is fortunate which has no witness to its presence. Chicago, for instance, has the notorious "death-strip," a section of double street-car tracks laid so close as barely to permit cars going in opposite directions to clear each other, thus sentencing to be crushed to death any unfortunate—young child, aged, infirm, uninformed or merely heedless person—who happens to be caught between two such cars. This particular strip was constructed with full knowledge of its possibilities, the street-railway companies offering the amazing extenuation that the public would "become educated" to the danger. This expectation, it may be added, has been justified; at least, those members of the public whose education has been finished on the "death-strip" would now fill a small cemetery. This is merely one example. There are others in other cities. When the people are awakened to the possibilities and the necessities of the whole situation there will be a change. The reputation of this country for carelessness with regard to human life is not an enviable one.

COMMERCIAL UNTRUTHFULNESS—A PASSING EVIL

Among Europeans it has long been held that exaggeration, hyperbole, even humbug, is a characteristic that finds its highest development in the United States. We have been told this so often that, as a nation, we have almost come to believe it ourselves. Particularly, it is alleged, has this trait been prominent in the commercial world. It is true that in the past the protection accorded the American consumer has been largely a matter of academic interest rather than of practical legislation. Even to-day the man in the street purchases as "all wool" clothes made of a mixture of shoddy and cotton. In matters more closely connected with his life and health, however, the American citizen receives a greater degree of protection than is accorded the citizen of any European state. The passage of the federal Food and Drugs Act and its enforcement by honest and efficient officials have done much to safeguard the American people from those who would jeopardize the health of the nation for their own financial advantage. In a field peculiarly its own, the American Medical Association through THE JOURNAL and the Council on Pharmacy and Chemistry, has undertaken a task such as has been attempted in no other country—that of giving reliable information regarding medicinal products of a proprietary nature used by the medical profession. Untruthfulness and even exaggeration regarding the virtues of products put out for the use of physicians in treating the sick, is a lesser evil in the United States than it is in any

---

[1] Fagan, J. O.: Confessions of a Railroad Signalman, Houghton, Mifflin & Co., Boston, 1908.

European country. Yet less than a decade ago there was probably more fraud in the exploitation of proprietary medicines in the United States than existed anywhere else in the world. Thanks to a vigorous campaign carried on both by enlightened laymen and by the organized medical profession, the public consciousness has been awakened and the United States, instead of standing lowest in the scale of commercial probity regarding the sale of medicinal products, now stands at the head. That this fact is recognized by intelligent Europeans is evident from an editorial by Professor W. Heubner of Göttingen, a translation of which appears on another page.[1] We believe that, so far as pharmaceutical products are concerned, the American public is better protected, and the American medical profession more reliably informed, than is the public or the medical profession of any other country in the world.

ANIMAL EXPERIMENTATION BY CLERGYMAN SCIENTIST

According to a recent number of the Pittsburg *Christian Advocate*, the Rev. Maitland Alexander, pastor of the First Presbyterian Church of Pittsburg, is carrying on a series of experiments on monkeys in the hope of finding a serum for infantile paralysis. It seems that the Rev. Mr. Alexander has worldly possessions which enable him to interest himself in any avocation and that he has taken up scientific work, in addition to his professional duties, in the hope of helping to check the awful ravages of infantile diseases. The *Advocate* thinks it strange that some sentimentalists have not tried to create a public sentiment against Dr. Alexander and his associates for their use of monkeys. That this has not been done is truly surprising; doubtless the fact has not yet been brought to the attention of *Life*.

POSOLOGY

The determination of the proper dose of medicine is often a difficult problem; and the following from Manquat's "Principles of Therapeutics" is worth quoting:

> We should like to note that it is not good practice to seek to secure complete functional correction by means of drugs. If, through hygiene, the organism is placed under the conditions of optimum of function, a small dose often suffices to bring about restoration of the disturbed function. It is often better to be content with improvement and modestly live according to appropriate hygiene rather than to seek the medicamental triumph of complete functional restoration which will not last. A patient with mitral stenosis, for instance, who knows enough not to ask of his heart more than it can give, will have the greatest chances of continuing long without the aid of medicinal assistance; and when one is at last obliged to resort to digitalis, minute doses, as has been shown by Dr. Huchard, are to be prescribed. To content oneself with producing diuresis, through theobromin, in a patient suffering from renal insufficiency would be a reprehensible practice; it is better, first, to restrain all the endogenous and exogenous intoxications, and prescribe only small doses of the diuretic remedy, which can be repeated whenever necessary. The patient's mode of life and alimentation should first of all be adjusted to his functional forces, while medicinal intervention should be regarded as a therapeutic adjunct. There is a case, however, in which a large dose is demanded from the beginning; that is, in the presence of an accident menacing life, when an active medicament alone can restore the adequate function of the failing organ. Such is in particular the case in cardiac asthenia capable of endangering life, or in an alarming dyspnea, or in sudden anuria, in which large functional doses are necessary. There should then be no hesitation in seeking energetic action, unless some positive contra-indication exists. The patient's salvation may depend on such action.

The principles stated are correct. The drug is to be regarded only as a staff to assist lightly over the difficult places, and not as a strong crutch to bear the whole burden. First throw away the pack and the other impedimenta; give entire freedom of action to all the natural forces; assist by the staff only as actually needed and the steep will be surmounted. But when there is danger of falling over the precipice, then the most vigorous assistance must be supplied on the instant. The practical application of Manquat's plan, selecting in each instance the proper drug in the proper dose, and for the proper length of time, is a matter of knowledge, experience and the nicest discrimination.

UNIFORMITY IN DEATH CERTIFICATES

The increasing attention paid to vital statistics by the present Director of the Census cannot fail to be gratifying to physicians. For the accurate collection and tabulation of mortality statistics, not only is it necessary that uniform laws be adopted and enforced in the different states; it is also essential that local registrars, and especially physicians, follow a uniform system of nomenclature in filling out death certificates and reports. The American Medical Association for several years has had a Committee on Nomenclature and Classification of Diseases, which is cooperating with others, with a view to securing greater uniformity in terminology. Representatives of the various civilized governments (the United States included) have prepared an international list of causes of death which has been adopted by over twenty of the leading nations. In order to place this list in convenient form for ready reference by physicians, the bureau of the census is distributing to physicians, in large quantities, a pocket reference list in which are tabulated 189 causes of death, with notations showing the proper form in which the causes of death should be reported. The pamphlet also contains a list of undesirable terms and the history of the extension of the registration area in the United States. It is convenient in form and should be in the hands of every practicing physician. Any physician who has not already received a copy from the census bureau can secure one by addressing a postal card to the Director of the Census, Washington, D. C. General cooperation in the use of a uniform nomenclature will greatly increase the value of our vital statistic figures and reports.

AN EARLY EXPONENT OF THE GERM THEORY

Long before Pasteur demonstrated the relation of germs to disease, and 163 years before the discovery of the tubercle bacillus by Koch, Benjamin Marten, M.D., of London, is said to have published a book in which he set forth in considerable detail a theory of disease that covers in a surprising way the present accepted germ theory. His book, dated 1720, is entitled "A New Theory of Consumptions, More Especially of a Phthisis or Consumption of the Lungs." A number of copies of this book are in existence, one in the British Museum, and the February issue of *Janus* contains a reproduction of the title-page, and an article by C. A. Singer, in which are quoted at length the exact words of Marten in which he elaborates his theory. Speaking of "consumptions" in general, he says: "The original and essential cause, then, . . . may possibly be some certain species of animalcula or wonderfully minute living creatures, that by their peculiar shape, or disagreeable parts, are inimicable to our nature." and they may gain access to our bodies by the air we breathe, the food we eat and the liquor we drink, or perhaps in other unknown ways, and "being there deposited in a proper nidus or nest and being produced into life, coming to perfection or increasing in bigness, may by their spontaneous motion and injurious parts . . . cause all the disorders that have been mentioned." viz., plague, venereal disease, measles, small-pox, the "common rheum" and leprosy. He then develops this theory so as to account for tuberculosis of the lungs, and states his belief that if he had had glasses strong enough he would have been able to see these minute organisms. He discusses the possibility of intra-uterine or hereditary transmission, remarks that it is reasonable to suppose that specific diseases are due to specific organisms, and considers epidemic diseases in the light of his theory. He calls attention to diseases that seem to be communicated by contact, and from the fact that scabies is transmitted in this manner and is due to a little animal that could be seen by the glass, thinks it reasonable to conclude that syphilis might be carried in much the same way, although the organism could not be seen. He did not believe that all diseases were due to such organisms, but that those named probably were. He advanced this idea only as a theory, and in it he foreshadows the theory of bacterial toxins, for in speaking of treatment he recognizes the difficulty of killing the germs in the body, saying that even that would not cure the disease, as "their pernicious effects could not be supposed to be thereby so immediately cured, any more than destroying a dog that had bit a man could be supposed to cure the wound he had made with his teeth." It is astonishing how well, under the state of scientific knowledge at that time, he had worked out even details of his theory and how closely he skirted the reality. He thinks it is reasonable and probable, and hopes it will "afford sufficient hints to some able hand to carry the theory much farther than I have done, and, it may be, bring it to absolute demonstration." It was over a hundred years before this was done by Pasteur and Koch.

THE REFORMED ALMANAC AS A HEALTH EVANGELIST

From time immemorial the almanac has been the special advertising prerogative of the "patent medicine" company. Who does not find among the earliest recollections of his childhood the almanac with its medley of calendar, astronomical events, weather predictions, old jokes, medical advertisements and patients' testimonials? At least one such almanac was to be found in every household and it was, perhaps, the most frequently consulted book in the family possessions. To it the children went to find on what day of the week Christmas, New Year's, the Fourth of July and the family birthdays occurred. Mother and the girls always went to it to find when Easter was to come that year. Father was careful to look for the phases of the moon before doing his spring planting and grandmother used it to verify her predictions as to whether next winter would be mild or severe. Its value as an advertising medium was recognized by innumerable nostrum firms, which for years issued almanacs by the million copies. One of our later-day state board of health secretaries[1] has realized that if an almanac is a good thing to advertise nostrums it is an equally good thing to advertise health. The January-February number of the *Virginia Health Bulletin* is issued in the form of an almanac. It has the calendar by months, the phases of the moon, the time when the sun and moon rise and set for each day, the important historical events and all the other time-honored earmarks of almanacs, but instead of the musty jokes and stereotyped testimonials of patients "pronounced incurable by the doctors," but cured by two bottles and a half of Indian Bitters, it has sanitary aphorisms such as "An open window is better than an open grave," "A dirty well is more dangerous than a dirty kitchen," "A good iron pump costs less than a case of typhoid," "Good water is one of the best insurance policies a family can carry," "Two dollars for a doctor is cheaper than a hundred dollars for a funeral," "If your milk man brings warm milk, make it hot for him," "Wire screens in the window keep crape from the door," "Typhoid germs are small in size, but they are more expensive to keep than blooded horses," "A light overcoat is better than a heavy cold," "Many a cough ends in a coffin," "It is better to sleep in the fresh air than in the fresh grave." A special subject is assigned to each month—small-pox to January, pneumonia to February, measles to March, infants' complaints to May, typhoid to July, colds and influenza to November, and consumption to December—with a page of common-sense advice, in plain, simple language, under each topic. The Virginia Department of Health deserves hearty congratulations for its success in reforming one of our oldest family institutions and converting it into an evangel of health.

Syphilis and Cardiovascular Disease.—Syphilis as a cause of cardiovascular disease does not receive the attention its importance merits. Endarteritis with its consequences even to the extent of complete obliteration of vessels, especially in the heart and brain, can be traced to this disease.—C. W. Chapman, in the *Practitioner.*

---

Medical News

COLORADO

Personal.—Dr. Frank R. Spencer, Boulder, has gone to Europe.——Dr. Edward Delehanty has been elected president of the staff of St. Joseph's Hospital, Denver, vice Dr. Samuel D. Hopkins, deceased.

Medical Department of City Library.—El Paso County Medical Society is planning to put its library of text-books and periodicals into the public library of Colorado Springs so that the public may have access to this literature.

Charges Graft.—Dr. Elizabeth Cassidy, chairman of the finance committee of the board of commissioners of Denver County, claims that there has been great extravagance or graft in the management of the affairs of the county institutions and is said to have withheld monthly payments until thorough investigation has been made.

GEORGIA

State Society Meeting.—The Medical Association of Georgia will hold its annual meeting in Rome, April 19-21, under the presidency of Dr. Edward C. Davis, Atlanta. The headquarters of the association will be at the Cherokee Hotel, and the business sessions will be held in the superior court room.

State Tuberculosis Camp Opened.—The State Tuberculosis Sanatorium, Alto, was formally opened, March 21. Seven patients immediately availed themselves of the opportunity for treatment. The capacity of the institution is at present seventy, but the buildings have been so constructed that 300 patients can be accommodated at comparatively no additional expense.

District Society Meetings.—At the annual meeting of the Seventh District Medical Society, held in Cartersville, March 9, the following officers were elected: president, Dr. William J. Shaw, Rome; vice-president, Dr. Alfred B. Greene, Cartersville, and secretary-treasurer, Dr. Tanner Lowry, Eucharlee. Cartersville was selected as the next place of meeting.——The Fourth District Medical Society held its annual meeting in Carrollton. Drs. Joseph N. McCormack, Bowling Green, Ky., and Edward C. Davis, Atlanta, president of the state association, delivered addresses, and the following officers were elected: president, Dr. Charles A. Dexter, Columbus; vice-president, Dr. H. J. Goodwin, Roopville, and secretary-treasurer, Dr. Homer Boatright, Carrollton. The next meeting of the society will be held in Greenville, September 19.

Personal.—Dr. S. Wicks Merritt, formerly of Baltimore, has been appointed superintendent of the new tuberculosis sanatorium built by Atlanta and Fulton Counties.——Drs. John F. Harris, William E. Wood, Harlan L. Erwin and Jesse G. McAfee have been appointed members of the board of health of Dalton.——Dr. R. P. Sorrells, Athens, has purchased a large interest in Pine Ridge Sanatorium for Tuberculosis and has been elected secretary-treasurer and business manager of the institution.——Dr. R. J. Horne has been elected a member of the faculty of the Medical College of Georgia, Augusta, and Dr. Noel M. Moore has been reelected a member of the governing board.——The governor has reappointed Dr. Francis M. Ridley, LaGrange, a member of the State Board of Medical Examiners, and Dr. Jarrett W. Palmer, Ailey, a member to succeed Dr. Isham H. Goss, Athens.

ILLINOIS

Personal.—Dr. Harry S. W. Spencer, Kankakee, is reported to be seriously ill with pneumonia.——Dr. George C. Lewis, Fairbury, has retired after thirty years of practice.

Donates a Purse to Missionary.—The Waukegan Physicians' Club has made a liberal contribution which has been given to Dr. Margaret S. Grant who leaves in the early summer for China where she intends to make an exhaustive study of the pneumonic plague.

Legislation.—Senate Bill No. 235 has passed the senate and is now in the house of representatives. There is, apparently, organized opposition against the bill in the house and this is directed toward Section 6-A, which aims to give the State Board of Health jurisdiction in the matter of revocation, over all licenses issued since 1877. Under existing conditions, a physician licensed before July 1, 1899, may deceive and defraud the public, may commit any crime. may even be sent to the penitentiary, and yet remain a licensed physician, as under the decision of the Supreme Court. the State Board of Health has no jurisdiction over licenses issued prior to July 1, 1899. Under these conditions the board is unable to protect the people from the impositions of frauds, quacks, charlatans and impostors, and is rendered impotent in what was intended to be one of its most important functions, namely: "To detect quacks and to prevent them and all ignorant pretenders from imposing on the sick and helpless." The bill does not in any manner increase the requirements now demanded of medical colleges, but is a step in the direction of a higher, better, more practical and more thorough medical education. The bill has been amended so as to provide that a medical college, whose students shall be licensed to practice temporarily in a hospital under the direction of the college, shall require as a prerequisite to graduation, a course of study extending over at least five calendar years.

Chicago

Personal.—Dr. Rosa Engelmann has returned after a year in Europe.——Dr. and Mrs. Arthur R. Reynolds have returned from California.——Dr. and Mrs. Archibald Church and son have returned from Ocean Springs.——Dr. Ernest A. Loewinger was assaulted by unknown persons, April 9, but was not seriously injured.——Dr. Winfield S. Hall has been elected as head of the local branch of the National Health League.

INDIANA

State Conference of Charities.—The twentieth annual state conference of charities and corrections will be held in Indianapolis, October 28-31. Prof. W. G. Weatherly will preside, and the principal addresses will be delivered by Jacob Riis, New York City; Prof. W. H. Bailey, of Cornell University, and Miss Jane Addams, of Hull House, Chicago.

State Red Cross Report.—The Indiana branch of the American Red Cross reports that in the biennium, ended March 24, seventeen cases of tuberculosis among the deserving poor had been treated, at an average expense of $15 a week. These patients were housed in cottages near Danville. Not a single death occurred and cure is expected in all the cases. The association has erected six cottages at South Bend and expects to erect four more in that place, four cottages at Terre Haute, two at Vincennes and six at Indianapolis.

To Benefit Hospital Service.—The late Alfred Burdsall has left his entire estate, amounting to $700,000, to public and charitable institutions of Indianapolis, subject to a life interest for his wife. One-half of the amount is, eventually, to be given to the city board of health for the improvement and benefit of the hospital service of Indianapolis and to provide homes for incurables. His library and $5,000 in cash are bequeathed to the Indiana Tuberculosis Hospital, Rockville, for the erection of a library building, and the remainder of the estate is to be devoted to local charities and the department of public parks of that city.

Health Week at Fort Wayne.—Health week at Fort Wayne was inaugurated March 27, and, during the week, afternoon and evening lectures and demonstrations were held. Samples of tuberculous meats were sent daily from Chicago for demonstration. Among the speakers of the week were Dr. William A. Evans, Health Commissioner of Chicago; G. W. Porter, of the Bureau of Animal Industry of the Department of Agriculture; Dr. W. F. King, Assistant Secretary of the Indiana State Board of Health; Dr. Mazyck P. Ravenel, of the University of Wisconsin; Dr. Alice Hamilton, of Hull House, Chicago; Miss Lenna Cooper, a dietitian of Battle Creek, and Mrs. Caroline Crane, the sanitary expert of Kalamazoo.

Personal.—Dr. James M. Dinnen, Fort Wayne, has been recommissioned as a member of the State Board of Medical Examination and Registration.——Dr. Paul E. Bowers, Indianapolis, has been appointed physician to the northern penitentiary, Michigan City, vice Dr. J. W. Milliken, who has been made deputy warden.——Dr. John H. Alexander and wife, Greensburg, were assaulted and severely beaten by a drunken man, April 2.——Dr. Henry Gers, Washington, state senator, is in a serious condition as the result of a recent cerebral hemorrhage.——In the suit of Dr. Charles F. Cluthe, Evansville, against the Big Four System, in which $35,000 damages were claimed on account of the passing of the railroad through his property, the jury has awarded the plaintiff $1,500.

Violations of Pure Food Law.—During the past two weeks, the following violations of the State Food and Drug Laws have been decided: Three druggists in Indianapolis have been arrested and fined for failing to state the amount of alcohol in paregoric; one druggist in Indianapolis, for selling an impure drug; an individual in Bicknell was fined $25.00 for spitting on the floor in a food institution; in Nappanee a fine was imposed for selling spirits of camphor below the United

States standard; in Hammond, there was a conviction for selling oleomargarine for butter; in Gary, one for selling dirty milk in a dirty container; in Waveland, one for selling apple cider containing benzoate of soda; in La Fontaine, one for selling blackberry cider containing benzoate of soda; and, in Bicknell, the proprietors of an insanitary restaurant and slaughterhouse were fined.

IOWA

County Tuberculosis Hospital.—The Polk County Board of Supervisors has decided to erect a tuberculosis hospital at a site selected on the county farm. The plans provide for the erection of a large tent to accommodate twenty patients, and a permanent building to be used as a kitchen and dining hall for the inmates. During the summer the construction of a permanent hospital will begin. It is stated that residents of Polk County suffering from tuberculosis will be entitled to treatment without charge at the institution.

General Hospitals for Counties.—Two years ago the Iowa legislature passed a bill permitting counties to vote for the levying of a tax to build general hospitals and providing, also, for the erection of separate buildings for the care of tuberculous patients. At the November election eight counties voted on this question, but in only one—Washington County—was the vote successful. A tax of $25,000 was voted and the management was placed in the hands of a board of seven trustees, none of whom is a practitioner. A citizen of Washington donated a site containing 11 acres for the institution, and churches, lodges and private citizens have provided the furnishings.——At a special election, called March 22, Jefferson County voted to establish a general county hospital and voted $27,000 for this purpose. The Washington County hospital is expected to be ready before next winter. The credit for this good work should be given, largely, to the medical men in each county for their united action in the matter.

KANSAS

Personal.—Dr. Benjamin P. Smith, Miltonvale, has succeeded Dr. Chilton W. McLaughlin, Kansas City, as national medical director of the Sons and Daughters of Justice.——Dr. Josaphyne R. E. Davis, Ottawa, who has been under treatment in Kansas City, has returned and resumed her practice.

New Hospital for Kansas City.—The campaign to raise $200,000 for the new Bethany Hospital to be built on Mount Olivet, Kansas City, was started April 2. The territory included in this campaign consists of all of Kansas and all of Missouri south of the Missouri River, comprising the St. Louis conference district of the Methodist Episcopal Church.

Golden Belt Physicians Meet.—At the annual meeting of the Golden Belt Medical Society, held in Salina, April 6, Dr. Leonard S. Steadman, Junction City, was elected president, Dr. R. C. Brown, Kansas City, vice-president; Dr. L. O. Nordstrom, Salina, secretary, and Dr. John W. Neptune, Salina, treasurer. Dr. John G. Sheldon, Kansas City, Mo., conducted a surgical clinic for the society at St. Barnabas Hospital.

LOUISIANA

Personal.—Drs. Ralph O. Hollister, Augustus F. Gates and John L. Robinson have been appointed members of the Board of Health of Hammond.——Dr. Sidney D. Porter, Moreauville, medical inspector of the State Board of Health, has moved to New Orleans.——Dr. Sara Tew Mayo, New Orleans, has been awarded the *New Orleans Picayune* loving-cup which is donated every year to the citizen who shall be declared to have rendered the most signal and unselfish service to the people and best interests of the city.——Dr. Samuel A. Dickson, Shreveport, who has been critically ill is reported to be improved.——Dr. Charles A Schilling has been elected president, and Drs. Marion A. Young and Hartwell A. Eldredge have been made members of the Abbeville Board of Health.——Dr. William L. Grace has been elected president of the Plaquemine Board of Health.——Drs. Robert P. Jones and Tacitus W. Young have been appointed members of the Board of Health of Clinton.

MARYLAND

Baltimore

Operation on Dr. Barker.—Dr. Lewellys F. Barker was operated on for gall-stone disease by Dr. John M. T. Finney, April 10. The appendix was also removed. According to latest reports Dr. Barker is doing well.

Improvement in Marine Hospital.—Extensive improvements are being made in the United States Marine-Hospital. A new system of tuberculosis tents has been installed; a new electric lighting system has been put in operation; interior telephones have been placed and other minor improvements have been made.

Hospitals Benefit.—The Church Home and Infirmary is to receive, under the will of the late Miss Harwood, two-fifths of the estate which is appraised at more than $130,000.——The thirty day "Whirlwind Campaign" to raise $300,000 for additions to Mercy Hospital begins April 10. Cardinal Gibbons is at the head of the advisory board.

Portraits to be Presented.—At the coming meeting of the Medical and Chirurgical Faculty of Maryland, portraits will be presented of the late Dr. Francis Donaldson by Dr. William H. Welch and of Dr. Charles M. Ellis, Elkton, by Dr. Lewellys F. Barker. The annual oration is to be delivered by Dr. George W. Crile, Cleveland, O., and will be followed by a smoker. The scientific session of April 27 will be a joint meeting with the Maryland Pharmaceutical Association and will be addressed by Professor Charles Caspari, Jr., Pure Food Commissioner, and Mr. John B. Thomas of Baltimore.

MASSACHUSETTS

Prominent Dentist Dies.—Edward Walter Branigan, professor of clinical dentistry at the Tufts Medical School and for the past few months its acting dean, a trustee of the Forsyth Dental Infirmary, a member and former president of the National Association of Dental Faculties and a dental member of the American Medical Association, died in Charlesgate Hospital, Cambridge, March 23, from heart disease, aged 35.

New Talitha Cumi home.—The New England Moral Reform Society, which maintains the Talitha Cumi Maternity Home, is marking its seventy-fifth anniversary by the erection of buildings for the home on Forest Hills Avenue, Boston. A tract of 3 acres of land has been secured and the first group of buildings, consisting of the waiting department, the maternity hospital and the foundations and basement of the industrial home, will be erected at a cost of about $62,000. In the waiting department about forty can be accommodated at one time and the hospital can provide for thirty patients.

Personal.—Dr. Louis E. Dionne has been elected chairman and Dr. Albert G. Blodgett secretary of the Board of Health of Ware, and Dr. Harry D. Gafney has been appointed town physician.——Dr. William H. Keleher, Woburn, has been appointed medical examiner of the district comprising Woburn, Winchester, Lexington and Burlington, vice Dr. Harrison G. Blake, Woburn.——Major Frank P. Williams, M.C., N. G., Mass., has been detailed to attend the maneuvers on the Mexican frontier.——Dr. Theobald Smith, professor of comparative pathology in Harvard University, has been appointed visiting professor at the University of Berlin for the second half of the academic year 1911-1912.

Success of the Worcester Movement.—The undertaking inaugurated in Worcester County twenty-eight months ago to attack tuberculosis in wage-earners by an agreement among merchants and manufacturers to provide curative treatment, has resulted in the restoration of the wage-earning ability of more than 200 working people, most of them factory girls. There are at present more than 400 other individuals similarly afflicted, who are undergoing treatment at the expense of their employers, with satisfactory prospect of cure. The movement has now extended throughout New England, has gone as far west as Ohio, and experiments are being made in Japan, Bulgaria, Great Britain, France and elsewhere.

MISSOURI

Sanitarium Burns.—The Moberly Sanitarium was entirely destroyed by fire, March 27, with a loss of $60,000.

Hospital Notes.—The Jane Chinn Hospital, Webb City, was formally opened April 2. This building has been given to Webb City by Mr. and Mrs. C. R. Chinn, at a cost of more than $40,000. The institution will accommodate twenty-three ward patients and ten private patients, and is thoroughly equipped.——The Christian Hospital Association, Kansas City, has completed the pledge of $150,000 made obligatory by the provisions of the gift of R. A. Long who agreed to donate $200,000 for the building and site, provided that $150,000 should be raised as an endowment for a non-sectarian hospital.——An appropriation of $50,000 has been made by Kansas City for the pavilion for tuberculosis patients at Leeds Farm, on which work will be started this spring.

St. Louis

Hospitals Consolidated.—The merger of the Christian Hospital and Centenary Hospital was completed April 1. The new institution will be known as the Christian Centenary Hospital and will be located in the premises at present occupied by the Centenary Hospital. The new institution will be able to accommodate about one hundred patients.

Summer School of Medicine.—The St. Louis University School of Medicine announces that it will establish a summer course of medical instruction, beginning May 30 and continuing until July 8. The course of study will cover both clinical and fundamental branches and is intended to provide facilities for medical graduates who wish to take additional clinical instruction or to review fundamental subjects, and for undergraduates who desire to complete laboratory subjects in advance.

NEBRASKA

Medical Society Meetings.—The Gage County Medical Society, at its annual meeting in Beatrice, April 6, elected Dr. Harry M. Hepperlen, president; Dr. Aleck V. Robinson, vice-president, and Dr. Louis E. Penner, secretary-treasurer, all of Beatrice.——The annual meeting of Burt County Medical Association was held at Tekamah, April 5. The following officers were elected: president, Dr. Cook Craig; vice-president, Dr. S. A. Swenson, Oakland; secretary-treasurer and alternate delegate, Dr. Merrit Wood, Tekamah; censor, Dr. Edgar A. Sears, Decatur, and delegate to the state society, Dr. Andrew D. Nesbit, Tekamah.——Butler County Medical Society, at its annual meeting, held in David City, April 5, adopted resolutions condemning contract practice, and elected the following officers: president, Dr. Thomas J. Vanderhoof, Rising City; vice-president and delegate to the state society, Dr. Edgar D. Banghart, David City; secretary-treasurer and alternate delegate, Dr. Harry E. Marselus, Octavia; censor, Dr. Riley G. Rich, David City.

NEW JERSEY

Fire in Insane Hospital.—Fire set by a patient in the New Jersey State Hospital, Morris Plains, March 21, caused a great deal of excitement, but prompt action by physicians, nurses and attendants prevented any serious damage.

Milk Bill a Law.—Following the public hearing, March 17, on the Meyer milk standard bill, Governor Wilson has approved it, thus making it a law. The bill reduces the quantities of solids required in milk from 12 to 11½ per cent.

Typhoid in State Prison.—Three cases of typhoid fever have been reported in the New Jersey state prison. The health and water department of Trenton will install a chlorid of lime plant to aid in the purification of the city's drinking water until the proposed filtration plant can be completed.

Personal.—Dr. Charles H. Mayhew, Millville, is reported to be seriously ill with diabetes.——Dr. James K. Pollock, Trenton, has been appointed physician of the Southeastern Hospital for Insane, Madison, Ind.——Dr. Thomas E. Dolan has been reelected president, Dr. Joseph Funk elected vice-president and Dr. Theodore F. Livengood, secretary of the staff of Alexian Brothers' Hospital, Elizabeth.

County Society Meeting.—At the annual meeting and banquet of the Morris County Medical Society, held in Dover, the following officers were elected: president, Dr. Theodore W. Bebout, Stirling; vice-president, Dr. Gustav A. Becker, Morristown; secretary, Dr. Henry W. Kice, Wharton; treasurer, Dr. James Douglas, Morristown; permanent delegate, Dr. Abram E. Carpenter, Boonton, and annual delegates to the state medical society, Drs. Clifford Mills, Morristown, and E. Moore Fisher, Morris Plains.

The Widener Home.—P. A. B. Widener of Philadelphia will erect at Longport, near Atlantic City, a summer branch of the Home for Crippled Children, which he maintains in Philadelphia. Last summer he erected several cottages and the children were sent to the shore in groups. The new building will accommodate as many as are cared for in the Philadel-

NEW YORK

New York City

on for Thoracic Surgery Opened.—The trustees Hospital and Dr. Willy Meyer have announced of a pavilion for thoracic surgery. This ned for inspection April 8.

Babies' Hospital Ready.—The new babies' hospital of the Brooklyn Children's Aid Society is ready for use when the organization opens its Seaside Home at Coney Island for the season on June 20. There are accommodations for 100 patients and all kinds of cases will be taken.

Medical Society Can Try Physician.—The injunction obtained by Dr. Louis A. Ewald, to restrain the county society from trying him on charges of having changed the records of Sydenham Hospital so that it appeared that he had performed more operations than he really had done has been dismissed by the Appellate Division of the Supreme Court, which held that the society had the right to try the physician on the charges.

Control of Venereal Disease.—At a recent meeting of the Board of Health a resolution was adopted which expressed the sense of the Board of Health that the early adoption of a comprehensive plan for the sanitary control of venereal diseases is necessary for the protection of public health and called on the medical advisory board to submit recommendations. The resolution has committed the Board of Health to a definite request that the city erect a public hospital for such diseases.

Lectures for Physicians.—The following lectures will be given in the auditorium of the Educational Alliance on East Broadway: April 9, Dr. Albert A. Berg on "Lodge and Contract Practice"; April 17, Dr. William K. Polk on "Medical Ethics and Their Application to Practice"; April 23, Dr. Joseph Brettauer on "The Secret Division of Fees," and April 27, Dr. Sigismund S. Goldwater on "Abuses of Hospital and Dispensary Practice." These lectures are for physicians only and will begin at 8:30 p. m.

Memorial Meeting to Dr. Janeway.—The regular meeting of the Academy of Medicine on April 6 was devoted to addresses commemorative of the character and work of Dr. Edward G. Janeway. Dr. Francis Delafield spoke of him as the "Physician"; Dr. William H. Welch as the "Pathologist"; Dr. Abraham Jacobi as the "Consultant," and Dr. Joseph D. Bryant as the "Colleague and Friend." It was suggested by several of the speakers that a fitting memorial of Dr. Janeway be placed in the Academy of Medicine.

Buffalo

Increased Salaries in Health Department.—The salary of the health commissioner has been increased to $5,000, and a total of $12,000 a year in increases in salaries has been allowed in the department.

New Buildings for Hospital.—Concerted efforts are being made to raise a fund of $200,000 for the erection of new buildings for the German Deaconess Hospital, and of this amount $40,000 has been subscribed up to date.

City Hospital Site.—The question of a site for the new city hospital is still undecided. An 80-acre tract at West Farm has been offered the city for $225,000, and a tract of the same acreage at the driving park, for $325,000. These offers are still under advisement.

Personal.—Dr. Roswell Park has returned home.——Dr. George B. Stocker has been appointed deputy medical examiner for Erie County.——Dr. John D. Howland has been appointed medical superintendent of the Erie County Hospital.——Dr. Arthur C. Schaefer, assistant health officer, has been appointed a member of the medical staff of the Seventy-Fourth Infantry, N. G., N. Y.

NORTH CAROLINA

Medical Society Moves.—The Buncombe County Society has moved its library and office furniture to the rooms of the Asheville City Health Department and has made arrangements to have the library and reading room kept open constantly.

Personal.—Dr. Peter J. Gorman has been appointed superintendent of the State Hospital for Curable Consumptives, Aberdeen.——Major Eugene B. Glenn, M.C., N.C.N.G., Asheville, has been designated to attend the army maneuvers in Texas and has left for the frontier.——Dr. Hubert A. Royster, Raleigh, has closed a successful campaign for securing $75,000 for the erection of a new Y. M. C. A. building in that city.——Dr. Jacob H. Shuford has begun the erection of a hospital at Hickory.

PENNSYLVANIA

New Members of Board.—Governor Tener sent to the senate, April 3 the following nominations: Drs. Winters D. Hannaker, Meadville, and George A. Knowles of Philadelphia, to be members of the Board of Medical Examiners, representing the Medical Society of Pennsylvania.

County Bulletins.—The twentieth in the series of county papers issued in Pennsylvania is *The Bulletin of the Lancaster City and County Medical Society*. The *Bulletin of the Allegheny County Medical Society* is not only to change from a monthly to a weekly, but is to reach members of medical societies in adjoining counties as well as its own.

Philadelphia

Corinna Borden Keen Research Fellowship.—Graduates of the Jefferson Medical College who may wish to compete in this contest, for which a fund of $1,000 is available, should apply to the dean, Dr. James W. Holland, Walnut and Tenth Streets, Philadelphia.

Fire at Blockley.—The laundry at the Philadelphia General Hospital which was badly damaged by fire on April 6, is already being rebuilt. The damage to the structure is estimated at nearly $200,000. The short-circuiting of an electric mangle is believed to have started the fire.

Quarantined.—The Italian liner *Verona*, with 797 passengers was detained at Lewes, for examination for small-pox. Four men broke quarantine and the Philadelphia police were asked to assist in capturing them. Two were caught and examined by Dr. Andrew A. Cairns, of the board of health, and found to have been vaccinated.

Gift to Hospital.—C. Hartman Kuhn has conveyed the property, 1713 Summer Street, which he recently purchased for $14,250, to the Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases at Seventeenth and Summers Streets, as a memorial to his father, Hartman Kuhn. It is to be known as the Hartman Kuhn Memorial Building.

Former Foreign University Students' Meeting.—The Spring "Kommers" of the Philadelphia Branch of the Union of Former German University Students now residing in America will be held April 19 at the Hotel Walton. The guests of honor will be the members of the American Gastroenterological Association.

Personal.—Frederick W. Heyl, a druggist, has been appointed special examiner of drugs, medicines and chemicals.——Dr. Alfred Stengel, professor of clinical medicine in the University of Pennsylvania, was made professor of medicine of that institution April 4.——Dr. Henry K. Pancoast, formerly lecturer on skiagraphy at the University of Pennsylvania, has been appointed professor of roentgenology.——Dr. T. Turner Thomas, an associate in surgery, was appointed associate professor of applied anatomy.——Dr. Morris Longstreth will leave next month for a summer in Europe and on his return will make Boston his home.

Tuberculosis Conference.—The first Pennsylvania Conference of Tuberculosis Workers was held April 7 and 8. Dr. Charles J. Hatfield, Philadelphia, president of the Pennsylvania Society for the Prevention and Study of Tuberculosis, presided. The first session considered "A Program for an Antituberculosis Society which Employs no Paid Workers." The function of city, county and state in controlling tuberculosis was also a subject for general discussion and at the closing session, the "Opportunity and Need for Social Service in Antituberculosis Work" was discussed. The educational exhibit of the Pennsylvania society was presented for the visitors' inspection.

WASHINGTON

Protest Against Removal of State School.—At a meeting of the citizens of Medical Lake, a protest was made against the Bassett bill which provides for the removal of the State School for the Feeble-Minded to the west side.

Opposes Publicity.—The Spokane County Medical Society at its March meeting adopted a resolution requesting the lay papers not to publish notices of operations or personal items regarding physicians and their treatment of cases.

Nurses on Strike.—Refusal to grant an increase in wages to the nurses in the King County Hospital, Seattle, resulted in a strike of twelve nurses, which left the 250 patients in the hospital to be cared for by the superintendent and two nurses who declined to join in the strike.

Personal.—Dr. Alexander H. McLeish, Seattle, assistant superintendent at the Western Washington Hospital for the Insane, Fort Steilacoom, has been appointed superintendent of that institution and Dr. Albert C. Stewart, Tacoma, has been appointed the assistant.——Dr. Willis H. Corson, Seattle, has assumed charge of the King County Hospital.——Dr. William M. Newman has been appointed police surgeon of Spokane, vice Dr. John H. O'Shea

WISCONSIN

Counties Would Build Sanatoriums.—Winnebago, La Crosse, Marathon, Eau Claire and Kenosha counties are awaiting the action of the legislature relative to their right to erect sanatoriums for the care of patients with tuberculosis. La Crosse has already appropriated $5,000 for the erection of its sanatorium.

Personal.—Dr. Samuel G. Higgins, Milwaukee, assistant surgeon medical inspector, has resigned.——Dr. Albert J. Pullen has been elected president of North Fond du Lac.——Dr. Mazyck P. Ravenel, Madison, has been appointed by the United States Live Stock Sanitary Commission a member of the committee to investigate hog diseases, and especially hog cholera.——Dr. Frank A. Everhard has been appointed postmaster of Ripon.——Dr. and Mrs. Harry McElwee, Madison, have started for Europe.

GENERAL NEWS

Association on Medical Museums.—The fourth stated meeting of the International Association on Medical Museums was held *in the Auditorium, Chicago*, April 13, under the presidency of Dr. Alfred S. Warthin, Ann Arbor, Mich. The first part of the meeting was devoted to papers, and the second to a symposium discussion of the Experience Bulletin on the preservation of museum specimens in their natural colors, and this was succeeded by demonstrations of specimens and apparatus.

National Tuberculosis Meeting at Denver.—The annual meeting of the National Association for the Study and Prevention of Tuberculosis will be held in Denver June 20 and 21. Members of the American Medical Association may find it convenient to attend the meeting in Denver on their way to the Los Angeles meeting. Denver may be reached by the way of the regular trains previous to the national tuberculosis meeting, and then the special trains provided for the Los Angeles meeting may be joined at Denver or at some other point in Colorado.

Proctologic Program.—The American Proctologic Society will hold its thirteenth annual meeting at Los Angeles, June 26 and 27, with headquarters at the Hotel Alexandria. The preliminary program includes eighteen titles. The subject of the presidential address by Dr. George J. Cook, Indianapolis, will be "Proctologic Recommendations." A symposium is to be held on "Constipation," taking up its etiology, physiology, bacteriology and urinary findings, pathology and diagnosis, sequelæ, including autointoxication, psychotherapy, mechanical, electric treatment and massage, non-surgical and surgical treatment.

Health Report of Philippine Islands.—The eleventh report of the Bureau of Health of the Philippine Islands, presented by Dr. Victor G. Heiser, U. S. P. H. and M.-H. Service, Director of Health, contains the following recommendations for the improvement of the health service of the Philippine Islands: that the legislature enact a law for direct insular control of the Municipal Health Service; that a law for the commitment of the insane be passed; that the Manila charter be so amended that the cost of the abatement of nuisances existing on the property of private individuals, companies or corporations may be assessed against such property and become a prior lien on the same until paid; and that an extensive laboratory and research study of cholera be made with special reference to the influence of bacilli-carriers on the propagation of the disease, and also as to other means by which its perpetuation might be secured.

Annual Meeting of Territorial Association.—The eighth annual meeting of the Philippine Islands Medical Association was held in the amphitheatre of the College of Physicians and Surgeons, Manila, February 22 to 24, under the presidency of Dr. Benito Valdez y Salvadore, Manila. The election of officers was as follows: president, Dr. Robert E. L. Newberne, Manila; vice-presidents, Drs. Henry A. Shaw and Fernando Calderon y Roca, Manila; secretary-treasurer, Dr. Vernon L. Andrews, Manila; and councilors, Drs. Richard P. Strong and Benito Valdez y Salvadore, both of Manila. The presidential address was on "Electricity as a Powerful Therapeutic Agent." Dr. Fernando Calderon y Roca gave an interesting paper on "Infantile Beriberi," illustrated with lantern slides. Each morning before the beginning of the scientific program, a surgical clinic was held in the Philippine General Hospital by Drs. John R. McDill and Hans E. Schiffbauer.

Australasian Medical Congress.—The ninth session of the Australasian Medical Congress is to convene at Sydney, Australia, September 18 to 23, 1911. The meeting is organized under the patronage of the governors of the various states of

Australia, New Zealand and other prominent officials and scientists, and is to have twelve sections, with committees to report on hospital abuse, on contract practice and on syphilis. The secretary is Mr. Arthur Palmer, 121 Bathurst Street, Sydney, Australia.

LONDON LETTER

(From Our Regular Correspondent)

London, April 1, 1911.

Death From Being Blown Into the Air

At Bradford, a girl, aged 16, met death in an extraordinary manner. While in the playground of her school she was caught by a veritable tornado which carried her into the air. When she fell she sustained injuries so severe that she quickly succumbed. At the inquest evidence was given by the assistant school caretaker that the playground is in a very elevated position and that on several occasions he had seen girls blown off their feet but never actually into the air. In his thirteen years' experience he had never seen wind so violent as on the morning of the fatal accident. Another witness who was waiting for a car in front of the school said that he saw the girl in the air, her skirts blown out like a balloon. She was from 25 to 30 feet in the air, just above the school balcony (the latter, the coroner remarked, was 20 feet high). The caretaker said that he had often seen girls blown down in the school-yard and pinned against the wall, and frequently had to assist them into the school. The physician who was called found the girl unconscious and pulseless, suffering from severe concussion of the brain and compound fractures of the lower jaw, right arm, wrist and thigh. It appeared that she was wearing a pair of bloomers with an ordinary skirt but without petticoats. The jury returned a verdict of "died as the result of a fall caused by a sudden gust of wind."

The Decline of Tuberculosis in Scotland

Prof. Matthew Hay, health officer of Aberdeen, states that tuberculosis has been declining in that city for fifty years, although a decline did not begin to be felt in Scotland as a whole until after 1870. It began earlier in towns than in the rural districts. The decline began long before the germ origin of the disease had been demonstrated by Koch, although the infectious character of the disease had never been without believers. A remarkable fact is that the rate of decline was almost as great before sanitary precautions were taken against infection as since they were taken. It was plain, therefore, that the ameliorating agencies had been of a general and not of a specific character. No disease is so amenable to general hygienic conditions as tuberculosis. Eminent authorities have attributed the fall entirely to the increasing segregation of consumptives in institutions. But this applies only to the second half of the period of the decline. It seems extraordinary that the professor in coming so near the explanation of which he was in search as to describe it as a "general ameliorating agency," should have missed it. The period of fifty years to which he refers corresponds with the "free trade" epoch of this country, during which, in consequence of the removal of all taxes from food and all other commodities, an enormous increase has taken place in the prosperity of the people. Cheap food and higher wages were the causes.

Typhoid Traced to Fish Contaminated by Sewage

That typhoid fever may be due to sewage-contaminated shellfish, such as oysters and cockles, is now well-known, but that vertebrate fish may be similarly contaminated is a new theory. Sir Shirely Murphy, the health officer of London, has presented a report confirming the suspicion that has been entertained for ten years that plaice, which is largely supplied in the fried-fish shops, is a cause of typhoid fever. The investigation has been performed by Dr. Hamer, medical officer of the county council for special purposes, and is a remarkable piece of careful work. In the autumn of last year an outbreak of typhoid occurred in the East End of London; about 300 cases were reported from the thirty-third to the forty-second week. Only about 100 could be attributed to the causes ordinarily operative at this time of the year and, therefore, it was inferred that the remaining 200 must have been due to some special cause. The 200 cases showed a tendency to develop in clusters or groups, of which there were thirty-three. Water, milk and mussels were excluded as causes. When more than one case occurred in the same household the dates of onset were within a few days of each other, suggesting that the infection had been introduced into the house at the same time. Among seventy-nine cases occurring in Bethnal Green (a poor East End borough) sixty-eight patients gave a history of having eaten fried fish. Within the month of the onset, and of fifty cases in an area of special prevalence all the persons had eaten fried fish. Within the special area there were twenty-seven fried-fish shops, and of these it was found that three had been specially frequented by the persons attacked. All these shops obtained their supply from the great fish-market of Billingsgate. The fish was plaice and what is known as "late steamer fish," i. e., the cheaper fish which remains after the higher-priced fish has been disposed of. This fish is usually bought by fish friers. In the fish trade of London there is no systematic control by the sanitary authorities, such as is regarded as necessary in the case of other foods, though action has been taken as regards shellfish when they were shown to be a source of typhoid. Plaice appears to be the only fish used by the vendors of fried fish which is not gutted as a matter of course at sea. This is largely due to the fact that as the food of the plaice is largely shellfish it is possible to retain the gut without injuring the fish. In recent years, the practice of gutting plaice is coming into vogue; but, as a rule, no attempt is made to gut small plaice. These are commonly caught in vast numbers in shallow parts near the coast and they sometimes enter tidal waters. The suggestion is made that they become infected by sewage in the estuaries of large rivers.

Severe Epidemic of Measles in London

A severe epidemic of measles has prevailed in London for some weeks and is the cause of nearly 200 deaths weekly. Indeed the records of deaths which extend back for seventy years show that measles has never before caused so many deaths. As measles is not among the diseases which are required to be reported, systematic attempts to deal with it are not possible on the same scale as other infectious diseases, such as scarlet fever and typhoid. The unusual course has been taken of admitting measles patients to the fever hospitals, where there are now 803 cases, but these form only a small fraction of the cases in the metropolis.

Hospitals and Tuberculosis

Measures for the state control of tuberculosis continue to increase. The notification of cases of the disease to the health authorities is not yet universally compulsory but local authorities have the power to make regulations rendering notification compulsory in their districts. In 1908, the government issued regulations providing for the notification of pulmonary tuberculosis occurring among the inmates of poor law institutions, or among persons under the care of district medical officers. An order has now been issued embodying further regulations to provide for the notification of pulmonary tuberculosis occurring among the in-patients or out-patients at hospitals or similar institutions for the treatment of the sick which are supported, wholly or partially, otherwise than by the contributions of the patients.

Bill to Insure Greater Safety in Coal Mining

Recent colliery disasters, particularly the one at Whitehaven, in which, as the result of an explosion, over 300 men perished (previously reported in The Journal), have directed the attention of the government to measures for ensuring greater safety. Mr. Churchill, the Home Secretary, moved in the House of Commons the second reading of a coal mines bill which has been agreed to without a division. He called attention to the fact that a modern colliery with its elaborate plans for getting coal and bringing it to the surface, and for transmitting power for a long distance underground, and for forcing great volumes of air through passages many miles in length is one of the most remarkable examples of human activity. There are employed in the coal mines of the United Kingdom over 1,049,000 persons, of whom 846,000 are employed underground. This accounts for a substantial portion of the whole of the inhabitants of the British Isles. His bill deals with the health and safety of that large number of persons and is the result of a government commission appointed in 1906, and composed of both miners and mine owners, which made a prolonged and exhaustive inquiry into the whole condition of coal mining. The bill also comprises a number of amendments suggested by the government mining officials. It is divided into eight parts: management, safety, health, accidents, regulations, employment, inspection and supplemental. The death-rate from accidents in coal mines, which has been going down for over half a century, ceased to fall five or six years ago and last year there was a grave rise, 1,620 persons being killed in coal mines. The bill deals with all the main causes of accidents. First there are the dangers that arise in the shaft from improper raising and lowering of the cage, or breaking of ropes and chains. These the bill proposes to meet by providing that *no* winding rope shall be used for more than three and one-half years, and that no rope which has been spliced shall ever be used for raising or lowering persons. Overwinding, the cause of many accidents, is provided against by a greatly improved system of controllers and brakes. Another important provision forbids materials and tools being carried at the same time as men are wound up and down. Provisions are also made for ensuring that the shaft is kept in good repair. To prevent accidents from defective signaling there is a provision which secures a uniform system throughout the country. Coming to the ordinary risks to which the miner is exposed, 234 persons were killed last year by accidents connected with hauling or being nipped between the trucks and the walls, or by being run over. The bill requires that adequate space be provided between the walls and the trucks and sufficient refuges prepared. There are various complicated provisions making the hauling of coal less dangerous. The haulage road is too often the reserve alley which is the sewer of the mine by which obnoxious gases escape. The bill provides that there shall be another means of exit, and that in new mines there shall be two inlets, one for haulage and one for traveling. Proper apparatus for extinguishing fires and preventing accumulation of combustible material must be provided. To prevent the danger from falls of earth and coal, to which one-third of fatalties in mines are due, no man shall be allowed to work under an unsupported roof. To prevent the danger of gas explosion no man shall be allowed to work in any part of a mine where there is more than 2.5 per cent. of gas. There is also a provision for compulsory searching for matches. The use of electricity in mines is prohibited where it would be attended with risk.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, March 31, 1911.

The First Meeting of French Medical Journalists

This recent meeting was organized by the Association des journalistes médicaux français.

The first paper, by Dr. Ausset of Lille, was on the facilities which ought to be given to medical journalists in reporting congresses, etc. Resolutions were passed that summaries of the main addresses ought to be sent to all the journals eight days before the opening of each congress and that medical journalists should be given reduced rates on the railways.

Dr. Dieupart of Paris read a paper on the unauthorized assumption of the title of doctor by writers in the lay press, whose articles usually have an advertising purpose. A resolution was adopted warning editors against self-styled doctors. This resolution will certainly amuse the editors, who divide with such contributors the proceeds of their articles.

A paper was read by Dr. Vitoux of Paris on the unauthorized reproduction of medical articles. There are here medical journals which depend solely on reprinting articles without any authorization whatever, often even without credit. A resolution against the practice was passed.

It is too much to expect that this work will be of much use, since the Association des journalistes médicaux français is far from comprising the editors and publishers of all the most important publications.

Increase of Mortality from Diabetes

At one of the last sessions of the Académie des sciences, Dr. J. Le Goff of Paris called attention to the considerable increase of deaths from diabetes in Paris and in the department of the Seine. According to the *Annuaire statistique de la ville de Paris*, there were in 1880, 128 deaths caused by diabetes, or an average of 0.644 per 10,000 inhabitants; five years later, in 1885, the number of cases had doubled; in 1909 there were 525 or 1.93 per 10,000 inhabitants. Thus in thirteen years the number of deaths due to diabetes has quadrupled. The number of cases of diabetes in Paris has also increased considerably. It may be said, indeed, that formerly many cases of diabetes were not recognized. However, methods of analysis of sugar in urine have not varied for more than fifty years, and even before 1880 the pharmacists ascertained the presence and the amount of glucose by the Fehling method. This argument, therefore, has less value than has been attributed to it. If it be admitted that the number of cases has not varied for thirty years, it must be concluded that the mortality among the patients has quadrupled. Dr. Le Goff believes that the number of diabetics is increasing and the mortality among these patients is likewise increasing. To what should this considerable increase of a disease which was hardly known at the beginning of the last century be attributed? There are several causes. Persons who lead sedentary lives and take no physical exercise are most liable to become diabetics. Moreover, it is a question if the increasing consumption of sugar may not be regarded as one of the causes in the increase of diabetes. In fact, up to the seventeenth century, sugar was considered a medicament and was sold by pharmacists only. In the course of the eighteenth century, saccharose was obtained from the beet. The continental blockade gave a great impulse to the culture of this plant and during the whole of the nineteenth century, the consumption of sugar increased constantly. Thus in 1910, the amount consumed per person was 40.710 kg. in England; 31.4 kg. in America; 26.77 kg. in Switzerland; 19.11 kg. in Germany; 18.97 kg. in the Scandinavian countries; 17.68 kg. in Holland; 15.7 kg. in France, and 12.64 kg. in Belgium. It is in the countries in which the greatest amount of saccharose is consumed that the greatest number of diabetics is found.

Danger to Europe in the Defective Sanitary Condition of Russia

Dr. Lowenthal read a paper before the Académie de médecine on March 28, from which it appears that Russia is the only civilized country where cholera is endemic and epidemic. The epidemic of 1910 caused 130,000 deaths there. Preventable diseases affect one person out of four in Russia and a third of the patients die. In European Russia alone, there are more deaths from epidemic diseases than in the entire population of Europe, not including Turkey, which possesses no statistics. If the medical statistics on Russia and Japan are compared, the latter are seen to be much better, and this observation explains the difference of the sanitary condition of the two armies in the late war. The lamentable condition of Russia was due to the fundamental ignorance among the population, who did not understand the most elementary rules of cleanliness and hygiene. Moreover, while the rural population is entitled to free medical aid, the extent of the territory under the care of a single physician (on an average, 40,000 inhabitants scattered over 7,200 square kilometers or about 34,000 square miles), the distance of hospitals (sometimes by hundreds of kilometers), the absence of railroads, render this medical assistance precarious. Altogether, the sanitary condition of the Russian empire constitutes a permanent danger to Russia herself and a permanent menace for Europe and the entire world.

The Preparatory Schools of Medicine and Their Rôle in Medical Instruction

At the same session, Dr. Motais, professor at the Ecole preparatoire de médecine d'Angers, explained the advantage presented by the preparatory schools of medicine, of which there are twelve in France, at Amiens, Angers, Besançon, Caen, Clermont, Dijon, Grenoble, Limoges, Poitiers, Rheims, Rouen and Tours; there are altogether 641 pupils. Thus, there is no crowding in the ampitheaters of anatomy or the hospitals, consequently, these schools offer more favorable conditions for the first years of medical education than the more crowded scientific centers of the great cities. Professors Blanchard, Guyon, Gariel and Pouchet, of the Faculté de médecine de Paris, like Dr. Motais, believe in these provincial schools. Gariel and Pouchet declare that they have often given examinations in these schools and have observed the superiority of the candidates over the pupils of Paris. Dr. Bertrand, inspector general of the marine sanitary service, emphasized the services rendered by the schools of naval medicine, the suppression of which is demanded each year in parliament.

Reform in Medical Examinations

Up to the present the candidates at the various examinations of the Faculté de médecine were able, by consulting the announcements posted on the walls of the school, to learn at least fifteen days in advance the names of the members of the examining board. It will not be so hereafter, for the counsel of the school has decided that the names of examiners shall be hereafter kept secret. This reform has been undertaken to insure greater impartiality of examinations and to avoid abuse of the recommendations with which some candidates overwhelm the members of their jury, once known. Moreover, certain members of the examining boards, Professors Nicolas and Gariel, for example, who were known to be particularly severe, were avoided, many candidates failing to present themselves to undergo examination when they were to have these examiners. The students are much excited and have taken measures to obtain the reestablishment of the former state of things, but they will receive a categorical refusal.

Personal

At its session of March 28, the Académie de médecine elected a member in the section of pathologic anatomy to replace Professor Raymond, who died last September; Dr. Brault, physician of the Lariboisière Hospital, was chosen. Dr. Brault was one of the most active collaborators of the late Professor Cornil, and has published a number of works, especially on the pathologic anatomy of the kidneys, the liver and the arteries.

The Clinics of Industrial Accidents

In the last general assembly of the Syndicat médical de Paris, Dr. Pelisse read a report on certain so-called clinics of industrial accidents which do not confine themselves to receiving injured working men but employ very dubious expedients to invite such patronage. They are veritable shops with great show-windows decorated in extravagant colors to catch the eye of passersby, reinforced by striking radiographs, and sometimes harboring self-styled lawyers of more or less shady reputation who seek to extort from the insurance companies three or four times what they ought to pay. The most usual method of attracting patronage is to give each injured workman who comes to the clinic for the first time a certain sum of money. Another is to give a premium to everyone who brings there an injured workman.

After hearing Dr. Pelisse's report, the *syndicat* resolved that the attempt to attract victims of industrial accidents was reprehensible and unprofessional, and that every physician convicted of using such means should be excluded from professional societies.

Present Condition and Enlargement of the Beyrouth Medical School

In 1881 the French government and the superior of the Jesuit mission in Syria came to an understanding which resulted in the creation of the Faculté catholique et française de médecine et de pharmacie de Beyrouth. It was agreed that the Jesuits should have the direction and administration of the institution and that an annual allowance from the French government should guarantee the payment of the salaries of the professors and the maintenance of the laboratories and the library.

The diplomas are delivered and the control is assured by professors sent from France each year. The courses opened in 1883. The buildings, the teaching body and the equipment of the laboratories were planned for a maximum of sixty students, which no one anticipated would be exceeded in the future.

The school, however, has undergone considerable development. To-day, after twenty-seven years of existence, it has more than 250 students and, consequently, the buildings, equipment and faculty and, especially, the hospital facilities, are entirely inadequate. The administrators therefore have planned (1) to construct new buildings large enough to give 400 pupils the best and most modern medical instruction, and (2) to provide the hospital needed by the school with a sufficient number of beds for the general clinics of medicine and surgery and special services for children's diseases, cutaneous diseases, syphilis, diseases of the eye and an isolation pavilion for contagious diseases. The construction and installation of the new buildings will be undertaken by the school at its own expense; but it will be unable to do more. It therefore appeals for means to construct the hospital to the French government, which will probably respond favorably and will retain the control of the school.

Large Bequests to Scientific Institutions

In France, unlike the United States, scientific institutions are rarely aided by private gifts and bequests from rich men. A strong impression has, therefore, been created by the will of M. Loutreuil, a rich manufacturer who recently died leaving the greater part of his fortune to science. M. Loutreuil bequeathed $20,000 (100,000 francs) to the Institut Pasteur; $200,000 (1,000,000 francs) to the Caisse des recherches scientifiques; $500,000 (2,500.000 francs) to the Université de Paris. Moreover, desiring to contribute to the progress of the sciences taught or studied by scientists and independent investigators in other institutions of higher scientific culture, and being impressed by the meagerness of their resources in comparison with what they have in other countries, M Loutreuil bequeathed $700.000 (3.500.000 francs) to the Académie des sciences, to be distributed to the best advantage.

BERLIN LETTER

(*From Our Regular Correspondent*)

Berlin, March 24, 1911.

Personal

Professor Lucae, formerly for many years director of the ear clinic in Berlin, died March 17, at the age of 76. In view of the present demand from many sources in Germany for a combination of otology and laryngology, it is of historic interest that Lucae in his thesis for the doctorate took as his theme the "Technic and Importance of the Laryngoscope Introduced into Medical Practice in the Year 1858." He entered his special field at the suggestion of Virchow. After he had worked in Vienna, chiefly with Politzer, and in London with Toynbee, he continued his studies in Berlin and became connected with the faculty here in 1866. He soon founded a policlinic for ear diseases, and in 1881 an otologic clinic. Lucae made important contributions to all departments of otology, of which his treatises on the origin and foundation of the subjective sense of hearing and the importance of sound conduction by the bones of the head are worthy of special notice. In his work he was materially aided by his unusual musical talent. Some years before his death he retired from his official position, but still took an active part in the transactions of the Berlin Otologic Society.

Berlin otology has suffered another loss in the removal from the city of the well-known Professor Hartmann, who has retired to his native place, Heidenheim in Würtemburg. As an evidence of the esteem and popularity which Hartmann has enjoyed in Berlin, a banquet was given in his honor.

Professor Busse of Posen has recently accepted a call as successor of Professor Schmidt in the chair of pathologic anatomy at Zurich.

The Berlin Medical Society on the Vaccination Law

As I mentioned in a previous letter, a motion has lately been introduced and discussed in the Reichstag to the effect that a conscience clause with regard to vaccination should be introduced, similar to that in force in England, namely, that anyone who shall declare to the judge that vaccination is contrary to his conscientious belief, shall not be compelled to have his child vaccinated. Correctly estimating the danger which this clause would bring to the vaccination law, the Berlin medical society at its last session adopted a resolution proposed by the well-known pediatrist, Professor Baginsky, which reads: "In view of the latest discussion in the Reichstag, the Berlin Medical Society declares its conviction that it is absolutely necessary to maintain the German vaccination law of April, 1874, intact, and that especially the introduction of the English conscience clause would be attended with the gravest danger to the German people." It is remarkable that none of the antivaccination physicians, who have formed themselves into a special society, were present at this meeting. The resolution was adopted unanimously without debate. To this antivaccination medical society, as a matter of course, belong only members who have always opposed the so-calle "school medicine," and are partisans of the *Naturheilmetho* or Nature cures. Presumably, they hope to do better busin in this way.

Suicide in Prussia

Suicides increased in Prussia in 1909. There were 8,422 persons who took their own lives, as compared with 8,231 in 1908. Among these there were 6,466 men (in 1908, 6,371) and 1.956 (1,860) women. There were 21.6 suicides per 100.000, as compared with 21.4 in 1908, 20.2 in 1907 and 19.5 in 1906. The relative number of men was 33.6 (in the previous year 33.5), and of women 9.9 (9.6). The increase was much more marked among women than among men. There is a relative increase of suicide with advancing age. Among 100,000 persons from 10 to 15 years of age there were 1.7 (in 1908, 0.7) suicides; from 15 to 20, 16.9 (15.0); from 20 to 25, 27.3 (26.2); from 25 to 30, 20.7 (20.4); from 30 to 40, 24.2 (24.9); from 40 to 50, 37.4 (39.2); from 50 to 60, 59.9 (55.1); from 60 to 70, 56.3 (56.6); from 70 to 80, 55.8 (61.0); from 80 to 90, 54.1 (55.7). It may readily be seen from the figures that the number of youthful suicides has markedly increased since 1909. Indeed, while we find this increase in the period from 10 to 15 years in which with the small absolute number a few cases more or less may occasion a remarkable change in the relative figures, we find also that in the period of from 15 to 20 and from 20 to 25 years, where the numbers are larger, the relative figures are larger than they have been in any previous year. In accomplishing self-murder, hanging plays the principal rôle; 56.1 per cent. of men and 38.1 per cent. of women suicides hung themselves;

11.4 and 28.8 per cent., respectively, drowned themselves; 20.2 and 3.2 per cent. shot themselves, and 6.1 and 19.3 per cent. took poison. Poisoning and drowning, together with jumping from a height, are the modes of suicide more frequently selected by the female sex than by the male, while, on the other hand, six times as many men as women end their lives by shooting.

Thirty-Second Congress of Balneology at Berlin

RADIUM IN THERAPEUTICS

The importance of radium in therapeutics formed an especial subject of discussion at the thirty-second congress of balneology held in Berlin, March 2 to 6. The well-known physicist, Professor Marckwald, treated the subject from the physico-chemical standpoint. Of the three kinds of rays produced by radium, the alpha rays possess no power of penetration, the beta rays are cathode rays and have considerable penetrating power, while the gamma rays, which are similar to the Roentgen rays, have the greatest penetrating power. Radio-active elements are such as are in constant process of destruction. The most important forms of radium, especially with reference to balneology, are those which have the shortest life period. Dry radium salts give off no emanations, but they may become a source of emanations if one simply breathes on them. There are two radio-active families, those derived from uranium, and those from thorium. The former yield short-lived decomposition products or emanations, the latter long-lived; therefore, the uranium products are of greater therapeutic importance. Heretofore not enough attention has been given to the decomposition products in the measurements. The estimation of springs for their radio-active value should not be undertaken until after three or four hours. In conclusion, the speaker emphasized the necessity for a single and international standard of unit of measurement for radium. Kionka, professor of pharmacology in Jena, who has made a special study of radium, described its importance from a biologic and therapeutic standpoint. The tissues are markedly affected by radium, so that all forms of tissue irritation from simple reddening to necrosis can be produced on the skin.

RADIUM IN TREATMENT OF GOUT AND RHEUMATISM

The influence of radium on uric acid is therapeutically important, Kionka continued, as radium converts this substance from an almost insoluble into an easily soluble form. Further, under the influence of the emanations the purin metabolism is accelerated. These two properties of radium are of the greatest importance in the treatment of gout. The emanations seem to have no special affinity for blood, like that of oxygen for hemoglobin. The best form of introduction of radium is by inhalation, as the radium also leaves the body with the expired air. Drinking and bathing in radio-active water seem to be likewise effective, but far less than the inhalations. The strongest radio-active springs known to date are those at Landeck, Johannisthal and Gastein.

Dr. Fürstenberg, assistant at the university hydrotherapeutic institute, named as the chief indications for radium, gout and rheumatism. He has noted a hypnotic action of the emanation and a temporary slight increase in the body temperature. A Kreuznach physician, Dr. Eichholz, opposed the general view of the advantage of the inhalation method over the method of drinking. Dr. Ruhemann, a Berlin physician, has had radio-active biscuits made by incorporating a solution of 1.000 or 1,500 units of radio-active salts in zwieback, in which they could be demonstrated for three months. It was asserted by Dr. Plesch, an assistant of Professor Kraus, that the blood-pressure sinks in the emanatorium, during inhalation of the emanations, and that the emanation behaves in the blood as an indifferent gas. This gas is absorbed only to a very slight extent from the intestine, and does not reach the arterial blood, as it is immediately excreted by the lungs.

CARBONATED BATHS

Professor Goldscheider, the present director of the university policlinic for internal medicine, presented a communication on the action of carbonic-acid baths. He opposes the explanation of the action of carbonic-acid baths given by Senator and Frankenhäuser, as this theory does not take into consideration the action of carbonic acid on the nerve terminals, which has been discovered experimentally by him. Carbonic acid acts chemically as a gas on the endings of the thermal nerves and hinders the escape of heat from the skin. In the carbonic-acid bath the conditions are such that the water first affects the skin and withdraws heat from the body; then here and there bubbles of carbonic-acid gas take the place of the water, but do not remove so much heat from the skin. A certain contrast of temperature thus arises. But now the bubbles of carbonic-acid gas do not lie directly on the skin, but there remains between the skin and the carbon dioxid bubble a very thin layer of water, which is of very great importance for the whole question. If the Senator-Frankenhäuser theory was correct, an air bath would be similar in its action to a carbonic-acid bath. But this is not the case. The carbonic-acid baths have a peculiar action depending on the chemical properties of carbonic acid.

BRIEF HOT PLUNGE BATHS

Privat-Docent Dr. Determann, the well-known director of the sanatorium at St. Blasien, discussed hot plunge baths. Hot plunge baths at the temperature of 37 to 45 C. (98 to 113 F.) produce a marked stimulation of the functions of the organism, and most of all increase the capacity for muscular exertion. The physiologic action of hot baths of longer duration is thereby avoided. In the short hot plunge bath there occurs first a severe terrifying sense of pain, with a brief pallor of the skin, which is rapidly followed by hyperemia. The reaction in the hot bath follows without any active effort; patients have never taken cold after the hot plunge bath. These brief hot plunge baths are indicated in spinal neurasthenia, in certain forms of asthma in young people, and in conditions of peripheral irritation and pain, such as neuralgias, especially those on a hysterical basis.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, March 23, 1911.

Care of the Teeth of Schoolchildren

A movement has recently been initiated in this country, as in England and America, to have the teeth of schoolchildren cared for. A preliminary report by a committee authorized to make investigation showed that fully 80 per cent. of the large number of children examined had defective teeth. In our country we have compulsory elementary teaching; therefore all Austrian children between 6 and 14 years of age, except a very few, who are educated at home and have to pass their examinations in the public schools, may be found in the schools. These distressing data have suggested the formation in Vienna of a society for the care of the teeth of schoolchildren (Gesellschaft für Schulzahnpflege), whose aims are endorsed by the government and teachers as well as by the professors. Within a few weeks, many hundreds of members have been recruited, and the society has taken up its work. No treatment is given in the schools. The teeth of the children will be examined in each school periodically (every four or six months) and those found defective will be marked out. The parents will be informed of the result of the examination, and for those who are really poor, certain dentist surgeons have consented to perform the necessary dental operations free of charge. The teacher of each class will be authorized to see if the recommendations of the dental expert have been observed by the parents or the child. It is intended to have instructive lectures on the importance of healthy teeth, delivered twice a year in each class before the children, and also to award small prizes to those who, at the end of the term, have normal healthy conditions in the mouth.

Appointment of Professors to the Vacant Clinics

As has been mentioned in a previous letter, those two men who have been considered as being the most acceptable candidates, have been appointed ordinary professors in the Vienna medical faculty: Professor Ortner from Innsbruck who will succeed Strümpell as chief of the third medical clinic, and Professor Chvostek, who will be made head of a new, fourth, medical clinic. The latter clinic is a necessity, since the number of students and also patients has lately increased to such a degree that the old clinics have become absolutely inadequate. The fourth clinic will open at the beginning of the winter term in October. Another vacancy is to be filled, that after Escherich. The medical faculty of the Vienna University has nominated as its candidates, Professor von Pirquet (who is at present in Breslau and was for some time in the United States), Professor Pfaundler, and Docent Dr. Hamburger of Vienna, in the order mentioned. All these men are Escherich's pupils and there is no doubt that the first-named physician will be appointed, while probably the third will be called to take a prominent place in a German university town.

Combating the Smoke and Dust Nuisance

On account of the increased traffic in and growing industrialization of this city, the amount of dust and smoke has become an unwelcome feature in Vienna. Especially the dust is a bad nuisance here. We have a large proportion of windy days, hardly more than 27 days out of 365 without wind. The material with which the streets are paved is a kind of granite, which is quickly ground into fine sharp dust under the stress of street traffic. These two circumstances have been for a long time held responsible for the frequency of tuberculosis in Vienna, but all the efforts of physicians to procure a more healthful or scientific pavement have hitherto been fruitless. At last, a large and very influential association has been formed consisting of high officials of the state, of physicians, bankers and industrial men. This society has already succeeded in inducing the local municipal corporation to pave all new streets with a special non-dust-producing asphalt, while the old streets will be gradually converted also into asphalt streets. Furthermore, throwing dust out of the windows into the streets has been prohibited now by order of the police. The collection of household refuse, hitherto a fruitful source of most dangerous dust-clouds, has been made the object of a very thorough investigation, and several methods of dust-free collection are at present on trial. The society also fights the smoke nuisance. It has in this line two very encouraging results, for an amendment to the new building act of the city requires the installation of smoke-destroying apparatus in all new houses built after July 1, 1911, and the gradual installation of such in all factories within the precincts of Vienna up till 1913.

Miscellany

Vaccination Effective in the Philippines.—Another timely contribution to the value of vaccination is found in the report on small-pox and vaccination in the Philippine Islands by Dr. Victor G. Heiser, Director of Health in the Philippines, which was referred to editorially April 8, 1911, p. 1041. Dr. Heiser's report follows: During December a person afflicted with small-pox was transferred from San José, Antique, to the Island of Caluya, which is a small isolated island south of Mindoro, the inhabitants of which have heretofore not been systematically vaccinated. An old woman took some of the contents of a pustule from the small-pox case shortly before death and vaccinated a number of the inhabitants. Small-pox in epidemic form soon resulted. The population of Caluya and nearby islands is about 2.000. Approximately, 1,000 cases of small-pox occurred before the facts became known to the outer world. Vaccinators properly equipped were immediately sent to Caluya. They vaccinated 800 of the remaining 1,000 persons. Of these, not one contracted small-pox who had a successful vaccination that was 2 weeks old. Dr. Victor G. Heiser, Chief Quarantine Officer, visited ten families, with from five to eight members. In six of these, every member was stricken with small-pox. Physical examination showed that they had no vaccination marks. In two other families six persons were stricken and two escaped. Physical examination showed that of the six stricken members not one had been vaccinated. The two remaining members had successful vaccination marks. On inquiry, it was learned that they had visited Calapan a year previously and were vaccinated while there. In two other families that lived in the midst of a small-pox-stricken village, there were no cases of small-pox. Examination showed that they had good vaccination scars. Further inquiry elicited the statement that they had but recently come from another island where they had been vaccinated. In one house, one person was found with varioloid. On inquiry, it was learned that he had been vaccinated during childhood. Net result: Community of 2.000 population; 1,000 unvaccinated persons contract small-pox; 400 die; 800 are protected by vaccination; no cases occur after the incubation period was passed; no deaths occur. The remaining 200 are semicivilized and fled from the vaccinators, and their condition is unknown.

Morphologic Changes in a Mouse Carcinoma.—A systematic microscopic study was made by R. Kilduffe of the different generations of a carcinoma transplanted into white mice. The original tumor had developed spontaneously in a mouse. The sections studied covered a period of experimentation with the tumor extending from March, 1907, to June, 1910, and comprised all generations produced in that time. The sections were divided into four groups according to the history of the tumor. (a) Sections of the original tumor transplanted without experimental interference or modification, "the unheated series." (b) Sections of the tumor which had been heated to 44 C. for varying periods of time before inoculation through successive generations, "the long-heated series." (c) Sections of the tumor which had been heated before inoculation for varying periods of time as in (b), but through a shorter number of generations, "the short-heated series." (d) Sections of tumors, of which some generations had been heated for varying lengths of time, and other generations had not been heated, "the mixed series." The object of this investigation was to determine what changes in the morphologic character, if any, took place as a result of the various manipulations to which the tumor had been subjected before inoculation. This tumor was but slightly, if at all, affected morphologically by the experimental manipulations to which it was subjected, for no permanent morphologic change was produced through the influence of the physically injurious conditions to which it was exposed before inoculation. Kilduffe emphasizes the fact that the experimentally produced decrease in the energy of growth of these tumors did not change the alveolar character to an acinous one. A return to an adenomatous structure, described as a result of weakening tumor growth through transplantation into resistant animals, was not observed after a direct weakening of the growth through the influence of physical agencies.—*Journal of Experimental Medicine.*

Liver Necrosis of Chloroform Poisoning.—G. H. Whipple and S. H. Hurwitz, in the *Journal of Experimental Medicine*, report experiments on dogs and summarize their results as follows: Chloroform anesthesia for two hours or more will cause more or less central liver necrosis in dogs, depending on the length of the anesthesia and the susceptibility of the animal. If the fibrinogen of the blood of such an animal be estimated at intervals, it is found that this proteid shows a drop corresponding to the amount of liver necrosis. By administering chloroform, the fibrinogen may be almost eliminated from the circulating blood, and the poisoned animal may bleed for hours from small skin pricks or cuts. The liver can recover from a grave injury due to chloroform and return practically to a normal condition in about ten days. The fibrinogen reappears in the blood as the liver effects its repair. It seems that the quantity of fibrinogen present is a good indicator of the liver efficiency and a fairly accurate index of the amount of liver injury. Shortly after the recovery of the liver from an injury due to chloroform, one may find an excess of fibrinogen in the blood. In severe cases of chloroform poisoning, the calcium of the blood was normal or slightly increased, and the thrombin was normal. These experiments give no evidence that the formation of thrombin or prothrombin is dependent on liver activity. The hemorrhages of chloroform poisoning are due not to lack of blood clotting but to inefficient coagulation. The clot has not the body and toughness supplied by the fibrinogen, and is, therefore, unable to check even capillary hemorrhage. Fibrinogen is either formed in the liver or is wholly dependent on liver activity for its production.

Effects of Mechanical Agitation on Complement.—Under certain conditions, according to H. Noguchi and J. Bronfenbrenner, mechanical agitation destroys the complementary activity of guinea-pig serum. It is most injurious when carried out constantly at a temperature of 37 C., but it is extremely insignificant at 10 C. After the first few hours at 37 C., the destruction of complement proceeded much more rapidly, and after six hours it was almost complete. On the other hand, within one hour, shaking had almost no destructive effect on complement, even at 37 C. From this we may conclude that the several shakings which are necessary for fixation experiments during incubation do not modify perceptibly the outcome of the reactions. The rate of destruction of the complement of guinea-pig serum at temperature above 45 C. is progressively greater as it approaches 55 C., at which temperature the activity is reduced in thirty minutes to from one-thirtieth to one-fortieth of the original strength of the unheated serum; but it is not completely destroyed, as is commonly assumed. The velocity of destruction of guinea-pig complement when exposed to 55 C. for various lengths of time is found to be quite irregular, and not proportional to the length of time. This irregularity, however, presents a certain rhythm, a period of greater destruction alternating with one of less destruction.—*Journal of Experimental Medicine.*

Mercury Bichlorid and Serodiagnosis of Syphilis.—H. Noguchi and J. Bronfenbrenner have made experiments to ascertain what effects a soluble mercurial preparation will have on the syphilitic antibody *in vitro*. As a mercurial preparation, they chose mercury bichlorid; and for the fixation test, the system of Noguchi. The effect of bichlorid of mercury was determined on (1) red blood-corpuscles, (2) complement, (3) antihuman amboceptor (rabbit), (4) syphilitic antigen (acetone insoluble tissue lipoids of human liver), and (5) syphilitic antibody. The hemolytic power of bichlorid of mercury was considerably reduced by mixing it with 0.05 c.c. of guinea-pig complement or with two units of the amboceptor serum on paper, but was not noticeably diminished by the antigen, which was used in doses of 0.0003 gram. It has no anticomplementary effect. On the contrary, the hemolysis was more complete and proceeded more rapidly in its presence. This is due to the injurious effect of bichlorid of mercury on the corpuscles, thus reducing the corpuscular resistance to the hemolytic action brought about by the complement and amboceptor. In the highest non-hemolytic quantity (0.0000025 gram) bichlorid failed to remove, to a noticeable degree, the syphilitic antibody, and the reaction in two strongly positive sera remained unchanged.—*Journal of Experimental Medicine.*

Neurasthenia in Children.—The "nervous," or "neurotic" child is, like the poet, "born and not made." He is often the child of neurotic stock, or his origin may be traced to alcoholism, tuberculosis, ill-health or poverty in the parent. Neurotics generally abound in families in which great ability or genius predominate, but also in those in which insanity, epilepsy and other neuroses are found. According to Riviere, in the *Practitioner*, the hall-mark of the "neurotic" seems to be an over-development of the emotional faculties; at the other end of the scale stands the unemotional type," and necessarily all grades exist between these two extremes, so that the term neurotic may be qualified by "more" or "less," and, save in its higher grades, its possession may confer a blessing rather than a curse. To the higher grades of neurotic inheritance, however, a curse and a stigma attaches, and the penalty in sorrow and suffering greatly outweighs the reward, especially in childish years before the judgment comes into play.

Prognosis of Cerebrospinal Syphilis.—The prognosis of cerebrospinal syphilis is in general a serious one, owing to the frequency with which it resists treatment, and to the pronounced tendency to late recurrences and grave complications. Various factors affect the outlook. For instance, this is worse in cases in which the onset of the disease is many years after the infection, or in which other diseases or cachexias are present, particularly tuberculosis and alcoholism; it seems to be worse also in cases in which the early manifestations of syphilis were slight. Unfortunately there is not much reason to believe that thorough treatment in the early stages is a satisfactory guarantee against the later occurrence of cerebrospinal syphilis, but on the other hand energetic treatment at the onset of this certainly has an important influence on the course it will run.—E. Jones, in *Interstate Medical Journal.*

Cancer Investigation.—Experiment is rapidly advancing toward a stage at which the nature of cancer will be made clear, the influence of heredity, and of external factors, e. g., of all chronic irritants, defined; but a means of cure is not yet in sight. The only hope for the cancer patient still lies at present in the general practitioner being so suspicious of all lumps which cannot be explained that he will urge their removal as early as possible, and have them carefully examined by skilled microscopists. Here I would enter a protest against the snipping out of a little piece for diagnostic purposes, for experiment has shown how great is the danger of dissemination of cancer cells in the individual where they are "at home;" however difficult it may be to effect the transference of a cancer from one mouse, rat, rabbit or dog to another, the attempt always succeeds if the same individual be inoculated with his own tumor.—E. F. Bashford in the *Practitioner.*

Injection of Air in Treatment of Sciatica.—F. Ramond and his associates recently reported at the meeting of the Paris Société des Hôpitaux the results of different methods of treatment of sciatica as applied in sixty-five cases. Hypodermic injections of sterilized air were applied in thirty-three cases at the points where the pain was most intense, sometimes at the emerging point of the nerve, in the middle of the thigh, in the calf and occasionally a fourth injection at the sacro-iliac articulation. He injects about two-thirds of a liter of air at each point into the subcutaneous tissue, thus making a continuous emphysema from buttocks to ankle. The air is injected slowly and the relief from pain is immediate and usually constant; the pain returns, however, after eight or ten hours in the unsuccessful cases. The cure was permanent in four of the ten cases rebellious to other measures, and in thirteen of the twenty-three cases in which this was the first measure applied; four other patients were materially improved. A glass tube containing a little cotton is interposed in the rubber tube and bulb connected with the Pravaz needle. The only danger from this treatment is the possibility of air embolism, but this has never occurred, and it is easily prevented by injecting a little salt solution beforehand. If a little edema forms, this shows that the fluid has not entered a vein. The absence of blood if the syringe is pumped also shows that no vein has been entered. Ramond's conclusions from his experience with sciatica are that one method may succeed when all others fail, and that each should be given a trial.

Hematoma of the Adrenal Body.—This unusual case is reported by Case (*Proc. Path. Soc., Philadelphia*, December, 1910, p. 258), in a negress, aged 63, who was admitted to the Philadelphia General Hospital Dec. 29, 1909, and died Jan. 8, 1910. She suffered, while in the hospital, with mitral regurgitation, aphasia, paralysis of the left arm and incontinence of urine and feces. The most interesting finding at autopsy was the left adrenal which was about the size of a goose egg. It was dark red in color, with here and there patches of yellow, much divided and separated cortex, showing beneath the capsule. This enlargement involved approximately two-thirds of the organ, and was due to a comparatively old hemorrhage into the medulla, with here and there areas of fresh blood-clot. In addition, the microscope revealed a moderate proliferation of connective tissue about the clot, with thickening of the capsule. The kidney was arteriosclerotic and the aorta atheromatous.

Humidity in the Problem of Ventilation.—Air is more essential to life than food; good air is as essential as good food, and plenty of air has the same merit as plenty of food, says D. D. Kimball (*Annals American Academy of Political and Social Science*, March, 1911). In the process of respiration, oxygen is reduced in amount while the carbonic acid and water vapor are largely increased. Neither water vapor nor the carbonic acid, due to respiration, is injurious; but as an increase of carbonic acid in the air of an apartment is usually accompanied by a decrease in the amount of oxygen and an increase of water vapor, the percentage of carbonic acid is an index of the quality of the air. Apparently it is not altogether the chemistry of the air but its temperature, humidity, motion and, possibly, other physical properties unknown, which are the attractive features of outdoor air. It is becoming generally believed that when air contains a normal proportion of oxygen its temperature and humidity are of greater importance than the absence of carbonic acid. The proper control of the temperature of a room is not only conducive to health and comfort, but means a substantial saving in fuel. Headaches, dizziness, sickness, etc. are often symptoms of bodily heat retention due, chiefly, to high room temperature and lack of humidity. The relative humidity of outdoor air at other times than during storms varies from 50 to 80 per cent, and in the most arid desert is rarely as low as 30 per

Herbert Franklin Brethour, M.D. University of Toronto, 1899; of Hamilton, Mont.; died in a hospital in Butte, Mont., March 28, from septicemia, aged 34.

Arthur L. Kendall, M.D. McGill University, Montreal, 1901; of Vancouver, B. C.; died in the Vancouver General Hospital, Oct. 8, 1910, from typhoid fever.

Cain C. Godshaw, M.D. University of Louisville, Ky., 1874; fell from the window of his office in Louisville, April 3, and was instantly killed, aged 55.

Joseph B. Allen (license, Iowa, years of practice, 1886); a practitioner for sixty-five years; died at his home in Hillsboro, Ia., April 7, aged 88.

Lucius D. Huffman, M.D. Jefferson Medical College, 1885; died at his home in Covington, Ky., March 24, from chronic myocarditis, aged 56.

Samuel P. Goudy, M.D. Columbus (O.), Medical College, 1881; died at his home in Jamestown, Pa., March 17, aged 63.

Ingraham Bill Freeman, M.D. Jefferson Medical College, 1856; died at his home in Bridgetown, N. S., February 27.

Alexander C. Scott, M.D. Savannah (Ga.) Medical College, 1867; died at his home in Jacksonville, Fla., March 11.

Gideon Barnaby, M.D., Harvard Medical School, 1872; died at his home in Granville Ferry, N. S., January 10.

J. S. Wilson, M.D. Kentucky School of Medicine, Louisville, 1879; of Macy, Ind.; died at Peru, Ind., March 10.

Franklin Winger, M.D. Jefferson Medical College, 1886; died at his home in Ephrata, Pa., March 15, aged 47.

"The Propaganda for Reform"

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

BENETOL

During the last few months sensational and ridiculously misleading articles have appeared in the daily press regarding a proprietary preparation called Benetol. The nostrum seems to be advertised by the direct method only to physicians; to the public it goes via the special newspaper article route, as a "marvelous medical discovery." It is but fair to say in this connection, that the newspapers which have published these articles seem to have done so in good faith and in total ignorance of the fact that they were giving the Benetol Company a large amount of free advertising. It is evident that the press agent's work was well done.

Here are a few claims that are made, either to the medical profession or to the public, for Benetol:

> "A new germicidal antiseptic marvel."
> "The only safe germicidal antiseptic."
> "It will cure any germ trouble it can reach."
> "Is beneficial rather than dangerous in overdoses."
> "The only germicide that can follow and kill germs."
> "A laboratory product of the University of Minnesota."
> "A chemical which destroys the germs of tuberculosis, typhoid and cancer."
> "Ten drops allowed to remain a short time in a gallon of infected water will make the water not only safe to drink, but will make it beneficial as a medicated water."

In the newspaper write-ups on Benetol, its discoverer is given about the same degree of publicity as the drug. Benetol is said to have been "dicovered" by "Prof. H. C. Carel, Head of the Department of Medical Chemistry and Toxicology, University of Minnesota (Retired)."

In many of the newspaper articles it is implied that Carel is still a member of the faculty of the University of Minnesota. The facts are, Carel has not been connected with this institution for some years. His connection with the university ceased at the time he exploited a hair restorer—"Hygenol." In selling his cure for baldness, he attempted then, as he is attempting now, to make capital out of the good name of the university—and the board of regents saw to it that Carel's connection with the university was severed. The attempt, therefore, to exploit Benetol as "a laboratory product of the University of Minnesota," is both an outrage on an institution of learning and a fraud on the purchaser.

In one of the *press-agent notices* on Benetol, the claim is made that the War Department has investigated Carel's "New Discovery" and that the heads of the department have *urged the government* to secure the "sole information and ownership" of Benetol. As a clincher it goes on to say:

> "An emissary is being sent to Prof. Carel to enter into negotiations, and for the first time in its history the United States government may go into the germicide business."

An inquiry at the War Department, regarding the veracity of the statements given in the exploitation of Benetol, brought the following statement from the office of the surgeon-general:

> "As you have surmised, there is no foundation of truth in the statement which you inclose with reference to the use of 'Benetol' by the medical department of the Army. This office has not authorized the purchase of any 'Benetol' nor has it investigated its merits."

DEATH TO GERMS, LIFE TO HUMAN BEINGS

Greatly reduced photographic reproduction of a full-page newspaper write-up of Benetol. Under the portrait of the "inventor" of Benetol appears the statement "Prof. Herbert Charles Von Fuerstenburg Carel, of the University of Minnesota, the inventor of Benetol." This write-up appeared in the Philadelphia North American, a paper that treats "patent medicine" fakers with scant courtesy. It was the appearance of such an article in a paper of this type that caused us to investigate the method by which the exploiters of Benetol got their product into the newspapers in this form.

Nor was the army alone the only department of the government that was credited with waxing enthusiastic over Carel's nostrum. It was claimed that the stuff had been tested in the navy. An inquiry addressed to the Bureau of Medicine and Surgery of the Department of the Navy brought the following statement:

> "This Bureau has never issued 'Benetol' for use in the Navy and does not contemplate doing so, having no knowledge of, nor interest in, this preparation."

In view of the claims that have been made for Benetol its composition is a matter of interest. What is this marvelous germicide; this "chemical," which destroys the germ of cancer; this wonderful discovery which "for six years Prof. Carel toiled night and day" to produce; this potent typhoid destroyer, 10 drops of which in a gallon of infected water will make the water not only safe but beneficial; what is this new medical wonder? This inquiry was referred to the director of the Association's Chemical Laboratory and secretary of the Council on Pharmacy and Chemistry, who replied:

"Chemical examination of benetol shows that it is a solution of alpha-naphthol containing about 18 gm. of the substance in 100 c.c. The solvent appears to consist of water, glycerin and soap. Alpha-naphthol is a well-known substance, closely related to, but not identical with, beta-naphthol which is official in the United States Pharmacopeia. The claim made in the advertising matter for Benetol, that it is a newly discovered compound is absurd. It is not a chemical compound, but a simple solution of the well-known substance alphanaphthol in the still better-known substances, glycerin, soap and water."

Treatment by New Remedies

In his new "Pocket-Book of Treatment," Ralph Winnington Leftwich, M.D., has the following to say about "the very latest" in therapeutics:

"The young practitioner purrs when he is told he is up to date. When he becomes more experienced he will have discovered that it is safer to be, say, six months behind the times. In fact, the up-to-date physician may be defined as a man who experiments on his patients. Leaving on one side remedies which are introduced to the profession for purely commercial reasons, a new remedy, or a new application of an old one, is to its discoverer what a new baby is to its mother—wonderful and unparalleled! In both cases, and without any dereliction from good faith, the judgment is biased. The remedy is introduced with a fanfare of trumpets loud in proportion to the status of the originator. Chemists [druggists] stock it, and other manufacturers not only imitate it, but puzzle their brains in coining fresh trade-marks which they hope will induce the public to think that theirs is the real original product, *et puis bon soir!* For, twelve months afterward, it is forgotten by all but the exasperated chemists [druggists] who have stocks of it left on hand. Sometimes, as in the case of a well-known preparation of arsenic, it is found to be downright dangerous.

"No, except for incurable cases, it is time enough to prescribe a preparation when it has stood the test of ample independent trials. Let others do the experimenting. New preparations are sometimes made in this way: A manufacturer, running his eye down a book on therapeutics, finds, perhaps, seven different drugs recommended for a certain disease. He makes a kind of canister-shot by combining the whole of them under a trade-mark name, introduces it to the profession, and gets it more or less widely recommended. He then feels strong enough to spend thousands on advertising it to the general public, and the latter complacently dose themselves with it. Such preparations must be left severely alone; for every physician should be equal to making any necessary combinations in a prescription. A proprietary medicine is like a ready-made suit: a prescription is 'made to measure.'

"In a different and often very useful category, are some of those synthetic products which, based on sound chemical reasoning, are tested first on animals and later only on patients."

Correspondence

Uncinariasis in Students in Texas

To the Editor:—THE JOURNAL, March 18, 1911, contains the following erroneous statement under the heading of "Medical News":

"Recent investigations among the students of the medical branch of the University of Texas, at Galveston, revealed the fact that 43 per cent. of the students are afflicted with uncinariasis."

In 1901, while Dr. Allen J. Smith was professor of pathology in the University of Texas, he examined the stools of eighty-six students in this institution and found eight of them, or 9.3 per cent. of the number examined, infested with hookworm. He described these results in full in his paper on "Uncinariasis in Texas" published in the *American Journal of the Medical Sciences* for 1903, Vol. cxxvi, pp. 768-798.

Last year, Dr. James Greenwood, Jr., demonstrator of medicine, in the routine laboratory course in clinical medicine, requested those members of the junior class who found an excess of eosinophils in their blood to have their stools examined. He found six cases of uncinariasis in a class of fifty-six. During the present session, he made a similar request but found only one case among forty-four students. He did not examine the stools of all of these students, but only of those who had eosinophilia. He has never found uncinaria without eosinophilia, although the latter may exist in other conditions than uncinariasis. This gives an average of seven cases of uncinariasis among 100 students examined by Dr. Greenwood, which is about the same ratio as that found by Dr. Smith.

It is of special interest that in no one of these seven cases found by Dr. Greenwood had the individual any symptoms which would cause him to suspect that he had intestinal parasites or any condition affecting the general health. The parasites were found by accident in a routine examination. In one case, there were some anemia and emaciation, which conditions improved after successful treatment. In the others, the general health and nutrition had not suffered.

On the same page of THE JOURNAL is the following statement:

"The Medical College of the University of Texas, at Galveston, is asking the legislature to grant the use of the quarantine fees at Galveston for the establishment and maintenance of a hospital in connection with the quarantine station at that point."

This statement is in danger of creating the misapprehension that a request has been made to use the quarantine fees for the current fiscal year, or for fees that may be collected in the future.

A bill was introduced in the last legislature providing for the transfer of a balance in a special quarantine fee fund at Galveston, amounting to about $13,000, to build pavilions for isolating and handling cases of contagious diseases. This fund was created in 1907 for building a residence for the state quarantine officer and repairing the quarantine station at Galveston. The balance remained after the completion of the improvements contemplated in the special appropriation of 1907 and could not be diverted for any other purpose except by act of the legislature.

WILLIAM S. CARTER, Galveston,
Dean of the University of Texas.

Nail in Chicken Gizzard

To the Editor:—The following account may prove of interest:

I have before me, on my desk, a dried chicken gizzard which has been opened and cleaned in the usual manner. Through the thick part of one half is a round aperture, 1/8 of an inch in diameter—in the dried specimen—at the internal opening and 1/4 of an inch in diameter on the external surface. Through this aperture extends a six-penny box nail, its head being on the internal surface of the gizzard. The head of the nail and the portion of it within the wall of the viscus are much corroded.

The history of the curiosity, given me with the specimen, is as follows:

The fowl from which the organ was taken was one of a flock of three dozen slaughtered at the age of about five months. Under ordinary observation with the rest of the flock no signs of indisposition had been noted, this fowl coming with the rest to each feeding and behaving in a normal manner. When slaughtered it was found, however, to be "light and poor" instead of fat as were the others. When opened for cleaning the bowels were found to be "black" and covered with a dark, thick fluid. The liver was hard and "black," there were adhesions about the "gizzard," and the nail was visible, protruding through the wall of the viscus about "3/4 of an inch."

To me the points of interest are the facts that the fowl could have swallowed the nail in the first place; and that it could have survived resulting injury so long without greater disability, for that the nail had been present for some time is evidenced by the degree of emaciation of the fowl and the extent of corrosion of the nail—granting that the nail was not previously corroded, which from the appearance of the specimen is a possibility only.

H. LA MONT YOUTZ, Willow City, N. Dak.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

FETAL HICCUP

To the Editor:—Please give me the etiology, and significance, with relation to viability, of fetal hiccup. Also give me the references to articles bearing on fetal hiccup and other fetal movements.

I have a patient in the thirty-sixth week of a second pregnancy who directed my attention to a regular throb, beat or tap produced by the fetus; it is strongest in the region of the mother's navel, occurring with remarkable regularity about eighteen times a minute, and occurring about half the time, both day and night. Along with this throb are the other fetal movements—squirming, leaping, etc. The first pregnancy in this patient was normal in every way, and the baby normal for the first forty-eight hours, after which convulsions began, ending in death after six hours. The cause of these convulsions has never been clear to me nor to the men associated with me on that case, unless they came from some cerebral trauma during birth. The mother is very anxious for a child and more than usually apprehensive over abnormal conditions, and therefore called my attention to the throbbing described above.

It was new to me, and I found no enlightenment either from questioning my multiparous patients, or in the authorities, except in Edgar. In his second edition, discussing "quickening," p. 130, he says: "Among fetal movements should be included fetal hiccup." I did not find elsewhere in his book any explanation of fetal hiccup—hence my inquiry. "Fetal hiccup," if it were a true name, would seem to me to be a dangerous phenomenon—for hiccup means contraction of diaphragm muscles followed by inspiration. If a fetus really hiccuped wouldn't it draw in amniotic fluid, and by constant repetition completely fill the lungs with fluid, and therefore be drowned before having had a chance to breathe?

R. H. Brooks, Claremont, N. H.

Answer.—During the last twenty years several writers have reported cases of fetal hiccup. The movements that have been ascribed to hiccup-like contractions of the fetal diaphragm have been noticed in the latter part of pregnancy and generally can be felt by the mother. They are felt as sharp, quick impulses, about fifteen to twenty a minute, and lasting usually for a minute or two, when a quiet interval occurs. Sometimes they continue uninterruptedly for ten minutes The impulse can be felt by the hand placed on the abdomen and heard by the ear or phonendoscope. They are generally best heard in one of the lower uterine quadrants over the chest of the child. Ahlfeld, who has studied these movements with a kymographion and made numerous investigations, believes that they are more frequent in the early part of pregnancy and can be heard even before the heart-tones.

The cause and significance of this phenomenon are related to the question of fetal respiratory movements, which has been studied by Ahlfeld. The best discussion of this subject, as well as that of singultus, is in a paper by him in the *Monatsschrift für Geburtshülfe und Gynäkologie*, 1905, page 143, in which references to the cases reported up to the date of the article are given. Ahlfeld finds regular movements of the child which register on the kymographion from sixty to eighty a minute, which he holds must be due to fetal respiratory movements. The object of these movements is the preparation of the respiratory muscles for their function, which is exercised as soon as the child is born. The respiratory movements also help in the development of the ribs and the joint surfaces connecting them with the spinal column. Preyer in his "Physiology of the Embryo" says: "The new-born moves itself immediately after birth as it was accustomed to move before birth, with the exception of breathing and trembling." Ahlfeld completes this law as follows: "The new-born child makes only such movements as it has already made in the uterus. These movements are, of course, modified by the changed condition of the new-born." Ahlfeld regards the usual physiologic fetal inspiration as only superficial, as that is all that is necessary to the development of the respiratory organs. Probably the inspired fluid does not reach beyond the bifurcation of the trachea. How fetal hiccup is related to fetal respiration, and also how it is related to the common post-natal hiccup, Ahlfeld does not attempt to explain. He believes, however, that it occurs as a physiologic function of the diaphragm in practically all persons. Ahlfeld's theory of intra-uterine respiration and singultus has not been generally accepted, nor has it been satisfactorily refuted.

FORMULAS FOR ASTHMA REMEDIES

To the Editor:—Please give me a formula for an asthma remedy to be ignited under a paper cone or other convenient apparatus, and inhaled by the patient. There are a number of so-called asthma cures on the market, all of which have a similar composition (lobelia, stramonium, digitalis, hyoscyamus, tobacco, potassium nitrate, etc.), and one afflicted with asthma sooner or later finds one that affords him temporary relief. Kindly refer me to some work where I can find the formulas that have given the greatest satisfaction.

M. H. Farmer, M.D., Virden, Ill.

Answer.—A French asthma cigarette contains the following ingredients (Yeo):

Belladonna leaves	5½ parts
Hyoscyamus leaves	2¾ parts
Stramonium leaves	2¾ parts
Phellandrium aquaticum	1 part
Extract of opium	⅛ part
Cherry laurel water	a sufficiency

The dried leaves are cut small, mixed well and moistened with the opium which has been dissolved in the cherry laurel water. A small amount of potassium nitrate is added in order that the cigarettes may burn readily.

Some patented preparations contain lobelia, and something similar to Himrod's "cure" is as follows:

Powdered lobelia.
Powdered black tea.
Powdered stramonium leaves, each 1 ounce.

On this is poured 2 ounces of a saturated solution of potassium nitrate, which is thoroughly mixed and allowed to dry (Yeo). Portions of this are then burned and the patient inhales the fumes.

℞.

	gm.		
Potassii nitratis	15		
Pulveris anisi	15	or āā,	℥ss
Pulveris stramonii	30		℥i.

M. et fac pulverem.

Sig.: Ignite a thimbleful of the powder and inhale as directed. (The Journal, Jan. 2, 1909, p. 51.)

℞.

Pulveris belladonnæ foliorum	
Pulveris hyoscyami foliorum	
Pulveris stramonii foliorum	
Potassii nitratis	āā℥i.

M. et sig.: *Half a teaspoonful to be burned at one time.*

℞.

Stramonium leaves	ʒiv
Green tea	ʒiv
Lobelia	ʒjss

Mix and pour on the mixture enough saturated solution of potassium nitrate to wet it. Dry it and keep in closely stoppered bottle.

℞.

Daturæ tatulæ	ʒij
Stramonii foliorum	ʒij
Cannabis indicæ	ʒij
Potassii nitratis	ʒij
Olei eucalypti	ʒss

Mix thoroughly.—(An Index of Treatment: Hutchinson and Collier, p. 80.)

Cigarettes made of paper soaked in a solution of nitrate of potassium and belladonna may be smoked or they may be made in the following manner:

℞.

Belladonnæ foliorum	40	gr. vj
Hyoscyami foliorum	2	gr. iij
Stramonii foliorum	2	gr. iij
Extracti opii	015	gr. ¼
Aquæ laurocerasi		q.s.

M. These various leaves are broken up like commercial tobacco and moistened by adding the cherry-laurel water, which should contain the opium. Finally, a whole leaf soaked in the same fluid is used as a cover, or a piece of cigarette paper may be employed in the same manner. (Hare's Practical Therapeutics, p. 619.)

LITERATURE ON MUNICIPAL SANITATION

To the Editor:—Can you give me information or cite literature on the subject of municipal sanitation? I am particularly desirous of suggestions as to some method of dealing with stables and stable manure in order to diminish the propagation of flies.

C. A. Woodard, Durham, N. C.

Answer.—As is well known, stable manure is one of the most frequent breeding-places for flies, and probably the most practical method of preventing them from propagating would be stringent regulations requiring the daily cleaning of stables and the storing of the manure in closed or carefully screened bins, with frequent removal of the manure.

The prevention of flies in cities, of course, involves the prevention of the accumulation of other sorts of waste, including garbage, in which flies may breed. Numerous editorials and articles have appeared in The Journal concerning flies as carriers of disease, and their prevention, and on other phases of municipal sanitation. A list of these, together with some books on municipal sanitation and hygiene, will be found below:

Editorial: Abating the Fly Nuisance, The Journal, Aug. 20, 1910, p. 700; this issue of The Journal also contains an editorial on the hypochlorite method of purification of water and refers to an article on this subject (Paper 229; U. S. Geological Survey, 1909).

FETAL CIRCULATION

To the Editor:—1. What causes the pulse-wave in the umbilical cord? 2. Is this wave toward or from the child? 3. Is the circulation of the fetal blood caused by the fetal heart or is it *maternal*? 4. Does any maternal blood enter the fetus? 5. Can the placental souffle be heard after the death of the fetus?

Antonio D. Young, Oklahoma City, Okla.

Answer.—1. The pulse-wave in the umbilical cord is caused by the beating of the fetal heart.

2. The pulse-waves are essentially arterial impulses and pass from the heart to the periphery along the arteries. Therefore the pulse of the umbilical cord is in the artery and the wave passes from fetus to placenta, "from the child."

3. The circulation of the fetal blood is caused solely by the contractions of the fetal heart.

4. No maternal blood enters the fetus. The maternal blood circulates through sinuses of the placenta, bathing the villi within which the fetal blood circulates. Through the thin-walled membrane of the villi the oxygen of the maternal arterial blood diffuses and combines with the hemoglobin of the fetal blood, after which it returns to the fetus through the umbilical veins. It may be said in passing that the umbilical artery carries impure blood from the fetus to the placenta, where it is purified first through the loss of carbon dioxid, and, second, through the diffusion of waste products into the maternal blood, where it is oxygenated as described above and replenished by the diffusion of food materials from the maternal blood into the fetal blood.

5. The placental souffle or murmur is sometimes called the uterine souffle and is heard over the site of the placenta. It might be mentioned that the uterine souffle may also be heard over uterine fibroids, which fact necessitates some care in discriminating between a fibroid tumor and pregnancy. The placental souffle may be heard after the death of the fetus. The term "souffle" is also applied to a murmur that is heard in the umbilical cord. This is called the fetal souffle. If the cord should become looped around the neck or leg of the fetus, and thus become constricted, a souffle may be heard. This fetal souffle, due to the pulsation of fetal blood through a constricted segment of umbilical cord, will of course cease the moment the fetal heart ceases to beat.

ACUTE TONSILLITIS

To the Editor:—1. What are the causes of *acute tonsillitis*?

2. What is the proportion of cases due to non-microbic factors?

3. Is the ordinary iron mixture or any astringent beneficial in the acute stage, or should the use of such preparations be confined to the later stage in which the tonsils have been freed of all exudate?

4. What is the pathology of the white cheesy exudate?

By answering these questions you will help me to understand an illness which is common but not entirely clear to me.

Samuel Levine, M.D., Brooklyn.

Answer.—1. The principal causes of acute tonsillitis are exposure to cold and sudden thermic changes, especially in persons of rheumatic diathesis. Tonsillitis is frequently associated with menstruation. Among other causes, we may mention traumatism such as irritating fumes and vapors. Predisposing causes are nasal or postnasal irregularities, general lowered systemic tone, and various gastro-intestinal disturbances.

2. A definite answer cannot be given. There are a great number of microbes in the fauces continually, either in well or ill people. What the influence of these microbes may be in the development of the inflammation has never been definitely determined.

3. The iron mixture and other stimulating or astringent applications are often beneficial in the early stages of the disease, more so than in the later stages. In the late stage, tonics are useful. In the early stage, the inflammation may sometimes be aborted by stimulating applications. The most satisfactory consists of equal parts of guaiacol and almond oil to be used as a spray once a day. This causes intense burning for about a minute, but afterward gives great relief from pain for hours and in a considerable percentage of cases, will materially cut short the attack.

4. These cheesy masses consist of fibrinous exudate, necrotic epithelial cells, bacteria and the earthy matter from the ordinary secretions of the tonsils.

REMOVAL OF FOREIGN BODIES FROM THE CONJUNCTIVA

To the Editor:—I recently ran across an extraordinary statement in Berry's "Manual of Practical Ophthalmology," Lippincott, 1905. It is part of the subject matter "Foreign Bodies in the Conjunctiva" page 132. Speaking of removing them the author says: "Attempts at removing them, without eversion, with a camel's hair brush or the tip of the tongue passed below the upper lid, should not be made."

Such surgical technic is beyond my comprehension or imagination. Why a modern text-book should have such stuff incorporated in its text goes beyond me.

W. L. Moore, *Honolulu, H. T.*

Answer.—The removal of foreign bodies from the external ocular apparatus by the laity as well as by some members of the medical profession is, to say the least of it, often an extraordinary procedure. In certain countries the attempt by the former to dislodge foreign substances from the conjunctival sac with the tip of the tongue is a common experiment, while the camel's-hair brush is not infrequently employed (beneath the uneverted lid) by inexperienced physicians for the same purpose. Consequently Berry's reference is to some extent apropos, although he might have elucidated the rather obscure allusion to these attempts.

A layman realizes, of course, that the important thing is to remove the foreign body. In the process, however, considerable damage is often done to the conjunctiva. It might be well for the laity to know the value of a saturated solution of boracic acid, which is very soothing after a foreign body has been taken from the eye. It has most of the merits of the many eye nostrums on the market, as boric acid is the chief constituent of many of them. Such a solution is kept on hand in many households, and it ought to be a more common adjunct of the family medicine chest. It would help to alleviate the trauma often caused by well-meaning but unskilful attempts at removing the offensive foreign body.

SODIUM GLYCOCHOLATE AND CHOLESTERIN TESTS FOR SYPHILIS

To the Editor:—Please give me information about sodium glycocholate and cholesterin tests for syphilis or tell me where I can procure the desired information, including the technic.

J. D. Rueng, M.D., San Francisco.

Answer.—The tests referred to have not proved specific and, we believe, are now generally abandoned. Descriptions of them may be found in the articles by W. J. Butler, "Serum Diagnosis of Syphilis," The Journal, Sept. 5, 1908, p. 824, and "The Serum and Precipitate Reactions for Syphilis and Their Clinical Value," The Journal, April 2, 1910, p. 1115. POEHL'S SPERMIN IN ARTERIOSCLEROSIS

To the Editor:—In a recent number of the *Gazette méd. belge*, xxi, No. 43, p. 424, I read a detailed report of five cases of arteriosclerosis in which the patients were all markedly improved and some of them apparently cured by a course of "Sperminum Poehl," an advertised remedy which I have always distrusted and never prescribed. I am now suffering myself from a somewhat advanced case of arteriosclerosis and would like to try this remedy if the Council has learned anything in favor of it and if there is no reason to fear bad effects from it.

X. Y. Z.

Answer.—Apparently the exploitation of Poehl's spermin passed several years ago from the domain of experimental medicine to that of nostrums advertised to the laity. So far as we know, it has received no recent discussion from reliable clinicians or experimenters. In some medical journals, as also in lay journals, it is true, one still reads that Poehl's spermin is successfully applied in "neurasthenia, senile marasmus, anemia, rachitis, gout, chronic rheumatism, syphilis, hysteria, tuberculosis, typhus, diseases of the heart, nephritis, tabes dorsalis, paralysis, neurasthenic impotence, overwork, acute diseases, and for convalescents." Few quack advertisements would differ much from this puff of Poehl's spermin. So far as we know, there is no reason to fear injurious results from the use of the remedy; neither might any good be expected from its use in arteriosclerosis.

The Public Service

Medical Department, U. S. Army

Changes for the week ended April 8, 1911.

Thomason, Henry D., captain, ordered to proceed to Jefferson City, Mo., on official business relative to the reorganization of the sanitary troops of that state.

Chase, Chauncey L., M.R.C., ordered to active duty and assigned to station at Fort Oglethorpe, Ga.

Davis, Arthur O., lieut., ordered to proceed from Fort Oglethorpe, Ga., to San Antonio, Texas, for duty with maneuver division at that place.

Wales, Philip G., M.R.C., reported for temporary duty at Fort Miley, Cal.

Bourke, James, captain, in addition to his duties at Fort Crockett, Texas, will report to the commanding general, first separate brigade, for duty as medical supply officer of that brigade.

Wing, F. F., D.S., reported for temporary duty at Fort Robinson, Neb.

Bourke, James, captain, will, in addition to his other duties, perform the duties of medical superintendent, transport service, at Galveston, Texas.

Moncrief, William H., captain; Pyles, Will L., captain; Casper, Joseph, lieut., and Sherwood, Joseph W., M.R.C., will proceed to Galveston, Texas, and report to the commanding general, first separate brigade, for duty.

Nichols, Henry J., captain, detailed to represent the medical department of the Army at the eighth annual meeting of the American Society of Tropical Medicine, New Orleans, May 18 and 19, 1911.

Craig, Charles F., captain, will proceed to Montgomery, Ala., for the purpose of delivering a lecture, April 18, before the medical officers of the Alabama National Guard on the subject of malarial disease.

Le Hardy, Julius C., M.R.C., on completion of such duty assigned him by commanding general, department of California, will proceed to Fort Ward, Wash., for duty.

Medical Corps, U. S. Navy

Changes for the two weeks ended April 8, 1911.

Haynes, J. P., P. A. surgeon, ordered to the naval station, Olongapo, P. I.

Huff, E. P., asst.-surgeon, detached from the naval hospital, Canacao, P. I., and ordered home.

Michaels, R. H., A. A. surgeon, ordered to the marine recruiting station, Chicago.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended April 5, 1911.

Wasdin, Eugene, surgeon, placed on "waiting orders," effective Sept. 22, 1911.

Cumming, H. S., surgeon, directed to proceed to Fisherman's Island, Va., on special temporary duty.

Foster, M. H., P A. surgeon, directed to proceed to Bureau for consultation. Relieved from duty at Ellis Island, N. Y., and directed to report to the commissioner of education, department of the interior, for duty in Alaska. Granted seven days' leave of absence from April 3, 1911.

Billings, W. C., P. A. surgeon, directed to proceed to Ellis Island, N. Y., and report to the chief medical officer for duty.

Earle, B. H., P. A. surgeon, leave of absence for thirteen days from March 1, 1911, amended to read "ten days from March 2, 1911."

Chapin, C. W., asst.-surgeon, granted seven days' leave of absence from March 22, 1911, under paragraph 191, Service Regulations.

Draper, W. F., asst.-surgeon, directed to report to the commanding officer of the Revenue Cutter *Bear* for duty.

Schwartz, Louis, asst.-surgeon, directed to proceed to Seattle, Wash., and report to the commanding officer of the Revenue Cutter *Tahoma* for duty

Moorer, M. P., A. A. surgeon, granted ten days' leave of absence from March 28, 1911.

Story, H. C., A. A. surgeon, granted thirty days' leave of absence from May 1, 1911.

Board of medical officers convened to meet at the Marine Hospital office, customs house, New Orleans, on April 3, 1911, for the physical examination of candidates for appointment as cadet-engineer in the Revenue-Cutter Service. Detail for the board: Passed Assistant Surgeon A. D. Foster, chairman; Acting Asistant Surgeon J. T. Scott, recorder.

Medical Economics

This Department Embodies the Subjects of Postgraduate Work, Contract Practice, Legislation, Medical Defense, and Other Medicolegal and Economic Questions of Interest to Physicians

INDUSTRIAL DISEASES AND PHYSICIANS

JOHN B. ANDREWS

Secretary, American Association for Labor Legislation

NEW YORK CITY

The average American feels the magnitude of the national growth; he sees something of the result of the combined labor of millions of workers; he realizes, to some extent, that his country has leaped into the van of civilization, and he believes implicitly in his country and in himself. But the average man is an empirical observer. So far as mere physical achievement goes, he sees aright. His perception of the magnitude of individual and national effort, his knowledge of the volume of production, is right. But he fails utterly to understand that the tremendous social forces that have been evolved, and that have made these things possible, have necessarily wrought profound changes in social relations, in social needs, and in the relations of the individual to society.

Of all professional men, perhaps the most definitely social in his service is the physician. His duties bring him into the most important and intimate human relations. His knowledge is purchased only by many years of highly specialized training, and the medical profession, as a natural result, becomes the guardian of the public health. The average modern man does not stop to reflect that he is impossible without the physician, who attends his entry into the world, keeps him in it as long as is humanly possible, and in the end sees him out of it.

But the contrary is equally true, for the physician is possible only because of the modern man, to understand whom the physician needs a clear knowledge of his patient's normal environment, and this the physician does not require as part of his necessary training. An examination of the overcrowded medical curriculum gives no indication of the fact that we live in an industrial society. The result is that a large percentage of physicians fail to realize the occupational source of many diseases, as has been shown by investigations.

An enormous range of diseases is directly attributable to the patient's work. The disease is contracted by him as an immediate result of his occupation, or his occupation produces conditions that foster the contracting of diseases, such as tuberculosis, neurasthenia and anemia. The bald statement of this fact is but a truism, known more or less definitely to every physician. It assumes vast proportions, however, when it is clearly recognized that the population of our country is a working population, and that there are few if any occupations that a man or woman may follow that do not, without careful regulation, produce sickness in one form or another, or contribute conditions that make the worker liable readily to contract disease from which he would ordinarily be immune.

The conditions under which the people of this country work produce in their aggregate the problem covered by the term "industrial hygiene," a problem of comparatively recent recognition among us. We have been so busy making profits that we have had no time to inquire how they are made or what their making entails. We are therefore obliged to go abroad to countries that have studied the subject in order to acquire scientific foundations on which to base our plans for improvement.

Germany and Great Britain have, perhaps, done more than other countries in this direction; and, characteristically, the German investigations are the more complete and systematic.

For want of American data we may base our estimates of the extent of sickness due to occupational conditions on the careful results of German experience. That experience shows that the number of cases of actual sickness is equivalent to 40 per cent. of the number of persons exposed to risk. If, therefore, we take the number of persons engaged in gainful occupations in the United States in 1910 as 33,500,000, we may present the following table, taken from the Memorial on Occupational Diseases presented to President Taft on September 29 last:

ESTIMATE OF SICKNESS AND ITS COST AMONG OCCUPIED MALES AND FEMALES IN U. S., 1910 (33,500,000)

(a) Estimated number of cases of sickness on the German basis of 40 per cent. of the number of persons exposed to risk, 13,400,000.

(b) Estimated number of days of sickness on the German basis of 8.5 days per person *per annum*, 284,750,000.

(c) Estimated loss in wages at an average of $1.50 a day for 6/7 of the 284,750,000 days, $366,107,145.

(d) Estimated medical cost of sickness at $1 a day for 284,750,000 days, $284,750,000.

(e) Estimated economic loss at 50 cents a day for 6/7 of the 284,750,000 days, $122,035,715.

(f) Total social and economic cost of sickness *per annum*, $772,892,860.

(g) Estimated possible economic saving in the health of individual workers on a basis of 25 per cent. reduction *per annum*, $193,223,215.

Objection to these figures may be urged on account of the differences that exist between industrial conditions in Germany and in America. The differences are admitted; but the figures here given would beyond doubt have to be increased on every count.

This country's industry is, to a large extent, innocent of the devices long in general use abroad, and particularly in Germany, for safeguarding the health of the workers. The occasional voluntary efforts of employers are far too spasmodic and unscientific to be regarded as important factors in this connection. The body of factory legislation in America is also pitifully slight, and noteworthy in the main for its lack of scientific knowledge and method. And, when even poorly conceived laws are enacted, the machinery provided for their enforcement is ludicrously insufficient. Industrial regulations in America, as they affect the health of the workers, are as unscientific and chaotic as in any country in the world that claims to possess the elements of western civilization. We have each year about 500,000 industrial accidents, one-half of which might be prevented. We have in our midst every year at least 13,500,000 cases of industrial sickness, involving a loss to society of $772,892,860, and of all this loss we can save at least 25 per cent.

We have, then, to devise means for securing accurate and complete information on the incidence of industrial disease. On this immediate and preliminary necessity, Professor Charles R. Henderson said recently, speaking at the fourth annual meeting of the American Association for Labor Legislation at St. Louis:

> In the social conflict with communicable diseases (scarlet fever, diphtheria, etc.), reports to health authorities are found essential to success. Hidden disease works all the greater damage because it is in the dark. What is brought to light can be fought in the open.
>
> The same is true of occupational diseases. So long as their nature, ravages, causes are concealed, the medical profession is deprived of information it needs, workmen die in ignorance of what kills them, public sentiment on the subject does not exist, legal regulation is not enacted or not enforced.
>
> It is now generally recognized that the members of the medical profession have a special duty to the community in the matter of reporting diseases and facts for vital statistics. They alone have the information; they have received much of their education at public expense in public or endowed schools, laboratories or hospitals; and they are supported by the public; they are excused from various duties which fall to other citizens.
>
> If they neglect this professional duty, misery and death will result. If they make their reports as perfect as possible, science will be advanced, legislation will be wiser and more effective, and public wealth and happiness will be increased. How many physicians recognize the occupational origin of certain diseases? The investigations of the Illinois Commission on Occupational Diseases have disclosed the unfortunate fact that many physicians do not know the shop origins of certain maladies.
>
> The records of death in the offices of health authorities, coroners, the records of public hospitals, of insurance associations, even when made by medical men, yielded but little information as to the working place and its conditions, the essential matter.
>
> Various diseases of the central nervous system, muscular and respiratory systems give very little direct clue to the causes of such disorders.

The statistical and other precise information that would be made available by the systematic reporting of cases of disease due to occupation would be of the utmost value, and, indeed, would be essential to intelligent action. But the mere classification of diseases does not provide a means for their elimination or diminution. It is necessary that the influence of the physician be felt in the actual place of work.

Adequate factory and workshop inspection is essential, and while it is true that in many branches of this work non-medical men are quite competent, in some of the most vital branches medical men are essential. "Medical men alone," said Dr. William C. Hanson, of the Massachusetts Board of Health,[1] "are in a position to make the best use of facts obtained concerning the sanitary condition of premises where men and women work; to study the possible injurious effects of certain injurious processes on the health of the person engaged therein; to inspect devices designed to protect the employees against injurious and dangerous substances, and to judge of the effects on the health of operatives of such substances, as well as to detect pathologic signs or symptoms of certain poisons, dusts and fumes incident to some occupations; to inquire as to the health of employees, both for the purpose of aiding those found in ill-health or physically unfit for work, and for protecting others from infectious diseases; to make physical examination of minors, and, whenever possible, of adults engaged in trades or occupations deemed to be injurious to health; and to collect and make proper use of all facts and data, including morbidity and mortality statistics, pertaining to occupational hygiene."

It is frequently urged in opposition to the demand for such efficient factory inspection and the necessary legislation, that conditions in America are not nearly so bad as in Europe, and that, in any event, European conditions cannot be regarded as giving a clue to conditions in America. That, however, is mere childishness. No reasonable human being could take seriously the argument that although lead poisons English workers or German workers it does not necessarily poison "American" workers. Such beginnings of scientific investigation as have been conducted in America give us a picture of conditions that constitute a widespread and persistent menace to the national health.

Thus the investigation into phosphorus poisoning in the match industry, carried out in cooperation with the United States Bureau of Labor, produced facts that call for immediate Federal legislation. An intensive investigation in the homes of the workpeople of but three of the sixteen American match factories yielded a total of eighty-two cases of phosphorus poisoning. Detailed investigation in fifteen factories showed that of the 3,591 persons employed, 65 per cent. were working under conditions exposing them to the fumes of phosphorus and the dangers of phosphorus poisoning. Here, as in many other industries, the ignorance or self-interest of many employers prevented them from properly instructing their workpeople concerning even the elementary and at best inadequate precautions against contracting this peculiarly loathsome disease.

The claim made by Dr. Ivy, dental examiner for the Pennsylvania Match Company, that under the present tariff and labor conditions, matches cannot be produced from sesquisulphid of phosphorus by manufacturers in this country in competition with foreign manufacturers[2] is absurd. Match manufacturers representing more than nine-tenths of the total output in America, in their desire to abolish "phossy jaw," have voluntarily gone on record in writing as follows:

---

[1] Proc. Fourth Annual Meeting, American Association for Labor Legislation.

> In the event of the prohibition of the manufacture of white phosphorus matches, we have no doubt of our ability to supply a strike-anywhere match which will be satisfactory.

It is interesting to recall that the treasurer of the match company which employs Mr. Ivy said in a letter to the U. S. Bureau of Labor (Bulletin 86, p. 131):

> So far as we are concerned, one thing is sure, if there is any substitute for white phosphorus that would eliminate the danger, even if it would cost more money, and considerably more money, I know that our people will be only too glad to adopt it.

Attempted regulation has been abandoned in one country after another after a fair test, and absolute prohibition of the use of poisonous phosphorus in match-making is now recognized as the only sure remedy for this horrible and wholly unnecessary disease.

The report of the Illinois Commission on Occupational Diseases, already referred to, shows the existence of similar dangerous conditions. Twenty-eight trades were investigated, in all of which lead-poisoning may occur, and 578 individual cases of lead poisoning were secured from the records of physicians during the past three years. Physicians will understand that this number is a minimum, because records are not consistently kept by private practitioners, and only recorded cases are included.

A striking illustration of what stringent workshop regulation can do toward decreasing the amount of sickness in occupations is given by Dr. Alice Hamilton. The figures given in her report are further emphasized by the fact that in one place investigated by Dr. Hamilton, where only thirteen men are employed, fifty men are engaged in the course of the year to maintain the minimum staff force. Another place engages 300 men to maintain a force of fifty. Still another, with a payroll of from 450 to 600, loses from 20 to 40 per cent. of its workers every pay day. In all these cases, the men drop out as they become "leaded."

A preliminary investigation into mercurial poisoning in New York and New Jersey produced in three months a record of sixty cases in the hatting industry. In Great Britain, on the other hand, where every case is immediately reported, only ninety-four cases for all industries have occurred in twelve years.

With the exception of phosphorus, lead and mercury poisoning, little, if any, investigations of value have been made in this country into the vast question of industrial poisoning. That extensive investigation carried out by competent authorities is urgently needed can be seen from the following list of poisons that are in every-day use in our industries:

Alcohol, Amyl
Alcohol, Methyl
Ammonia
Aniline
Antimony
Arsenic
Arseniuretted hydrogen gas.
Benzol
Carbon dioxid
Carbon disulphid
Carbon monoxid
Chlorid of lime
Chlorin
Chromium
Dinitrobenzol

Formaldehyd
Hydrochloric acid
Hydrofluoric acid
Lead
Manganese
Mercury
Nitrobenzene
Nitrous gases
Phosphorus
Picric acid
Prussic acid
Pyridin
Sulphur chlorid
Sulphuretted hydrogen
Sulphurous acid

This list does not, of course, exhaust the conditions to be found in industry that are detrimental to health. Dr. Thomas Oliver treats the subject of occupational disease under five general heads: (1) diseases due to gases, vapors and high temperatures; (2) diseases due to conditions of atmospheric pressure; (3) diseases due to metallic poisons, dusts and fumes; (4) diseases due to organic or inorganic dust and heated atmospheres; (5) diseases due to fatigue.

When the wide range of factors affecting detrimentally the health of the workers of America is realized, together with the fact that practically no scientific measures are in operation for their relief, it becomes evident that the problem of industrial disease is one that calls for immediate investigation. The success of such an investigation, and the measures to be taken following it, depend very largely on the cooperation of the medical profession. Physicians can furnish the knowledge that enables the subject to be intelligently and scientifically handled, and on them must devolve the responsibility of reporting to appointed authorities all cases of sickness due to the patient's occupation.

To secure this necessary preliminary step, the American Association for Labor Legislation has introduced into the legislatures of the principal industrial states a uniform bill providing for the reporting of occupational diseases by physicians. The essential parts of this uniform measure are as follows:

> Every medical practitioner attending on or called in to visit a patient whom he believes to be suffering from poisoning from lead, phosphorus, arsenic or mercury or their compounds, or from anthrax, or from compressed-air illness, contracted as a result of the nature of the patient's employment, shall send to the Commissioner of Labor a notice stating the name and full postal address and place of employment of the patient and the disease from which, in the opinion of the medical practitioner, the patient is suffering.

It is, of course, recognized that a national investigation of occupational diseases is needed. A most valuable aid in this work would be a clinic for the study of industrial diseases, such as has been established recently at Milan, Italy. Such an institution would be valuable in affording ideal conditions for the study and prevention of occupational diseases, and in connection with a scientific system of recording, it would immeasurably increase the social service of physicians.

Metropolitan Tower.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Ninth Month—Third Weekly Meeting

Diseases of the Nervous System (Continued)

Chorea

Etiology: Age, sex, season. Relation to rheumatism. Overwork in school, anemia, ocular defects. Heredity. Exciting causes.

Symptoms: Onset of spasms, character, intensity. Course of spasm. Endocarditis. Mental condition. General condition. Duration.

Treatment: Hygiene, diet, control of patient. Medicinal treatment, arsenic, sodium salicylate, antipyrin, strychnin, etc.

Acute Meningitis

I. Cerebrospinal Meningitis

Symptoms: Clinically may be (a) hyperacute, (b) usual, (c) mild, (d) chronic in form. Onset, vomiting, convulsions, chill, pain, muscular rigidity. Eruptions on skin. Fever. Headache, pain in neck, hyperesthesia. Delirium, apathy, coma, muscular rigidity, opisthotonos. Kernig's sign. Eye and ear symptoms. Respiration, pulse. Blood-count. Course, duration and terminations.

Treatment: Medicinal treatment. Serum treatment, technic, results.

II. Simple Acute Meningitis

Etiology: Pneumococcus, streptococcus and staphylococcus, colon bacillus, etc. Secondary to acute infections.

Diagnosis: History of previous disease, onset of brain symptoms.

Medical Education and State Boards of Registration

COMING EXAMINATION

Georgia Eclectic: State Capitol, Atlanta, about April 20. Sec., Dr. C. W. Miller, 192 W. North Ave.

South Dakota January Report

Dr. F. W. Freyburg, Secretary of the South Dakota State Board of Medical Examiners, reports the written examination held at Aberdeen, Jan. 11-12, 1911. The number of subjects examined in was 15; total number of questions asked, 125; percentage required to pass, 75. The total number of candidates examined was 32, of whom 29 passed and 3 failed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Northwestern University Medical School,	(1899) 90.3; (1909)	84.7; (1910) 85.6.
American Coll. of Medicine and Surgery, Chicago..	(1907)	81
College of Physicians and Surgeons, Chicago,	(1908) 76.2; (1910)	83.6, 88.5.
Rush Medical College..............	(1895) 75.1; (1908)	87.7
Hahnemann Medical College and Hospital, Chicago.	(1901)	75
Drake University	(1902) 76; (1910)	81.8
State Univ. of Iowa, Coll. of Med...	(1902) 80.9; (1910)	82.1
Keokuk Medical College, Coll. of Phys. and Surg..	(1900)	80.6
University of Michigan, Dept. of Med. and Surg..	(1909)	87.7
University of Minnesota, College of Medicine,	(1908) 75.9; (1909)	80, 80.4; (1910) 82.9.
Ensworth Medical College......................	(1909)	79.4

University of Toronto, Ontario......	(1907) 81.2; (1908)	83.5

FAILED

College	Year Grad.	Per Cent.
Bennett Medical College......................	(1909)	66.1
Drake University	(1902)	73
Creighton Medical College....................	(1907)	71.9

The following questions were asked:

BACTERIOLOGY

1. What kind of bacteria are most commonly found in suppurative processes. (*b*) Describe them. 2. What are the three sub-divisions of the colon typhoid bacillus group. 3. What do you understand by (*a*) Phagocytes. (*b*) Blastomycetes. (*c*) Thermal Death Point. (*d*) Antiseptics. (*e*) Disinfectants. 4. Describe a diphtheric throat. How would you obtain a culture? 5. How would you dispose of the excreta of (*a*) typhoid patient. (*b*) tubercular patient.

REGULAR THERAPEUTIC AND PRACTICE

1. Describe three of most common intestinal worms and give treatment for one kind. 2. Describe and treat rickets. What is [illegible]us and scorbutus? 3. What are the contra-indications of [illegible]um viride? What is its therapeutic value? 4. How would [illegible] distinguish between autotoxemia and acute ptomaine poisoning? 5. Describe symptomatic difference between tetanus and strychnin poisoning. 6. Differentiate acute alcoholism, apoplexy and epilepsy. 7. What is arthritis deformans? Give diagnosis and prognosis. 8. Describe and treat hemicrania. 9. What are the differences in the physical signs of initial incompetency and functional systolic murmurs? 10. Define briefly: Aphasia, apoplexy, thermic fever, myalgia fever, parotitis, septicemia, pyemia, pachymeningitis.

MEDICAL JURISPRUDENCE

1. Give signs of death by drowning. 2. What are the duties of a coroner upon receiving notice that a dead person has been found in his jurisdiction? 3. State the method of procedure, in this state, to procure the commitment of a person to the hospital for the insane. 4. In making a microscopic examination of blood-stains, what characteristics would lead you to believe they were produced by human blood? 5. What conditions, from a legal standpoint, would justify the induction of premature delivery?

PHYSIOLOGY

1. What action has the gastric juice on the carbohydrates and fats? 2. Give the *composition*, reaction, and uses of blood. 3. Describe the red blood-corpuscles and give their best known and most important function. 4. Describe the fetal circulation. 5. Name the erectile tissues of the body, and explain their function. 6. What digestive changes take place in the (*a*) small intestines? (*b*) in the large intestines? 7. Describe the sphygmograph and state its use. 8. How do arteries, veins; and capillaries differ as to function and structure? 9. Define emulsification, and saponification, and give examples of each. 10. What is an (*a*) efferent nerve? (*b*) afferent nerve? Give illustrations of each.

ECLECTIC MATERIA MEDICA, THERAPEUTICS AND PRACTICE

1. Define the terms diaphoretic, narcotic, and poison, and give examples of each. 2. Name several of the best stimulants, and give dose of each. 3. Name some of the best intestinal antiseptics, and doses of same. 4. Give the specific indications for hydrochloric acid, sodium bicarbonate, belladonna, aconite, and dose of each. 5. Diagnose and treat a case of pneumonia. 6. Give differential diagnosis between appendicitis, and gall-stones. 7. What do you know about infantile paralysis—its cause, symptoms and treatment? 8. What are the earliest symptoms of poisoning from the external use of carbolic acid. 9. Give symptoms and treatment of perforation of bowels resulting from typhoid fever. 10. Write a prescription for a good general tonic.

CHEMISTRY

1. Give a test for sugar in urine. 2. Give a common name for the following formula: H_2O_2, C H C_{13}, CH_4O, C_2H_5OH. 3. In what different compounds is sulphur found in nature? 4. What decompositions occur in the preparation of chlorin from rock salt? 5. Give chemical name and formula for lunar caustic.

EYE, EAR, NOSE AND THROAT

1. Diagnose and treat case of iritis. (*b*) Diagnose and treat case of keratitis. 2. Name and describe four errors of refraction and treat each. If lens is prescribed be definite. 3. Give treatment and prognosis of severe burn of eye involving lid and ocular conjuctiva. 4. Give treatment in well marked case of hypopyon. 5. Differentiate between diphtheria and follicular tonsillitis and treat case of follicular tonsillitis. 6. Diagnose and treat a case of hypertrophy of pharyngeal tonsil. 7. Describe the Eustachian tube, giving anatomy and function. 8. Draw diagram illustrating cross section of nose showing turbinated bodies, and treat a case of hypertrophy of inferior turbinate. 9. Give etiology, symptoms and treatment of empyema of frontal sinus. 10. Give three common causes of deafness and treat a given case.

OBSTETRICS

1. How would you treat vomiting of pregnancy? Give etiology. 2. Tell what you know about toxemia of pregnancy. 3. Diagnose and treat a case of placenta prævia, being called after mother is in labor. 4. Make an accurate diagnosis of a vertex presentation. 5. Give three main rules for the treatment of uterine inertia in labor. 6. Give immediate diagnosis and treatment of lacerations of perineum after labor. 7. How and when would you be justified to induce labor? 8. Describe the application of forceps. 9. What is a cystic mole? Give cause for its formation. 10. When would you use chloroform in labor?

ANATOMY, HISTOLOGY AND EMBRYOLOGY

1. Give a histological description of a hepatic lobule. 2. What is the embryonic origin of (*a*) the kidney, (*b*) the lungs, (*c*) the eyeball. 3. Describe the pancreas. 4. Give histological description of pulmonic alveoli. 5. What displacement occurs in a fracture of the femur at the junction of the middle and lower thirds? Why? 6. Describe the ankle joint. 7. Describe the *diaphragm*. 8. Describe the small intestine. 9. Name the muscles of respiration. Give origin and insertion of any two. 10. Name the abdominal viscera that are (*a*) completely, (*b*) partly, (*c*) without peritoneal investment.

SKIN AND GENITO-URINARY

1. Give symptoms, diagnosis and treatment of a beginning erysipelas of the scalp in an infant one year old. 2. Diagnosis and treatment of erythema multiforme. 3. Diagnosis and treatment of lupus vulgaris. 4. Diagnosis and treatment of perniones. 5. Etiology, diagnosis and treatment of acne vulgaris.

PATHOLOGY

1. What are lymphocytes, poikilocytes, blood-plates? 2. Give the blood changes in myelogenous leukemia. 3. What conditions are induced by (*a*) atrophy and (*b*) hypertrophy of the thyroid? 4. Give the pathology of cancrum oris. 5. Differentiate septic intoxication and bacteremia. 6. What are local infections? 7. Describe the intestinal lesion of typhoid. 8. What is an antitoxin? 9. The pathology of psoas abscess. 10. Define immunity.

DISEASES OF WOMEN

1. Give causes and treatment of pruritus vulvae. 2. Differentiate appendicitis and ovaritis. 3. Etiology, diagnosis and treatment of pyosalpinx. 4. What are the indications *for* hysterectomy? Describe one operation. 5. Give in detail your treatment for complete rupture of the perineal body with accompanying rectocele and procidentia uteri, in a woman past the menopause.

HOMEOPATHIC THERAPEUTICS AND PRACTICE

1. Outline your treatment of typhoid. 2. Name two of the most frequent complications of scarlet fever, with treatment of either one. 3. Give the indications for two remedies *useful* in the treatment of chorea. 4. Etiology, diagnosis and treatment of Bell's paralysis. 5. What symptoms would lead you to prescribe arsenicum, rhus toxicodendron, and sulphur in skin diseases. 6. Give symptoms, diagnosis and treatment of broncho-pneumonia. 7. Differentiate digitalis and aconite in heart disease. 8. Indications for two remedies in acute gastritis. 9. How would you *treat* hypostatic congestion of the lungs. 10. Outline your treatment of infantile convulsions.

HYGIENE AND SANITARY SCIENCE

1. Give in detail the method you would use as health officer in controlling diphtheria epidemic. 2. Is infantile paralysis infectious? If so, give rules for protecting the community. 3. Give incubation period of (*a*) scarlet fever, (*b*) diphtheria, (*c*) variola, (*d*) measles. 4. Give hygiene *and general* care of the patient to prevent infection of attendants and others in close contact with patient suffering from pulmonary tuberculosis. 5. Give general directions for the care of public schools, and care and inspection of school children.

SURGERY

1. Give diagnosis and treatment of strangulated inguinal hernia. 2. Diagnose and give treatment for cholelithiasis. 3. Diagnose and treat simple fracture of clavicle. 4. Diagnose and treat fracture of femur at the junction of upper and middle thirds. 5. How would you manage case of fecal fistula following appendiceal abscess? 6. Give diagnosis and treatment of hemorrhoids. 7. Given severe crushing injury of leg with shock—give treatment in detail. 8. Give diagnosis of and *treatment* for postoperative ileus. 9. Give diagnosis and treatment of carbuncle. 10. Give diagnosis and treatment of acute suppurative appendicitis; in case you operate, what incision would you make, and why?

Book Notices

THE PROCEEDINGS OF THE CHARAKA CLUB. Vol. III. Cloth. Price, $3 net. Pp. 174, with illustrations. New York: William Wood & Co., 1910.

In this volume of the "Proceedings of the Charaka Club," of twenty-one papers whose titles are given as having been read since the publication of the second volume, twelve are printed with many rare and interesting illustrations.

Dr. Dana contributes a study of the canticles of old anatomists called "When Apollo Strikes the Lyre," which recalls the days when the scientific world united in the familiar medium of the Latin tongue to celebrate the glories of their contemporaries in verse. When a distinguished professor died or had a festal day his admiring friends and pupils sent him verses from all parts of Europe. Even the works of the great anatomists were celebrated with song. A certain John Antoninus wrote a *carmen* addressed to the ghosts of the gentlemen whose remains had been dissected by Fabricius of Aquapendente, congratulating them on their good fortune in having been dissected by such a master of the art, and assuring them that the repose of their souls had been attended to. Spigelius had a whole *funiculus* of songs contributed to encourage him in his work. Antonio Scarpa, professor in Padua, received the tribute of twenty-five Latin verses written by his pupils and friends. Through three centuries these curious songs were the fashion; even Harvey, Sydenham and Radcliffe in England were celebrated in memorial verses. While the poems do not take high rank as works of art, still they have a great deal higher literary value than the conventional "resolutions" passed by moderns to signify respect for a distinguished departed brother. The custom has passed away, because, as Dr. Dana says, "the learned world has dropped its Latin without having picked up Esperanto;" and, while not maintaining that the formal praise adds anything to the real achievements of the profession, he hints, nevertheless, that physicians might have a better scientific imagination if they were to indulge their sensibilities a little, and not be so technical that they cannot enjoy the esthetic side of life.

Dr. Pearce Bailey makes a delightfully logical diagnosis of what has been known as Flaubert's epilepsy. From the manner in which Flaubert, as well as his friends, describes himself, and from what the novelist records of his peculiar psychology in the romance of "Madame Bovary," Dr. Bailey concludes that the famous fits were not epileptic, but convulsive attacks following emotional crises. Flaubert's physicians left no records of his case. They evidently did not understand it. Some bled him, one threw up his hands and prescribed quinin, another told him to stop smoking, and still another—Hardy, the dermatologist, we understand—called him a hysterical old woman to his face. This is the literary post mortem which Dr. Bailey, more sympathetically, sets forth.

In a paper by Dr. Smith Ely Jelliffe there appears a copy of the first illustration of the fissure of Sylvius, as presented by Franciscus Sylvius in the seventeenth century. So vague were ideas about the work of this remarkable anatomist that the honor of the name of the fissure had often been attributed to Jacobus Sylvius, who lived two centuries earlier. Study of the references makes it possible to trace the picture of a well-descended and highly endowed youth, who studied in Parisian, German and Dutch universities, till at the mature age of 23 he was crowned with laurels, received his cap, ring and book, and was sent forth with a kiss of peace to be one of the most distinguished lecturers and popular physicians of his day. It was said of him that when at 27 he went to Amsterdam the inhabitants acted as though Apollo had descended from Olympus to cure them.

No one reading Dr. Arpad G. Gerster's charming sketch of "Surgical Manners and Customs in the Time of Henry de Mondeville," can fail to appreciate the stages through which surgery has struggled from the middle ages, when it was considered a degrading manual trade, to the present day of luxurious nicety. It is interesting to find this clever old French fourteenth-century bachelor with a big practice grumbling thus: "Sometimes in a whole day I cannot manage to write a single line, being obliged to attend to my lectures, and having in addition to run hither and thither the whole day long to earn my bread, because I must earn everything I need, for myself and my household, by my own work."

De Mondeville's quaint, piquant Latin abounds with caustic humor, and shows deep insight into the devious ways and the cunning of charlatans and tricksters, who "though ignorant, thrive and are magnificently exalted by their practice, while the well-instructed, truth-telling and expert are oppressed, and frequently have to live the life of paupers and mendicants." So little change has there been in human nature, Dr. Gerster says, that "in one of his treatises we find the tricks of the present-day Christian Science beautifully delineated;" and truly, to read the arguments of the monks, concerning the divine nature of health, which de Mondeville satirizes, gives us a feeling that the benighted superstition of the middle ages is flourishing to-day.

To possess this little volume is to loiter at will with the medical great of forgotten ages, or to share the keenly humorous view of the writers of the papers concerning modern situations in medicine.

TEXT-BOOK OF NERVOUS DISEASES FOR PHYSICIANS AND STUDENTS. By Prof. H. Oppenheim of Berlin. Fifth Edition. Authorized Translation by Alexander Bruce, M.D., Physician to the Royal Infirmary, Edinburgh. Volumes I and II. Cloth. Price, 2 guineas. Pp. 1424, with 432 illustrations. Edinburgh: Otto Schulze & Co., 20 S. Frederick St., 1911.

To commend the work of Oppenheim seems like approving a Rembrandt or complimenting a Newton. For years this text-book has been by far the best one in any language. To review it is to recite a catalogue of excellencies. English readers unfamiliar with German are therefore deeply indebted to Dr. Bruce and his Scotch publisher.

The first volume, 602 pages, embraces two parts: a general part (92 pages) and a special part (510 pages). The first, on mode of examination and general symptomatology, contains a wonderful fund of information remarkably well condensed. The second covers diseases of the spinal cord and peripheral nerves, including 147 pages on anatomy and physiology of the cord, localization in the spinal cord (eleven most valuable pages), vessels, etc.

The second volume (819 pages) is devoted to diseases of the brain, the neuroses, diseases of the sympathetic, angioneuroses and conditions of intoxication in which the nervous system is affected. This includes sixty-six pages on the anatomy and physiology of the brain and seventy-two pages on the general symptomatology of brain diseases.

The entire work is a storehouse of thoroughly digested information. The author long has been a contributor to almost every department of the science of neurology and the art of the neurologist. His erudition, keen discernment and practical balance are apparent in the work before us. Every chapter—yes, every page—bears the stamp of the author's keen scrutiny. The field of nervous diseases is covered more completely than by any other treatise on the subject. Affections in which surgical therapy is of importance seem to be particularly well handled. We might instance tumors of the brain and of the cord, dislocation and fracture of the spinal column and the late stages of poliomyelitis.

In many of the better works on diseases of the nervous system the neuroses receive rather scant or, at least, inadequate attention. One might expect this in a German product, but the expectation is not fulfilled in this work. Functional nervous diseases receive consideration satisfactorily full and particularly sane. We especially commend the sections on conditions of anxiety and imperative ideas.

Perhaps it is unnecessary to note that, while the large subjects in neurology receive the most comprehensive treatment, the lesser ones are not neglected. Indeed, often it is these lesser maladies or symptoms which loom large to the patient and to the practitioner who is unfamiliar with them and who fails to find them on a hurried hunt through his library. For instance, erythromelalgia, cephalic, hydrophobic, paralytic and bulbar tetanus, facial hemiatrophy, pachyacria, astasia-abasia, akinesia algera, glossodynia and the cerebral softening of gas poisoning might easily elude the practitioner who has no work like this on his shelves. We approve, too, the introduction of a chapter on general paresis.

The author's extensive and catholic knowledge of the literature is also worthy of note. Americans often have just cause of complaint against their European colleagues, because the latter incline to neglect or underestimate the value of American work; but such complaint cannot be lodged against Oppenheim. A few minutes' glance sufficed to find twenty American names. Indeed, scarcely a neurologist of note in this country has failed of mention in this work. Writers of other countries have received like attention, credit and courtesy.

While the book is satisfying in almost every respect, possibly a more extensive and minutely classified index would have made it more easily useful to some readers. The index, however, is unusually good for a German publication.

In conclusion, we have to record our sincere pleasure in a translation which is a real interpretation: neither a labored effort to transplant foreign idioms bodily, nor a fluent composition lacking in precision. We miss alike the routine phraseology of the hack and the absurd inaccuracies of the technically ignorant. When we say that the translation is fully worthy of the original, we consider that we have rendered full measure of commendation. The numerous illustrations are extremely well done; in some instances better than in the original.

A TEXT-BOOK ON DISEASE-PRODUCING MICROORGANISMS. Especially Intended for the Use of Veterinary Students and Practitioners. By Maximilian Herzog, M.D., Professor of Pathology and Bacteriology in the Chicago Veterinary College. Cloth. Price, $4.75 net. Pp. 644, with 238 illustrations. Philadelphia: Lea & Febiger, 1910.

This book, according to the title, treats of disease-producing microorganisms, and is especially intended for the use of veterinary students and practitioners. According to the material discussed, it seems to be intended for veterinarians, physicians, bacteriologists, pathologists, dairy students, etc. This multiplicity of subjects is a serious drawback, in our opinion, and the book would be more useful if the author had confined himself to the subject of veterinary bacteriology. This part is comprehensive and instructive.

Unfortunately, many errors and misstatements have found their way into the text. Some typographical errors and misspelled proper names have been overlooked. The composition is often not quite clear, and occasional contradictions exist. A few of the erroneous statements are these: The author says that invertase splits saccharose into dextrose. The fact is, however, that dextrose and levulose are the splitting products. Two quarts should read "nearly equal to 2,000 c.c." rather than "1,000 c.c."; and *B. diphtheriæ* is stated to produce gas in the presence of glucose—a serious error.

The chapter on the preparation of culture media is not quite up to date. Agar-agar can be filtered readily within a few hours by using folded filters made of good filter-paper; the author, however, says that it takes several days. It is stated that gelatin must be sterilized in the Arnold; but in modern laboratories the autoclave is used with good success. The clarifying process by the use of egg-albumin is entirely omitted. The author uses litmus as indicator for titrating media; phenolphthalein is more accurate and more modern.

The subject of immunity is not clearly elucidated, especially the part dealing with Ehrlich's side-chain theory, and the description of preparing and testing diphtheria antitoxin is not correct. In the chapter on milk the lactic acid bacteria are hopelessly confused and the term is not used in the usually accepted sense. In discussing the thermal deathpoint of tubercle bacilli in milk, the author does not seem to consider the exact work of Theobald Smith, Rosenau, and Russell and Hastings worthy of mention. The objections enumerated against the pasteurization of milk are erroneous without exception, and the author utterly ignores the most up-to-date work on this subject. The statement that Rochester, N. Y., has experienced a deterioration of its milk-supply through pasteurization seems contradictory to an utterance of the health officer of Rochester, Dr. Goler, that there never was an appreciable amount of pasteurized milk in that city.

Animal diseases and the parasites causing them are treated well. In the preface it is stated that there is no text on veterinary bacteriology in the English language. If this book had been devoted to this subject *exclusively*, therefore, it would undoubtedly have been an unqualified success.

THE RACIAL ANATOMY OF THE PHILIPPINE ISLANDERS. Introducing New Methods of Anthropology and Showing Their Application to the Filipinos with a Classification of Human Ears and a Scheme for the Heredity of Anatomical Characters in Man. By Robert Bennett Bean, M.D., Associate Professor of Anatomy, Tulane University of Louisiana, New Orleans. Cloth. Price, $2 net. Pp. 236, with 26 illustrations. Philadelphia: J. B. Lippincott Co., 1910.

This book is a compilation, with modifications, of a series of articles published in the *Philippine Journal of Science* on the racial anatomy of the different peoples of the Philippine Islands. The author has studied the living form rather than the skeleton as a method of segregating the different types, of which he defines seven, into which all the peoples of the island may be classified anthropologically. The three principal types are the Primitive, which represents most nearly the original or the oriental type; the Iberian, which conforms to a type representing the admixture with Spanish blood, and the Australoid, representing the primary negroid element. The others are not so important, and represent various blends and mixtures of the three principal types. The studies of Filipinos from all parts of the Archipelago show that probably a third of the population is Iberian, owing to Spanish interbreeding over a period of several hundred years. These are more susceptible to tuberculosis, which is quite prevalent among them, whereas the original Filipinos, or the Primitive type, are comparatively free from this disease. The author believes that the Iberian will ultimately disappear, leaving new combinations and blends unlike the original types. The Chinese and Japanese have left their impress on the types, as have also the Indians, whom the author says, no doubt swarmed over the Philippines for many more centuries than did the Spanish. In pursuing his studies and establishing the types the author has made hundreds of observations and measurements of Filipinos, both those in the schools and the natives in the country. He has laid especial emphasis on shape of head, character of nose, teeth and ear, comparative length of limb, character of skin, hair, etc., and position of the umbilicus, which latter the author presents as a point of significance in anthropologic study. The book contains many photographs of Filipino types and the author draws many interesting conclusions as to the place of origin and distribution of the different races of mankind. The work is an interesting contribution to anthropology.

THE AMERICAN YEAR-BOOK. A Record of Events and Progress, 1910. Edited by S. N. D. North, LL.D., Under Direction of a Supervisory Board Representing National Learned Societies. Cloth. Pp. 867. New York: D. Appleton & Co., 1911.

This volume is the first of a projected series of annual publications intended to fill a place distinct from others already in the field. Statistical matter is not given so abundantly, but the attempt is made to give something like a survey of general progress in the lines of "Comparative Statistics," "History and Law," "Government and Administration," "Functions of Government," "Economic and Social Questions," "Industries and Occupations," "Science and Engineering," "The Humanities," and "Current Record." Arrangement is topical, with cross-references and an analytical index. The work seems to be well done in the main, much of the information being presented in a more interesting and available form than is usual in such works of reference.

So far as preliminary examination shows, the only decidedly disappointing feature is the subdivision of "Literature and Language" under "The Humanities." Considering the fact that almost no attempt is made to give the most notable original works of the year in any language, or in any department of pure literature, the general reader will probably grudge the space given to language text-books, and wonder that it has been thought necessary to mention translations into English of foreign works possessing neither timely interest nor transcendent importance.

In the section on medicine and hygiene, covering twenty pages, Alexander Lambert briefly reviews the progress in medicine, surgery, public health, medical education, nursing, vital statistics, etc., and gives a list of the important medical books published during the year. Most attention is given to tuberculosis, poliomyelitis and others of the infectious diseases, the important discoveries and developments in research and the provisions made by endowment for the promotion of these. Among the many things worthy of mention the author, with judgment and discrimination, has selected those most important and of largest bearing, and has editorially commented on them in an interesting way. The article fairly reflects the status of those subjects at the end of the year.

The Diseases of China, Including Formosa and Korea. By W. Hamilton Jefferys, M.D., Univ. of Pennsylvania, Medical Missionary in China, and James L. Maxwell, M.D., London, Medical Missionary in Formosa. Cloth. Price, $6 net. Pp. 716, with 360 illustrations. Philadelphia: P. Blakiston's Son & Co., 1910.

This book will be of value to medical missionaries or practitioners wishing to take up the practice of medicine in China. It does not purport to be a complete text-book on the diseases of the East, but reviews and compares interestingly the prevalence of many of the world-wide epidemic diseases, as plague, cholera, malaria, tuberculosis, syphilis and gonorrhea. The differences in the requirements of practice in China as compared with Western countries are pointed out, and the authors draw from their long experience in their presentation of the subjects. The greater prevalence of tuberculosis is noted, the opium habit is interestingly discussed, hospitals throughout China and Formosa, their equipment, and their work, are pictured and described, and the needs of the country in a medical way are set forth. The affections peculiar to the country, and unusual forms of more or less familiar diseases or lesions, as of elephantiasis, various tumors, syphilis and skin affections, and also of gynecologic and other surgical affections, due largely to neglect of proper treatment, are described. Metazoan and protozoan diseases are given considerable space.

Perhaps the most valuable suggestion in the book is as to the immense field offered for research and comparison of diseases occurring in new environment and among peoples with different habits, diet, etc. The experience of the authors as described in this book will undoubtedly be drawn on in future studies of many diseases.

An Anatomical and Surgical Study of Fractures of the Lower End of the Humerus. By Astley Paston Cooper Ashhurst, M.D., Prosector of Applied Anatomy in the University of Pennsylvania. The Samuel D. Gross Prize Essay of the Philadelphia Academy of Surgery, 1910. Cloth. Price, $2.75 net. Pp. 163, with 150 illustrations. Philadelphia: Lea & Febiger, 1910.

The subject-matter of this little volume is divided into two parts; the first deals with the anatomy, mechanism, complication and treatment of these fractures, and the second contains the clinical histories in detail of the fifty-six cases which form the basis of this study. The first part shows that the author has done a great deal of original work and has devoted much time and study to the elucidation of the pathogenesis of these fractures.

The method of making a proper examination of the elbow for diagnostic purposes and the method of interpreting skiagraphs of this region are very lucidly explained. The author earnestly advocates the hyperflexed position in the treatment of most of the varieties of fracture involving the lower end of the humerus, and his arguments in favor of this position are quite convincing, provided one remembers the most important rule in this connection, which is not to maintain the arm in any position without change sufficiently long to permit of fixation of the point in that position.

Fractures of the elbow are so common in children and the results following are so frequently not what they should be, that a careful study of this little volume is earnestly recommended to all who treat these conditions.

Lessons on the Eye. For the Use of Undergraduate Students. By Frank L. Henderson, M.D., ex-President of the St. Louis Medical Society (1905). Fourth Edition. Cloth. Price, $1.50 net. Pp. 238, with 138 illustrations. Philadelphia: P. Blakiston's Son & Co., 1910.

This little book, after briefly taking up the anatomy of the eye and the surrounding structures explains in an elementary way the physics of light, of prisms, lenses, etc.; it explains refraction and the various errors of refraction, describes disorders of the ocular movements, and discusses the diseases of the different structures of the eye, and their treatment. The author states that the book is intended as a substitute for the students' class-room notes, and it serves that purpose very well. The book is well illustrated, and should prove an aid to the medical student.

Collected Papers by the Staff of St. Mary's Hospital, Mayo Clinic, Rochester, Minn., 1905-1909. Cloth. Price, $5.50 net. Pp. 668, with 228 illustrations. Philadelphia: W. B. Saunders Co., 1911.

This collection of the papers of Drs. William J. and Charles H. Mayo and the other members of the staff of St. Mary's Hospital, previously published elsewhere, brings into compact form in one volume a mass of material on surgical subjects, and investigations of the pathology of surgical diseases treated in that hospital from 1905 to 1909. It is indexed as to authors and subjects, and affords a convenient source of reference to those wishing to look up what has been done at St. Mary's.

Medicolegal

When Expert Witnesses are Entitled to Special Compensation

The Supreme Judicial Court of Maine holds, in the consolidated cases of Gordon, O'Neil and Twitchel vs. Conley (78 Atl. R. 365), that, under certain circumstances, expert witnesses are entitled to reasonably special compensation. Here the plaintiffs were employed by the defendant or her attorneys to make an examination of her physical condition for the purpose of enabling them to qualify as medical expert witnesses for her in a personal injury case she had against a railway company. They were not summoned, but appeared voluntarily at the request of counsel, without any agreement as to their compensation, and by special request remained in court three days to listen to the experts on the other side, and testify in rebuttal, if necessary. The defendant contended that they were entitled to only the statutory compensation of ordinary witnesses.

It will be observed, the court says, that the question raised was not whether an expert witness can be summoned into court in the regular way, and be required to give in evidence all the knowledge he may have acquired as an expert on a particular subject under investigation, for the regular witness fee, but whether, having been employed by a party to give special attention to the investigation of a matter out of court, and then to appear in court, not only to testify as an expert witness, but to remain in court for a specific length of time with loss of regular occupation, not by order of the court, but by request of the party employing, a witness is entitled to receive reasonable compensation beyond the regular witness fee for such services. If a party saw fit to summon an expert witness to testify in court without any knowledge as to what he might say, whether the witness would be required for the usual fee to give all the expert knowledge he might have on the subject under investigation did not arise here. That was not the case before the court.

A witness under subpena after testifying for an hour or half an hour might be excused by the court and enabled to pursue his ordinary occupation, instead of losing three days. He is under no contractual obligation whatever to the party calling him. He cannot even be unwillingly interviewed before testifying. He takes the stand, testifies, and leaves it. That is all he is required by law to do. The court, of course, could require him to remain in attendance, but it is an unusual case in which an expert witness, capable of earning perhaps $100 a day, would be required to remain at $1.50 per day for the benefit of private interests. Hence it appears that a witness summoned into court, and for non-appearance subject to contempt, stands in an entirely different relation to the court and the parties from the witness who appears in court without summons, but on a special agreement not only to prepare and testify, but to remain in court for the special benefit of the party calling him. Such a witness performs services outside the statutory requirement, and is entitled to whatever his services are reasonably worth above the legal fee due ordinary witnesses. The plaintiffs rendered bills for $50 per day, but the jury allowed them $37.50 per day, which, in view of their reputation and skill, is deemed entirely reasonable.

Requisites for Holding Brothers and Others for Bills—Inadmissible Evidence

The Supreme Court of Rhode Island holds, in Churchill vs. Hebden (78 Atl. R. 337), that, the evidence failing to prove either an express or implied promise of the defendant to pay for an operation for appendicitis performed on his brother, a verdict was properly directed in the defendant's favor. It appeared that the patient was a man 29 or 30 years of age, who lived with wife and children in one city, while his brother, the defendant, was a resident of another city. The family physician testified that he telephoned to the surgeon who performed the operation, and made arrangements for it, but did not remember that any thing was said about the fees or who should pay them. The patient testified to having objected to having the operation performed and having asked the family physician about the cost, stating that he was the one who would have the bill to pay, and being told not to mind about the bill, it being a little matter that could be fixed up afterwards. The surgeon who performed the operation died before the trial of the case, which was revived in the name of his executrix, so that his testimony was lacking. There was, however, no denial that the operation was performed, or that the charge for it was $500, but only as to this defendant's ability—a denial that he had agreed to be responsible for the payment for the operation.

With the sole question thus being whether the defendant had employed the surgeon, or had agreed to pay for his services rendered to his brother, a question for the jury to pass on, the court holds that there was no error in refusing to admit in evidence the surgeon's books of account. The burden of proof was on the plaintiff to satisfy the jury by a fair preponderance of the evidence of the employment of the surgeon by the defendant. To show the entry on the books would merely show the deduction reached by the surgeon through his sources of information as to the circumstances surrounding the transaction. Those circumstances were to be submitted to the jury, who were entitled to consider them without knowledge of the inferences drawn therefrom by either party to the transaction. The parties necessarily took an interested view of the situation. The jury should consider the same without prejudice.

Nor was there error in excluding evidence as to other contracts or payments made by the defendant, as, for example, who paid the nurse for her services, or whether the defendant engaged or paid the hospital wherein the operation was performed.

There being no testimony of an express promise to pay, the jury were correctly instructed that, if the plaintiff was entitled to recover in this case, it must be by virtue of certain circumstances by which the law would imply a promise on his part to pay for the services. For instance, if a husband calls a physician to attend his wife, being under obligation to take care of his wife, the law would imply a promise to pay for those services, even though he made no promise. If a father calls a physician to attend his minor son, he being under obligation to take care of that minor son, the law would imply a promise to pay for those services. But where a mere stranger —and brothers are strangers in that respect—where a mere stranger calls on a physician to attend a third person, whom the one calling the physician is under no obligation to take care of, then the law will not imply any promise to pay for the services rendered to the third person.

Powers of Courts on Appeals from Board Decisions Refusing Licenses

The Supreme Court of Washington, In re Littlefield (112 Pac. R. 234), determines the powers, under the 1909 statutes of that state, of the courts on appeals from decisions of the State Board of Medical Examiners refusing licenses to practice medicine and surgery, and affirms a judgment directing the board to issue the license applied for in that case.

The record, the court says, showed that the license was refused by the board principally for the reason that the applicant did not obtain a rating equal to 60 per cent. on the subjects of histology, pathology and general diagnosis, which he was required to obtain under the statute before a license could issue to him. The first contention on the part of the board was that the court had no jurisdiction to hear this case; that it could not administer the provisions of the medical act as applied to appeals from orders of the board denying a license after examination, because, it was asserted, it is familiar law that, if the court cannot administer the law on a subject brought before it by virtue of the appellate statute, the court has no jurisdiction, to sustain which announcement of the law many cases were cited. But this was assuming the very question at issue. It seems to the Supreme Court that under the statute the court has the right to administer the provisions of the medical act, for the statute specially provides for an appeal from the decisions of the board. Section 13 of the act provides that, "In any case of the refusal or revocation of a license by the said board under the provisions of this act, the applicant whose application shall be so refused, and the licentiate whose license shall be so revoked by said board, shall have the right to appeal from the decision so refusing or revoking such license within thirty days after the filing of such decision * * * to the superior court," etc. And provision is made for an appeal from the decision of the Superior Court to the Supreme Court.

It was contended that, if this statute was to be given force at all, it must be construed to the effect that the appeal is not from the facts in the case or the merits of the case, so far as the examination is concerned, but only for the purpose of having determined any questions of law arising on the examination or in connection with the same. But the statute is a general one, and confers the general right without any limitation of this kind. So far as the statute itself is concerned, it does not remove from the operation of the appeal questions of fact, any more than it does questions of law.

But it was insisted that it must be construed with reference to the asserted fact that it would be a travesty for the superior court to undertake to pass on the qualifications of applicants to practice medicine; that it would resolve itself simply into the hearing of expert testimony on questions brought before the court. Difficulties of this kind are presented in the trials of many cases. A common instance is where a defense is based on the alleged insanity of a defendant in a criminal action. The testimony of alienists and other scientists is the controlling testimony in the case. The legislature evidently was not willing to leave the exclusive and final determination of this question to the discretion of the examining board, but evidently thought that justice and public policy demanded that there should be a review of the action of this tribunal.

It is true, there are some inconsistencies in the act; one of which is the fact mentioned by the board, that there may be an oral examination which it would not be possible to transmit in the record. But that it was intended by the legislature that the evidence generally should be transmitted to the Superior Court is evident from the provisions of the statute, for the law requires that the secretary shall within ten days after the service of such notice of appeal, transmit to the clerk of the Superior Court to which such appeal is taken, a certified copy, under the seal of said board, of the decision of said board, and the grounds thereof in the case of the refusal of the license; that the clerk of the court shall docket such appeal cases, and that they shall stand for trial in all respects as ordinary civil actions, and like proceedings be had thereon. It also provides that on said appeals said causes shall be tried *de novo* (anew), which excludes the idea advanced that only questions of law shall be passed on by the Superior Court. It provides that the examination papers shall form a part of the records of the board, and shall be kept on file by the secretary for a period of one year after each examination. All these and other provisions of the statute tend to show that the preservation of such records is in the interest of appeal.

Again, it was contended that, if the statute is to be literally construed, the proper procedure was not followed in this case, for the court only passed on the question in the main as to whether the applicant had been properly rated in his examination on the subjects of histology, pathology and general diagnosis, while the other subjects on which he was examined were not examined by the Superior Court; that a trial *de novo* is a trial anew, and that a trial anew means a trial of all questions that were involved in the case below. But it seems to the Supreme Court that this is not a broad view of this statute. Undoubtedly a trial *de novo* does mean, and is generally understood to mean, a trial anew; but it means anew, of course, only as to the questions in issue. In this case, so far as the applicant was concerned, he was satisfied with the rating he received on the other subjects of examination, and there was no objection made to them by the board, so that they were really not in issue in the case, and the case was tried *de novo* (anew) so far as the issues were concerned. Finding no reversible error, the judgment directing the issuance of a license is affirmed.

MEDICAL SOCIETY OF THE MISSOURI VALLEY

Twenty-Third Semi-Annual Meeting, held at St. Joseph Mo., March 16-17, 1911

The President, Dr. Donald Macrae, Council Bluffs, Ia., in the Chair

The Present Status of Salvarsan

Dr. Alfred Schalek, Omaha: It is premature and risky to let a patient with syphilis go with one or only a few treatments with salvarsan. Syphilis is still a serious disease which requires prolonged and thorough attention. Salvarsan has not yet been proved to be greatly superior to mercury, and, while it acts more rapidly on small lesions and may be of benefit in cases in which mercury is powerless, only time can tell whether or not the results will be more permanent.

DISCUSSION

Dr. C. A. Good, St. Joseph, Mo.: Salvarsan quickly causes disappearance of the primary chancre and mucous patches, but it is doubtful whether or not it will drive the spirochetes completely from the body. Two or three interesting observations have been made of children with congenital syphilis who were given salvarsan and later died, and it was found that the organisms had practically disappeared from all the internal organs where usually they are found in abundance, with the exception of one instance, in which they were found in the lungs.

Dr. T. M. Hall, St. Joseph, Mo.: There has been a tendency to promise a syphilitic that one injection of salvarsan will practically cure him. This is unfortunate, because, if later the disease is not annihilated by one injection, the man is imbued with a false idea as to his true condition.

Dr. F. S. Mason, New York City: While salvarsan may not be so good as mercury, when it is used the acute symptoms are relieved quickly. A woman who had the acute lesions of syphilis and was attending to her business received injections of salvarsan and within a week practically all the lesions disappeared, so that she could not infect anyone else.

Difficulties Encountered in Late Operations for Intestinal Obstruction

Dr. Herman E. Pearse, Kansas City, Mo.: By the following procedures patients with late cases of intestinal obstruction can be saved: 1. Empty the bowel at first operation and allow time to recover from toxemia before resection is practiced unless gangrene should forbid (ten-minute operation). 2. Do this by employing the long intestinal tube and emptying the distended bowel as the first step after finding the obstruction; close the wound after providing escape. 3. By the use of the glass tube of Paul or the rubber tubes with depressed external grooves, as advised by Marro, the toxic fecal matter may be conveyed beyond the wound, thus securing primary union and safety from abscess. 4. The bowel edges may be brought out of the incision beyond the skin and the open treatment by a nurse and water washing may be substituted for the closed method of filthy gauze and pads of cotton. 5. A second and even third operation may be [illegible] to complete the work when the patient has recovered from effects of the obstruction and vomiting.

DISCUSSION

Dr. John E. Summers, Omaha: Sometimes in cases of strangulated hernia, when gangrene is present, one can establish an artificial anus by cutting into the gut and allowing this opening to remain until the circulation is reestablished; then an operation may be done later. If drainage is carried out, it is wise to wash out the gut through a tube.

Dr. C. Lester Hall, Kansas City, Mo.: I differ with Dr. Pearse in regard to making the incision. We can open the abdomen more widely and freely and reach parts of the abdominal cavity better through a median incision, and we have less trouble through that incision in the after-treatment, and we get better union there than in any other part of the abdominal wall.

Dr. O. Beverly Campbell, St. Joseph, Mo.: I agree with Dr. Pearse that a good place to make the incision is about the border of the right rectus, because there is more trouble in the right side in intestinal obstruction than anywhere else, and the fact that one wants to drain in the median line; therefore, I would favor incision at this place in most cases.

Dr. S. H. Smith, Omaha: In a case of intestinal obstruction in a woman, the obstruction was caused by three constricting bands around the sigmoid flexure. These bands were cut. There were adhesions around the cecum which were broken up. Three days after the operation, the patient had natural bowel movements without the use of purgatives, and she has not had to take any purgatives since.

Dr. F. H. Clark, El Reno, Okla.: Shock in abdominal operations comes more from rough handling of the intestines than from any other one thing that enters into surgical work in the class of cases under discussion. A prominent surgeon told me not long ago that he attributed his remarkable success to two things: first, he had acquired a technic which enabled him to get in and out of the abdomen in a very short time; and second, he had learned to handle the intestines just as gently as it was possible to do it.

Dr. John P. Lord, Omaha: When we have a gangrenous gut to deal with, I believe that it should be excised, then we have an open bowel and can drain. We should not pack it with gauze and cover it with rubber tissue. The Murphy button tempts one to make an immediate anastomosis, which would be the means of causing the patient to suffer from the toxemia that kills so many of these patients who have so-called secondary shock. I do not believe in secondary shock unless there is secondary hemorrhage. The tube is a good thing, but it tempts us to do too much in the very cases that require drainage without too much manipulation.

Dr. S. G. Zink, Leavenworth, Kan.: I have had three cases of fecal impaction, and I have found that by using a 25 per cent. solution of peroxid of hydrogen, and putting the patient in the knee-chest or in the exaggerated Sims position, with the head low down, one or two injections of 8 ounces, followed by irrigation, would break up these fecal masses.

Dr. C. H. Wallace, St. Joseph, Mo.: For the average surgeon, who sees these cases only occasionally, I am satisfied that the simpler method of drainage by the introduction of a large tube will result in a greater saving of life than more extensive work.

Dr. Jacob Geiger, St. Joseph, Mo.: Early and correct diagnosis is most important. It is easy for us to say what to do, but every case is a law unto itself, and when we have a case of acute intestinal obstruction and open the abdomen and feel the pathology, then we have to use our brains to determine what is best to do.

Dr. V. L. Treynor, Council Bluffs, Iowa: I believe that if efforts were directed toward a more certain and early diagnosis it would simplify the treatment of these cases very materially. I do not like to hear the internists criticized for so-called neglect when the surgeon himself is sometimes incapable of making a diagnosis when he is called early.

Dr. C. C. Conover, Kansas City, Mo.: Modern methods of diagnosis have improved so wonderfully in the last four or five years that most internists can make a diagnosis of intestinal obstruction, and need not wait and call in a surgeon to tell them what is the matter with the patient.

Dr. H. M. Clark, Platte City, Neb.: We as country practitioners call in surgeons and they operate on patients with intestinal obstruction and lose 40 or 50 per cent. of them; we can do nearly as well ourselves.

The Roentgen Ray in Postoperative Cases

Dr. R. D. Mason, Omaha, showed the value of the *x*-ray in cases in which operation has been done, and advised its use in all postoperative cases in which malignancy is suspected. He pointed out the fallacy of waiting until a return of the disease before beginning the use of the rays.

DISCUSSION

Dr. Alfred Schalek, Omaha: Every cancer operated on should have postoperative *x*-ray treatment.

Dr. John P. Lord, Omaha: I have an abiding faith in the therapeutic value of the *x*-ray in the treatment of cancer in selected cases in which it can be reasonably expected to do some good, and practically every case should receive the benefit of this postoperative treatment.

The Rôle of Tuberculin in the Diagnosis of Pulmonary Tuberculosis

Dr. Logan Clendening, Kansas City, Mo., reviewed the methods of early diagnosis of pulmonary tuberculosis and said: 1. In infants and children the v. Pirquet test is of great value and positive, the younger the child the higher its value; it is somewhat less valuable if negative. 2. In adults there is no method of using tuberculin for diagnostic purposes that has uniform value in all cases; the subcutaneous method is probably the best.

Colica Mucosa

Dr. J. M. Bell, St. Joseph, Mo.: My experience with this disease leads me to believe the enteroptotic habit, plus autointoxication and constipation, is the foundation on which the disease is based; the neurosis being secondary. When the digestive tract is restored, a normal state of equilibrium is obtained.

Local Anesthesia with Quinin and Urea Hydrochlorid

Dr. C. M. Nicholson, St. Louis: I am convinced by experience with thirty-two cases that quinin and urea hydrochlorid is destined to occupy a prominent position as a local anesthetic. The greater length of time required after the injection of the quinin and urea hydrochlorid before the anesthetic effect is fully manifest is its principal disadvantage.

DISCUSSION

Dr. John P. Lord, Omaha: I have given this anesthetic in as many cases as Dr. Nicholson has mentioned and can unqualifiedly endorse it. This winter I used it in resecting the ribs in cases of empyema, and it worked admirably.

Dr. J. P. Standley, Bedford, Iowa: I have repeatedly operated on hemorrhoids with this anesthetic with satisfactory results.

Dr. J. H. Dillon, Auburn, Neb.: I wish to speak highly of this anesthetic, although I have only used it in two or three cases. I have also seen satisfactory results with it in the hands of others.

Dr. E. H. Thrailkill, Kansas City, Mo.: I have used quinin and urea hydrochlorid with good results, but I prefer stronger solutions than are used by some practitioners. After operations on the rectum I have used this anesthetic to prevent postoperative pain.

Dr. R. C. Dorr, Batesville, Ark.: I do not believe that there is any major surgical work done with a local anesthetic without pain.

Dr. A. J. McKinnon, Lincoln, Neb.: I operated on a man for hemorrhoids, using this anesthetic, and after the operation the patient rode home in a buggy.

Suggestions for the Application of Lactic Ferments in Genito-Urinary Work

Dr. F. S. Mason, New York City: These ferments are useful in treatment of diseases or infections of the gastro-intestinal tract, since they inhibit the growth of the pathogenic organisms. Drs. Holbrook Curtis and Otto Glogau of New York have used suspensions of lactic ferments in bouillon successfully in treatment of suppurating discharges from sinuses and nasal passages, as well as from the ear.

Peritonization in Abdominal and, More Particularly, Pelvic Surgery

Dr. John E. Summers, Omaha: By peritonization or peritoneoplasty is meant the covering over by peritoneum of all tears, lacerations and losses of substance of the peritoneum due to surgical procedure. In some cases the peritoneum may be separated from the abdominal wall, commencing at the lower angle of the incision toward the space of Retzius, or at the sides, a great part of the bladder being likewise freed. These flaps are made large enough to cover over the posterior wall of the pelvis. In other cases, the technic consists in transporting the sigmoid flexure across the pelvis and suturing it in such a way that all raw surfaces are covered over. The sigmoid is only fixed below and is nearly always sufficiently mobile to be carried across the pelvis to the right side as far as the cecum. When the uterus is preserved, the sigmoid is sutured to the lateral walls of the excavation and across the fundus of the uterus. When the uterus is sacrificed, the sigmoid is sutured to the lateral walls of the excavation and to the bladder. Drainage should be made through the vagina. Amann emphasizes the fact that this technic is particularly advantageous when septic pus or genital abscesses communicate with the intestine—for example, a pyosalpinx, or a suppurating tumor of the ovary, opening into the large bowel; and also when genital abscess coexists with perforative appendicitis. The intestinal sutures are situated under the protection of the cavity drained and are extraperitoneal. Two vital principles are involved in peritoneal autoplastic surgery: first, the more vital principle, the prevention of infection; second, the prevention of postoperative intestinal obstruction.

Care of the Hypertrophied Prostate

DR. F. H. CLARK, El Reno, Okla.: The responsibility for early diagnosis and advice must, of necessity, rest with the family physician. While this condition usually comes on with advanced age, it may occur even in childhood. Operative procedure is the only treatment that offers hope for permanent cure and a comfortable life after operation. The operation which presents the lowest mortality is through the lower perineal route. We should never forget that 10 per cent. of these hypertrophied prostates become malignant if allowed to go on, and that our only hope of avoiding that is an early operation. We must not forget that we should continue to use sounds on these patients following operation until we are certain that there will be no contraction of the scar formed that may serve as an impediment to the free flow of urine.

Frick, Kansas City, Mo.; "Treatment of Tuberculosis," by Dr. G. N. Ryan, Des Moines, Iowa; "Acute Anterior Poliomyelitis," by Dr. L. A. Skoog, Kansas City, Mo.

CLEVELAND ACADEMY OF MEDICINE

Regular Meeting, held March 17, 1911

DR. WALTER B. LAFFER in the Chair

Gynecologic Problems of Interest to the General Physician

DR. BARTON COOKE HIRST, Philadelphia: Too many lives are lost in this aseptic era from puerperal infection. A well-equipped obstetric bag with sterile contents including gloves, the shaving of patients, cleansing of the vulva before examination and scrupulous cleanliness in the after-management would unquestionably reduce the morbidity and mortality of childbearing. Moreover, physicians should insist on more stringent regulation and instruction of midwives. I wish to emphasize two points in the treatment of puerperal infection —the value of antistreptococcus serum and the possibilities of the operative treatment of pelvic infections. As to lacerations of the birth canal, I believe that only by immediate repair, or at least repair within five days after delivery, can all the injuries be successfully repaired and their consequences avoided.

About one-fifth of all women who consult physicians because of diseases peculiar to their sex, are suffering from retrodisplacements. Every woman after confinement should be subjected to two examinations—one at the end of three weeks when she begins to walk, and the other at the end of the puerperium, six weeks after delivery. If displacement is discovered after the first examination it can be cured, in a certain percentage of the cases, by use of the knee-chest position twice a day. If it persists, at the end of six weeks, a pessary with Swedish exercises and massage will effect a cure in an additional number of the cases. If in spite of this treatment the malposition still persists, early operation should be advised. I must still harp on the sinister significance of genital hemorrhage, especially in the middle-aged, in relation to carcinoma. It cannot be too strongly emphasized.

In the United States 2,500 women die every year from eclampsia—about six times as many as should legitimately do so, if the condition were properly treated. We should watch more carefully for pre-eclamptic symptoms by urinary and blood-pressure examinations—especially the latter as the blood-pressure is invariably raised. It is easier to prevent eclampsia than to cure it. The patient should be placed in a hospital, if possible, and energetic diaphoresis employed from the start. It is a fallacy that the first step in treatment is evacuation of the uterus.

As to moderate-sized fibromyomata, if they are not causing pressure symptoms or excessive hemorrhage, there is always ample time, years in fact, to observe the rate of growth, to watch for untoward symptoms, and to decide whether the neoplasm is a serious detriment to the patient or not. This is, I believe, the right course to follow when practicable. In ectopic gestation, I believe in immediate operation, as I have too vivid a recollection of patients who have bled to death before I could reach them. It is the height of folly to wait for a reaction that may never come. In placentia prævia there are certain rules which might be remembered with advantage. A vaginal tampon, if big enough, will temporarily check the hemorrhage until other measures can be decided on. Version followed by a slow extraction of the fetus is applicable in a majority of the cases. In some cases of sterility, resulting from an infantile uterus, I have obtained excellent results by local electrical stimulation. This is a therapeutic measure that is not so generally appreciated as it might be.

DISCUSSION

DR. HUNTER ROBB: Only by the best aseptic technic can infections, following labor and abortion, be prevented. Every physician should have good surgical training. In my experience, about one-half of these infections are gonorrheal in origin. In perineal tears, if the patient's condition is good, I advise immediate repair. I have never seen a patient bleed to death in ectopic pregnancy; though I have seen many "operated to death." I do not believe in immediate operation. Some patients will stand it, but the majority are in deep shock and are too weak to stand an immediate operation. In the past year, I have had eight more of these cases and the patients all recovered, being operated on in from two or three days to a week or so. If the patients are properly stimulated following rupture of the pregnancy they will not bleed to death. In my experience, a majority of cases of sterility are due to gonorrheal inflammation of the tubes.

DR. W. H. HUMISTON: Retroflexion of the uterus is the most common complication following labor. The majority of lacerations of the cervix heal of themselves, but if there is a mild degree of sepsis present healing is not so rapid and there is a resultant subinvolution of the uterus, with subsequent retrodisplacement. I treat such patients by curettage and repair of the cervix, getting the uterus into position in the knee-chest position, and applying a properly fitting pessary. The patient is kept in bed and is not allowed to sleep on the back. After getting up, the pessary is removed in from eight to ten weeks. In cases of rupture in ectopic pregnancy I wait no longer than it takes me to get the patient into the operating room, and for me to get into the abdomen. By such treatment I have had no fatalities. About 90 per cent. of my operative cases are gonorrheal in origin. In acute cases I believe in radical measures. I put the patient to bed, shave the vulva, wash and cleanse out the vagina with soap and bichlorid of mercury solution. Then I carefully cleanse the cervix with alcohol and swab the cervix and canal with compound tincture of iodin. The vagina is then dried and powdered with boric acid, seven parts to one part of iodoform. After this the uterus is packed with gauze. After four such treatments, in eight days I begin the use of douches of permanganate of zinc. Internally the patient gets a mild diet and hexamethylenamin.

DR. W. H. WEIR: How does Dr. Hirst use antistreptococcus serum? Does he ever use it prophylactically?

DR. J. E. TUCKERMAN: Some cases of retrodisplacement are due to undue anxiety on the part of the physician to keep the patient on her back, following labor.

DR. LILLIAN TOWNSLEE: I used the electric current in one case of infantile uterus. After its use for six months the organ had increased greatly in size and the patient became pregnant, later giving birth to a normal child. I do not favor immediate operation for ruptured extrauterine pregnancy.

Dr. B. C. Hirst: I have seen at least four or five patients who have bled to death following delay in operation for ruptured ectopic pregnancy. At any rate, the patient should be in a hospital where she can be carefully watched. In using serum in the treatment of septicemia I use 80 c.c. at a dose; this is four times the dose recommended by the makers. This dose should be repeated four times a day and may be used for two or three days. Possibly better results are achieved with the use of fresh antistreptococcus serum than with older samples. I agree partly with Dr. Tuckerman that patients may be kept too long in bed; however, I do this with a note of warning, for there is danger of later prolapse if the patient gets up too soon.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

Medical Record, New York

April 1

1 *Vagaries of the Pneumococcus. W. H. Thomson, New York.
2 The High Death-Rate from Diphtheria in the United States. E. C. Hill, U. S. Army.
3 *What Is Rheumatism? H. C. de V. Cornwell, New York.
4 Arthritis Deformans and Its Relation to Intestinal Putrefaction. E. E. Cornwall, Brooklyn, N. Y.
5 The Hospital and the Young Physician. W. E. Darnall, Atlantic City, N. J.
6 *Source of Error in the Diazo Reaction. S. Levinson, Brooklyn, N. Y.
7 A Case of Blood Extravasation Into the Sclera from Indirect Violence. F. Griffith, New York.
8 Short Talks with My Students and Others: Random Suggestions for the Younger Practitioners. R. H. M. Dawbarn, New York.

1. **Vagaries of the Pneumococcus.**—Thompson has become convinced that creosote carbonate, in 15-grain doses, given every two or three hours, in a specially prepared emulsion which is so well borne by the stomach that he has known it to stay down when everything else was rejected, *changes the* course of the fever so that in 70 per cent. of *the cases it ends* by lysis instead of by crisis. The extreme susceptibility of the pneumococcus to the faintest trace of phenol may allow of this preparation being regarded as a true blood germicide. Thomson has seen no injurious effect produced by it even when its absorption causes the urine to become dark. The formula for this emulsion is:

℞	gm. or c.c.		
Acaciæ	18		ʒiv
Aquæ	18	or	ʒivss
f. mucilaginem tunc adde			
Creosoti carbonatis	21	33	ʒv, mxx
Misce et adde:			
Glycerini	30		℥i
Aquæ menthæ piperitæ ad.......	240		℥viii

Sig. One tablespoonful (15 grains of creosote carbonate) *every* 2 or 3 hours.

This is also his favorite prescription for pulmonary phthisis, *not* that he expects it to be operative against the tubercle bacilli, but *against* the pyogenic microorganisms whose alliance with the tubercle bacilli in the lungs is so disastrous.

3. **Rheumatism.**—In speaking of rheumatism, Cornwell says we should never employ the term in the description of a symp*tom, but should* limit its application to the conception of an *acute, constitutional,* self-limited infectious process, with a practically incontestable *bacterial etiology,* a proneness to find focal expression in the joints (arthritic type), or the endocardium (endocardial type), and to a less extent in other tissues, and a tendency to react specifically and characteristically to medication by the salicylates.

6. **Error in the Diazo Reaction.**—When a urine shows the diazo reaction, Levison says it becomes necessary, in order to avoid mistakes, to ascertain whether *the reaction* is not due to phenolphthalein. As the presence of this drug can be easily demonstrated by addition of alkalies it is only necessary to test the urine with a few drops of *some alkali;* a pink or reddish color shows the presence *of* phenolphthalein. If this reaction is negative we have a true diazo reaction. But in case this reaction is positive (the urine becomes red after the addition of alkalies), we may have the phenolphthalein reaction alone, or a true diazo reaction, together with the reaction produced by phenolphthalein. In order to test the urine in such a case of a suspected "mixed" reaction, add a few drops of some acid to the test tube in which there is a positive diazo reaction. If the color disappears altogether and appears *again* only after the addition of enough alkali to render the mixture alkaline, the reaction is due to phenolph*thalein alone. If after the addition* of acid the color becomes lighter, but does not disappear completely and becomes more intense by addition of enough alkali to render the mixture alkaline, the reaction is due to the substance or substances producing the true diazo reaction and also to the presence of phenolphthalein.

9 Trachoma. S. H. Brown, Philadelphia.
10 A Hurried Bird's-Eye View of the Problem of the Modern Care of the Insane. M. Solomon, Washington, D. C.
11 Improvements in the Optical Construction of Cystoscopes. L. Buerger, New York.
12 The Problem of Prostitution and Venereal Diseases in New York City. F. Bierhoff, New York.
13 *A New Method of Direct Transfusion of Blood. A. L. Soresi, New York.
14 *An Unusual Case of Infantile Paralysis. H. G. Harris, New York.
15 A Case of Diabetic Glaucoma and Operation. S. Moskowitz, New York.
16 Treatment of Whooping-Cough. C. L. Henriques, New York.
17 Infundibulin in Hemorrhage Due to Uterine Carcinoma. J. C. Scott, Philadelphia.

13. **Direct Transfusion of Blood.**—The *instrument devised* by Soresi is said to do away with the necessity of *opening the* blood-vessels until they are ready to be brought together, so that the blood *may flow immediately from one to the other.* The surgeon is thus enabled to work on the *blood-vessels* while the blood is circulating in them, that is while the lumen is naturally open because it is full of circulating blood; *therefore the blood-vessels* not being contracted and retracted are *easily* grasped and secured by the instrument. Then *the intima can without any difficulty* be so inverted that the intima of the two blood-vessels can easily be brought in direct contact. Besides the one to be described, no other special *instrument,* hooks, serrefines or needles are necessary. The *instrument is composed of two small metal* cylinders which are put and held *together by means of a small* bar and a screw. Each cylinder is opened on its longitudinal axis by a simple pivot, and at one end, a *little below the edge, is* encircled by a crown of small hooks, the points of *which are* turned toward the other end. The blood-vessel is *cuffed over* the hooks of the cylinder; the vessels are opened and the anastomosis is made. Two cases are reported in which the method was used successfully.

14. **Infantile Paralysis.**—The interesting points in Harris' case are the length and the severity of the acute manifestations; the presence in the urine of the *colon* bacillus; the effect of hexamethylenamin; the symptoms *indicative* of meningitis and tetany; the relief of the symptoms *following* lumbar puncture; the appearance of the paralysis on the tenth day and its disappearance a week later. It is Harris' belief that the symptom-complex tetany is a term *not infrequently* applied to atypical cases of anterior poliomyelitis. Also, that the question of whether colon bacillus *infection* may not cause symptoms characteristic of so-called *tetany,* poliomyelitis or meningitis is worthy of future study.

19 Fibrous Stricture of the Rectum. J. P. Tuttle, New York.
20 *Hemorrhagic Disease of the *New-Born* Infant. R. M. Green and J. B. Swift, Boston.
21 Medical Inspection of Schools in Boston. S. H. Ayer, Boston.
22 A Simple, Quickly Removable Head Bandage. E. C. Hill, U. S. Army.

20. **Hemorrhagic Disease *of* New-Born *Infants.***—This paper is based on a study of fifty-one cases occurring in hospital practice during a period of not quite six years. *The* percentage incidence was 1.14. It was *noted that the* parity and civil status of the mother, the *fetal* presentation, the duration of labor and of complications *of labor and the* puerperium are factors

of no significance as predisposing or determining causes of hemorrhagic disease in the new-born. The seasonal incidence and the occurrence of hospital cases in groups tended strongly to confirm the theory of the infectious etiology of the disease. The earlier the onset of the disease, the worse was its prognosis; after one week, the prognosis became relatively, and after ten days, absolutely, good. Clinically the disease occurred in three fairly distinct types, the umbilical, the seromucus and the purpuric, which have an approximate respective mortality of 60 per cent., 50 per cent. and 22 per cent. The gross total mortality was about 50 per cent. The treatment was directed toward local hemostasis and increase of coagulability of the blood. Gelatin and rabbit serum gave the best results. Of thirteen patients receiving the gelatin treatment, nine recovered and four died. Of twenty-two patients treated with rabbit serum, twelve recovered and ten died. General supportive treatment: two recovered, four died; local hemostasis: two recovered, four died; no treatment; one recovered, two died.

32 Cardiospasm. C. Moore, Los Angeles.

28. **Chronic Cholecystitis.**—Whenever Babcock sees a case of cardiac insufficiency, from whatever cause, he always pays close attention to the liver. Whenever he finds the right lobe showing enlargement he pays particular attention to its outline. He says that in most of these cases when there is tenderness, there is tension of the right rectus and if one palpates with firmness the tension becomes more marked. In nearly all these cases, by supporting the right hypochondrium with the left hand and producing just a slight pressure with the right hand, allowing the patient to take a breath of moderate depth, one can nearly always feel the border of the liver rise over the side of the hand. Then palpating at the outer border of the rectus, and at the side of the rectus one can feel the convex border of the liver. The left lobe is not so plainly palpable as the right. In some cases quick *ballottement* of Riedel's lobe will give the under hand the sensation of a soft body coming against it. With these symptoms and with tenderness Babcock feels certain of his diagnosis. A corroborative sign is Ewald's area of cutaneous hyperesthesia. If one runs a finger or key lightly down the patient's right back and there is left a sticking or pricking sensation opposite the ninth or tenth dorsal spine, the sign is present. It may extend out 2 or 3 inches. Many patients have this cutaneous hyperesthesia and that is a very strongly corroborative sign of chronic cholecystitis. Babcock emphasizes the fact that gall-bladder disease is more frequent than is generally recognized, and that its effects on the heart or circulatory system may be much more pronounced than is suspected, and hence may be a cause of myocardial breakdown.

29. **Acute Diffuse Edema of the Lungs.**—The three cases cited by Yount occurred in women in a fair state of health, suddenly and at night. They were 48, 50 and 67 years of age respectively. All three patients believed themselves dying; two were rescued from "drowning" in their own secretions. Yount believes that one case might be considered as of cardiotoxic origin, but the other two he considers to be of the cardioneurotic type. Frequent, previous examinations of the urine in these cases, failed to show evidence of nephritis in any case. There was loss of radial pulse in all three women for a time, i. e., greatly lessened blood-pressure. Two of the patients died.

44. **A Case of Aneurysm.**—The patient whose case is cited by Sherrill had a pulsating tumor about the size of a small melon situated at the upper part of the thorax, extending from near the median line and just above the level of the clavicle downward and outward almost to the margin of the pectoralis major muscle. This tumor pulsated synchronously with the heart and was distinctly expansile in character. No distinct bruit could be heard over the tumor, but an accentuated second sound of the heart was easily detected. The patient had an almost imperceptible pulse in the left radial and it was delayed somewhat compared to that of the right radial. The pulse of the left carotid was synchronous with that of the right radial; no tracheal tug; no marked dyspnea; no cough and no interference with deglutition or respiration. A diagnosis of subclavian aneurysm was made, and the various methods of treatment were discussed. It was finally decided to ligate the subclavian in the first portion of its course by attacking it from the posterior surface of the thorax. An incision was made along the posterior margin of the scapula about 4 inches long, dividing the skin and the muscles attached to the posterior portion of this bone. It was joined by an incision running from its inferior extremity to the spinous process. A similar incision was carried from its upper end in toward the spine. The soft tissues were dissected from the ribs with the skin and all hemorrhage controlled. The second, third and fourth ribs were removed for a distance of about 3 inches. The intercostal muscles were lifted off the pleura; the latter was gently pushed downward and outward with the finger and the subclavian artery readily came into view as it left the aorta at the level of the fourth dorsal vertebra. A small opening was made in its sheath and the needle was readily carried around it and a No. 3 catgut ligature placed in position. At this point of the operation, it was discovered by the assistants that the pulsation in the aneurysm did not cease. Further search revealed below the origin of the subclavian a rounded mass, seemingly not larger than a small orange, which was pulsating. The ligature on the subclavian being useless was removed. This having been accomplished the wound was closed and the patient left the table in good condition, and within an hour he was conversing freely

with the attendants in the ward. He died ten days later on rising up suddenly in bed to eat his meal. The necropsy demonstrated an aneurysm of the arch of the aorta in its lower portion, which had ruptured into the esophagus. While he failed to accomplish the object desired in this case, the cure of the subclavian aneurysm, Sherrill feels that the procedure employed is feasible and an easy method of access to the first portion of the left subclavian.

55. **Value of Lumbar Puncture.**—Morse believes that it seems safe to conclude from the present data that during the acute stage of acute poliomyeloencephalitis the cerebrospinal fluid is clear and not infrequently under somewhat increased pressure; that it often shows a fibrin clot, which may persist for two or three weeks and perhaps longer; that it always contains an excess of cells; that these cells are chiefly of the mononuclear type, most of them being lymphocytes; and that these changes are present before the appearance of the paralysis. These changes are, however, identical with those found in tuberculous meningitis, the disease with which it is most likely to be confounded. It is true, of course, that the cerebrospinal fluid in the tuberculous meningitis contains tubercle bacilli. They are missed in about 90 per cent. of the cases, however, if the examination is the usual routine one. If tubercle bacilli are found in the cerebrospinal fluid, the diagnosis of tuberculous meningitis is, of course, positive; if they are not found, the examination of the fluid is of no assistance in the diagnosis between tuberculous meningitis and acute poliomyeloencephalitis.

The characteristics of the cerebrospinal fluid in the early stage of acute poliomyeloencephalitis are so different from those in the early stage of cerebrospinal meningitis, in which the fluid is turbid or purulent, contains a large number of polynuclear cells and, as a rule, numerous meningococci—that in Morse's opinion there is no possibility of confusing them. Lumbar puncture is, therefore, of the greatest assistance in differentiating between these two conditions. It is of equal value in distinguishing acute poliomyeloencephalitis from influenzal and pneumococcus meningitis and from meningitis due to the pus organisms. The changes in the cerebrospinal fluid in the early stage of acute poliomyeloencephalitis are so definite that when they are found it is possible to exclude all diseases outside of the meningitides. Lumbar puncture, therefore, provides a most valuable means of diagnosis in this disease. Unfortunately, there is nothing whatever characteristic about the early symptoms of acute poliomyeloencephalitis, and in order to recognize the disease early, before the onset of the paralysis, at a time when treatment might possibly be of some value, it would be necessary to do a lumbar puncture on every sick child. This hardly seems a rational procedure. Treatment can do no good after the appearance of the paralysis, because the harm is then already done. Lumbar puncture at this time simply makes possible the verification of the clinical diagnosis. The value of lumbar puncture in the early diagnosis of acute poliomyeloencephalitis is, therefore, very limited, in spite of the marked changes in the cerebrospinal fluid in this disease. Morse regards the leukocyte count as of little or no assistance in the early diagnosis of acute poliomyeloencephalitis. There is at present not sufficient evidence to show whether or not there is a relative or absolute lymphocytosis in the early stages.

57. Abstracted in THE JOURNAL, June 11, 1910, p. 1996.

58. **A Study of Meningitis.**—In only nine of the sixty cases investigated by Sophian was a correct clinical diagnosis made by the attending physician. In only one case was a diagnosis of meningitis not made. This case was named a myelitis. From this study it is evident that of the true inflammations of the meninges, tuberculous meningitis is the form most frequently encountered (sixteen cases), and most often confused with the other forms, especially with epidemic cerebrospinal meningitis. Of the conditions simulating meningitis, Sophian found bronchopneumonia in children, especially those forms with apical lesions, most often mistaken for meningitis. Other conditions were gastro-enteritis, other acute infections, such as typhoid, and other conditions of the central nervous system, such as cerebrospinal lues, and anterior poliomyelitis. Sophian believes that in the majority of cases tuberculous meningitis can be diagnosed clinically; the clinical picture is, as a rule, very definite and distinct. Epidemic cerebrospinal meningitis has also, as a rule, a definite and distinct symptom-complex. Still, the two conditions, while frequently easily differentiated, may sometimes so closely resemble each other clinically, especially in the late stages of cerebrospinal meningitis or the early stages of tuberculous meningitis, that it may be impossible to make a clinical differential diagnosis. The other acute forms of meningitis, those caused by *Streptococcus pyogenes*, *Streptococcus mucosus capsulatus*, the pneumococcus, and *B. influenzæ*, present almost the same symptom-complex as epidemic meningitis. The history of previous disease, such as otitis media, may be of some help, but the diagnosis can only be established definitely by lumbar puncture and examination of the cerebrospinal fluid. Meningism complicating other acute infections, while sometimes difficult to differentiate from epidemic meningitis, can, as a rule, be diagnosed. Polioencephalitis often resembles tuberculous meningitis clinically; however, here the local palsies, such as hemiplegia are extensive and permanent.

Blood count is of aid in diagnosis. The principal features are, in the cerebrospinal form, the high leukocytoses of 20,000 or more, with the high relative polynucleosis up to 99 per cent. In the tuberculous meningitis is seen a moderate leukocytosis, up to 18,000 or occasionally more, with a moderate relative polynucleosis up to 80 per cent. or more. Poliomyelitis and polioencephalitis in the febrile stage show a slight leukocytosis; meningism secondary to another disease of course gives a blood-count depending on the disease causing it. Sophian urges that once a clinical diagnosis of meningitis is made, whatever the form, a lumbar puncture should always be performed. A clinical diagnosis is never certain and even with a complete picture of a type of meningitis errors may be made. A study of the cerebrospinal fluid will, in the case of acute suppurative meningitis, enable one at the first examination, as a rule, to find the infecting organism. The very unusual exceptions are rarely in the very onset of epidemic cerebrospinal meningitis, before the organism is free in the cerebrospinal fluid, or, as already mentioned, a localized meningitis, as the localized pneumococcus meningitis mentioned in Holt's cases. It is important, especially in meningococcus infection, when a positive culture is desired, to subinoculate the sediment on suitable culture media as soon as possible after withdrawal from the canal. In tuberculous meningitis in a very large percentage of cases the bacilli can be found in the cerebrospinal fluid at some time during the course of the disease, usually the first examination being sufficient to demonstrate the organism. When one can put the cerebrospinal fluid aside immediately to obtain the unbroken fibrin network, as was done in Hemenway's cases, the chances of finding the bacilli are much larger. Animal inoculation in positive cases, where bacilli have not been found, produces tuberculosis in four to six weeks.

Cytologic examination is extremely important. The increase in the number of cells in inflammatory meningitis is constant; in the suppurative forms of meningitis the preponderance of polynuclear leukocytes is striking; in the late stages of cerebrospinal meningitis, however, as in chronic basic meningitis, a relative lymphocytosis is present; in tuberculous meningitis the excess of lymphocytes up to 100 per cent. is marked; occasionally, however, one will see a tuberculous fluid, in which bacilli have been found, which is cloudy and shows an excess of polynuclear leukocytes, up to 90 per cent. The gross fibrin content of the fluid after standing is a fairly constant guide, there being an increase in meningitis, and very little fibrin in normal fluid. The reduction test of Fehling's solution has been found of no value by Sophian. Noguchi's globulin test, in a small number of fluids examined, was substantiated in inflammatory condition, a positive reaction being present, indicating an increase of the globulin content in the cerebrospinal fluid.

60. **Typhoid Infection.**—The case reported by Elmer was that of a young girl who was infected with typhoid, but who resisted the infection, except for one organ, namely, the gall-bladder, and her illness in his opinion was due solely to the cholecystitis. That she was infected with the poison of typhoid, he says, there can be no doubt, because eleven other patients who had been drinking milk from the same dealer developed typhoid in its characteristic form. About eighteen days after she had ceased to drink the milk, she developed a little fever. She had no nose-bleed, no vomiting, no pain in back or limbs, but had not felt well for some weeks. She had pain in the right side of the abdomen. The edge of the spleen, when a full inspiration was taken, could just be felt but was very indefinite. The gall-bladder could easily be palpated; it was distended and very tender. The temperature ran an irregular course, with marked daily remissions, reaching 103 F. or a little more in the late afternoons. Pulse varied from 80 to 100. Leukocyte count was 7,000. The patient did not seem ill, was usually hungry, was in good spirits most of the time, and had none of the apathy which usually results from the toxemia of typhoid. The urine was normal. On the seventh day, Elmer found three typical rose spots on the abdomen, the first that had appeared; and on the following day he obtained a characteristic clump reaction with a dilution of 1 to 50. The complete relief from all symptoms when the gall-bladder began draining, and the absolutely normal temperature which began about thirty-six hours later and continued without variation all through the convalescence, and the fact that the patient seemed and felt perfectly well from the time the gall-bladder was relieved, led Elmer to the conclusion that there could be no sloughing intestinal ulcers or extensive lymphatic involvement.

70. **The Succus Entericus.**—In experiments on dogs, Mosenthal noted that a nitrogen equivalent to about 35 per cent. of the nitrogen intake, though not necessarily derived directly from it, is daily secreted in the succus entericus in dogs on a mixed diet; about 10 per cent. is excreted in the feces, and about 25 per cent. is reabsorbed. The amount of reabsorbed nitrogen-containing material is considerably larger, if the bile and pancreatic secretion are included. Mosenthal says that the metabolic significance of this reabsorption can only be surmised. That it is probably of great importance is indicated by the fact that in the experiments recorded by him, the amount of nitrogen reabsorbed equaled approximately 25 per cent. of the nitrogen intake.

71. **Absorption from Intramuscular Tissue.**—Because the correctness of their previous work on absorption from intramuscular tissue was questioned, Auer and Meltzer repeated their experiments, proving again that the absorption after intramuscular injections is far superior to that after injections into subcutaneous tissue, approaching in its effectiveness that of an intravenous injection. The experiments were made on rabbits, and the results obtained were constant.

72. **The Interstitial Cells of Leydig.**—It is claimed by Hanes that the mammalian testicle elaborates an internal secretion necessary to the normal development of secondary sexual characters. The spermatogenic cells play no part in the formation of this secretion. One function of the Sertoli cells is to supply fat to the developing sperm cells. In the absence of the sperm cells from the mammalian testicle, fat accumulates in large amount in the Sertoli cells. The Sertoli cells seem to take no part in the production of an internal secretion. The interstitial cells of Leydig are, in all probability, responsible for the production of an internal secretion of the mammalian testicle.

89. **Opium Poisoning.**—The patient in this case took a 2-ounce mixture of tincture of opium and tincture of arnica, equal parts. At 4 p. m., four and a half hours later, her husband found her in a deep sleep, and seeing the empty bottle, immediately aroused her and administered warm mustard water until vomiting was induced. Strother reached her at 4:30 p. m. He found her awake and rational, though very

drowsy. Pulse was 136 and small; respiration was 26; the pupils were pin-head in size. She complained only of nausea and vomiting. Strychnin, 1/30 grain, and atropin, 1/150 grain, were given hypodermically, and a cup of hot black coffee by mouth, the latter being soon vomited, but the dose was repeated. During the ensuing three hours, the pulse-rate gradually fell to 120, with better volume, and respiration to 20, when Strother repeated the strychnin, 1/30 grain, omitting the atropin. After another three hours the pulse was 96 and of fair volume, and respiration was 17. At the end of six hours more, the pulse was 68, and respiration was normal. Strother asks: Was the tannin content of the arnica sufficient to antidote the morphin in the laudanum chemically, or did the depressant effect of the arnica on the vagi antidote the opium physiologically?

97. **Action of Gossypii Cortex.**—The effect of this agent on the uterine contractions was studied by Scott. He found that the drug acts as well on the excised uterus as on the uterus with blood and nerve supply intact. In view of the extremely uncertain properties and keeping qualities of ergot and its preparations, and the fact that gossypii cortex is stable and very active, as shown on the cat's uterus, Scott thinks this drug is deserving of a more extended clinical use in the class of cases in which ergot is indicated.

107. **Arterial Hypertension.**—The systolic blood-pressure was carefully taken by Peter in 104 cases, mostly chronic interstitial nephritis, in which there was a neuroretinitis or a retinitis. For purposes of comparison nine cases of syphilitic neuroretinitis are included in the report, showing an average blood-pressure of 132 mm. of mercury and three cases of chronic parenchymatous nephritis with an average pressure of 132 mm. The average pressure in twenty cases of retinitis was 165 mm.; in fifty-nine cases of neuroretinitis it was 185 mm.; in three cases of albuminuric retinitis, 190 mm.; in six cases of hemorrhagic retinitis, 205 mm., and in three cases of papillitis, 225 mm. Thirty-three of the ninety-four kidney cases occurred in men and sixty-one in women. The higher pressures were observed relatively much more frequently in men than in women. Peter concludes that arterial hypertension is the chief cause of the eye-ground phenomena observed in chronic interstitial nephritis and arteriosclerosis. Similar vascular changes, associated with high blood-pressure, may, he says, be observed at times, before these diseases are diagnosed by other clinical symptoms. It frequently acts as a cause for subconjunctival hemorrhage and is so closely associated with glaucoma that it should be regarded as an active factor in the development of the disease. The author urges that in order to prevent and to treat rationally the more serious eye conditions, routine blood-pressure studies should be made in all cases of intra-ocular disease not traumatic in origin.

122. **Anomalies of the Colon.**—It is believed by Eastmond that abnormal conditions of the colon are frequently the cause, not only of persistent constipation, but also of the vague, indefinite abdominal symptoms and the nervous conditions so often seen and so hard to attribute to any definite diseased entity. The anomalous conditions of the colon are summarized by him as follows: (1) general prolapse of the transverse colon producing the "U" or "V" type; (2) prolapse of the hepatic or splenic flexure with or without angulation; (3) angulation of any part, especially of the sigmoid; (4) prolapse of one-half of the entire colon; (5) general prolapse of the entire colon into the pelvis; (6) spasm of one part or of the entire colon; (7) anomalous development of any part, such as a loop formation from the presence of an unduly long mesentery; (8) adhesions, either alone or associated with any of the above conditions. In all these conditions, there is some factor which is sufficient to produce partial obstruction and damming back of fecal stream. In the cases of adhesions and angulations, there is almost uniformly found a dilatation behind the obstruction. This, with the ensuing stasis, affords ample opportunity for undue absorption of intestinal material, auto-intoxication, with its headache, drowsiness, listlessness, etc. With prolapse, the displaced portion of the viscus, by dragging on its natural supports, is productive of backache, and with the interference in circulation and ennervation, there follows congestion, inflammation, spasm, local pain and tenderness, and that train of nervous phenomena which is termed neurasthenia. The value of

Roentgen-ray examination in these cases lies, first, in the detection of the true state of affairs, and second, in the determination thereby whether it is a purely medical one that may be relieved and possibly cured by general and local treatment, or whether operative procedures will be necessary to secure the desired results.

145. **Digitalis and Its Allies.**—There is no question in Cushny's mind that digitalis and its allies are too much feared by the medical profession. The "cumulative" action, he says, has been held over us as a bogey for so many years that many prescriptions contain this valuable drug in harmless and useless doses. As regards their relative usefulness, he says that there is little difference between digitalis, squills or strophanthus. We get the same beneficial results and the same undesirable ones as regards the heart, and a patient who shows symptoms of heart block under digitalis suffers from the same irregularity under squills or strophanthus, while when extra-systole is induced by one it follows from all. Strophanthus is often said to have less tendency to raise the blood-pressure than digitalis, but in patients neither induces any rise of pressure, and in some individuals, both cause an equal fall. There is, on the whole, rather less tendency to headaches, nausea and vomiting under strophanthus and squills than under digitalis, but the difference is not very marked and headache is caused in some cases by all three. Slight diarrhea has followed the use of squills more than the others, and strophanthus also tends to cause this more than digitalis. This tendency to diarrhea is still more marked from the use of helleborin and apocynum.

In animal experiments, one of the characteristic effects of digitalis medication is the rise of blood-pressure, which arises in part from the heart action, and in part from a constriction of the arterioles. In patients the blood-pressure is rarely augmented by digitalis and may in fact fall as the general improvement sets in. This, Cushny thinks, is due to the much greater efficiency of the vasomotor mechanism in man, which has been developed to permit of his assuming the erect attitude. As the heart fails in disease, the organ which first suffers is the brain; but anemia of the brain is promptly remedied by constriction of the abdominal vessels, by which the blood is again directed to the head areas. If digitalis is then given and the heart action improves, the first effect would be to increase the blood-supply of the brain, and this leads the sentinel in the medulla to relax its vigilance, the mesenteric vessels are allowed to relax and the improvement in the heart may thus be coincident with lowered blood-pressure. In his experience there is no significant increase in the amount of urine, except when dropsy is present.

147. **Physiology of the Pituitary Gland.**—The chief idea brought out by Wiggers is that the anterior lobe of the pituitary gland evidently elaborates a secretion that is necessary to life and to normal metabolism and development. This substance has so far resisted extraction by various solvents, hence its chemical nature and physiologic properties remain unknown. The posterior lobe, which is not of vital importance, contains or secretes a substance that may be extracted by water, glycerin or salt solution, and resists boiling, but it has not been demonstrated that it is identical with the secretion of the anterior lobe or that it represents its vital principle. The extracts constrict the peripheral vessels (probably by a direct muscular action), thus producing a marked rise of arterial blood-pressure. This constriction is not equally pronounced in all organs, for the renal vessels are, at least passively, dilated during its action. These extracts are generally stated to slow and strengthen the heart, but myographic tracings of the intact and perfused heart made by Wiggers, indicate a depressing influence to be the most constant and characteristic one, an increase in the amplitude being only exceptionally the case. The slowing, as well as depression, are, he thinks, largely attributed to a direct cardiac action, but the former may be augmented by a vagus effect. Pituitary extract resembles adrenalin in its action only in that it causes a rise in blood-pressure. The manner in which they affect the heart and blood-vessels, as well as the effects induced, are entirely different. In addition to its cardiovascular action, pituitary augments the secretion of urine and inhibits the flow of pancreatic juice, but it has not been definitely determined whether these varied reactions are due to separate substances, to a specific affinity of a single substance for different cells, or whether they are secondary to changes in the circulation.

148. **Stiff and Painful Shoulders.**—A periarthritis from tears of the axillary portion of the shoulder capsule, due to forced abduction, in Thomas' opinion offers the best explanation of the stiff and painful shoulders, with loss of power in the arm, variously diagnosticated as fibrous ankylosis, neuritis, paralysis of the deltoid, traumatic arthritis, etc. The most characteristic feature is a scapulohumeral limitation of movement, sometimes slight, often marked, but never complete. The associated loss of power and atrophy are due in part to disuse, but probably in most part to the perineuritis, neuritis and resulting adhesions and compression of some or all of the brachial nerves in the axilla, adjacent to the wounded joint. The audible and palpable tearing which accompanies the breaking up of the limited abduction and external rotation, in chronic cases, by the leverage of the arm, under an anesthetic, is produced not by the tearing of fibrous adhesions in the bursa, but of the axillary portion of the capsule shortened by cicatricial contraction in its relaxed condition. This bursa is circumscribed to the upper surface of the greater tuberosity of the humerus and the adjacent small portions of the rotators inserting into it. When the bursa is inflamed, Thomas says, the diagnosis should easily be made by the acute tenderness localized to the upper surface of the humerus, directly in front of the acromion, when the arm is in the position of rest, that is, adduction and internal rotation, which it practically always occupies. The capsule lesion is typified by that which occurs in an anterior dislocation of the shoulder, the frequency of which is nearly as great as that of the other dislocations of the shoulder combined.

Those cases of stiff and painful shoulder in which there is no history of dislocation are explained, in the first place, by the spontaneous reduction of many dislocations as the arm falls from its abducted position to the side of the body, so that they are not recognized as such; and in the second place, by the much greater frequency of milder but similar tears (sprains) from forced abduction, which are not sufficiently extensive to permit the occurrence of a dislocation. Sprains are rarely recognized in this joint, because they are peculiarly obscure as to their etiology and symptomatology. At the moment of the forced abduction the patient is excited and does not appreciate the relation between this movement and the pain it produces, the capsule being poorly supplied with nerves and the pain at the moment probably being slight. The arm immediately drops to the side into the position of most complete relaxation of the torn portion of capsule, and is kept there afterward because of the pain produced by abduction and external rotation which drag on the seat of injury. The lesion is deeply seated and localized with difficulty, and the disturbances which follow are misinterpreted. The most rational method of treatment is that which aims at increasing the length of the contracted tissues to the normal, favors the absorption of inflammatory material, and increases the power of the weakened and atrophied muscles.

150. **Paralysis in Pott's Disease.**—Four cases are reported by Cadwalader. Three terminated fatally and a careful postmortem examination was made. They presented swelling and destruction of axis cylinders, proliferation of the glia, round-cell infiltration, sclerosis of the blood-vessels, perivascular infiltration, necrotic softening of the central gray matter, and compound granular cells at the level of greatest compression of the spinal cord. In one case there was an internal hydrocephalus affecting only the lateral ventricles; the foramina, however, were not occluded, but the cells of the chorioid plexus were decidedly diseased; it is conceivable, therefore, that as a result of perverted function of diseased cells there may have been an increase of secretion sufficient to cause this distention. But it is also possible that hydrocephalus may have been the result of compression of the cord, and that if an ophthalmologic examination had been made, choked disk would have been found. At other levels of the spinal cord where compression seemed to play no part, there were definite though very moderate signs of vascular disease, consequently it might seem as if there was some other element responsible as well as compression. After searching the literature on this subject Cadwalader was able to find only two cases described in which paralysis developed instantaneously without deformity of the vertebræ.

152. **Sarcoma of the Vagina.**—McFarland presents a very comprehensive statistical study of 102 cases and reports a new case of grape-like sarcoma of the vagina in an infant.

153. **Tuberculosis of the Lungs.**—Despite the pathologic findings, Walsh believes that clinical tuberculosis, that is, tuberculosis in individuals with some susceptibility, begins more commonly at the top of the right lung. A study of the progression of tuberculosis of the lung on autopsies at the Phipps Institute showed that in the cases in which it was possible to judge the progression, the progression commonly corresponded to what Walsh has pointed out as the most fatal, clinically; in other words, the majority of cases showed progression practically throughout one side before the other was involved. Lesions involving the whole of one lobe of the left lung usually give better results than lesions of the same size in the right lung. One reason for this appears to be that the large lesion on the left more frequently represents the secondary development in a somewhat resistant case. Lesions involving an amount of lung tissue the size of the left upper lobe give a better prognosis when the opposite side shows a chronic healed lesion.

1. **Aphasia.**—Saundby believes that it is difficult to escape from the amount of evidence brought forward to show that destruction of the third frontal convolution, even on both sides, does not cause aphasia; but almost equally cogent, and even more abundant, he says, is the evidence that aphasia occurs in cases in which this convolution is intact. The usual answer in this evidence is that while it may appear intact, it is not so really. Marie has lately reported three cases of this kind in which the convolution was examined microscopically by serial sections without any lesion being discovered. The only rejoinder that the supporter of Broca can make is that the lesion is functional in character, and reveals itself by no change which can be detected by present means of research. But, continues Saundby, those who make this assertion must bear the onus of proof, and it is not easy to produce evidence in its favor. If the convolution of Broca is the seat of the faculty of language, its destruction should be invariably followed by the loss or impairment of that faculty; further, when there is loss or impairment of the faculty of language, this convolution should show always some demonstrable change; if neither of these relations exist, then the only possible verdict must be that the existence of the supposed relation is not proved.

2. **Hereditary Congenital Word Blindness.**—The first case cited by Hinshelwood, that of a girl, is a typical case of abnormal difficulty in registering in the brain the visual symbols of letters and words. She has now, after seven years of teaching in the ordinary way, acquired the visual memories of the most common monosyllabic words. Hinshelwood has seen cases in which after seven years of ordinary training, the child had practically acquired nothing so far as the visual memory of words and letters is concerned. He regards the case of this girl as a mild case of congenital word blindness and, if taught in the proper way, he is certain that she will soon be able to read fairly well. The second case, that of a boy of 10, is of a much more severe type, and the difficulty has been much greater than in the case of the girl, as, after four years' sim-

ilar training, the boy has acquired scarcely any visual memories of words or letters, not even recognizing by sight all the letters of the alphabet. An important point in this case is that the child has experienced the same difficulty in dealing with figures. Hinshelwood says that pure congenital word blindness, which is a local affection of a limited cerebral area, can always be overcome by perseverance and proper methods of education, and herein lies the great importance of the recognition at an early period of the true character of such cases.

5. **Angina Pectoris.**—In one case cited by Verdon, the patient, a man of 63, when seen had been suffering from an anginal seizure for half an hour. He had been making ineffectual efforts to expel wind from his chest, and allowed the introduction of an esophageal tube, a procedure which resulted in an exhaustive liberation of gastric flatus. The effects of the operation became instantly apparent in the altered aspect of the patient. His color returned, and he seemed no longer in pain. The seizure was manifestly at an end. On two occasions he again resorted to the operation of gastric deflation, and on each he brought the seizure to a sudden and abrupt close. The patient had suffered from anginal seizures from time to time for several years; the first severe attack occurred in 1908. When a seizure has been brought to an abrupt and complete termination by the introduction of the esophageal tube, and when later seizures have shown themselves amenable to a similar operation, Verdon thinks the fact that the seizures are the result of tension of the gastric atmosphere is demonstrated beyond question.

6. **Cane Sugar in Heart Disease.**—That glycogen is essential to healthy, well-nourished muscle is shown by the fact that it furnishes a source of energy for the needs of the tissue cells, and particularly for muscle work. The glycogen of a muscle disappears in proportion to the work done by the muscle, and prolonged muscular work, especially in starvation, may wipe out quickly the entire store of glycogen in the body. All modern physiologists agree that glycogen stored up in a muscle is converted into dextrose by an amylolytic ferment before being actually used for producing muscular energy. Such a ferment has been discovered by Nasse. In cane sugar, therefore, Goulston believes that we have a simple means for supplying the muscles with dextrose for the purposes of their activity. Dextrose, he declares, is capable of nourishing the heart muscle in a wonderful and peculiar manner. In his hands the good effect of taking cane sugar to improve the nutrition of the musculature of the heart has been quite in accordance with what was to be expected from the known physiology of the subject. He cites seven cases illustrating the clinical value of this mode of treatment. His cases include two of dilated heart in patients of advanced age; two of valvular heart disease; one each of postinfluenzal dilatation of the heart, heart strain and heart failure in pulmonary tuberculosis. Goulston uses granulated cane sugar, the patient taking as much as desire may dictate. Only occasionally was there a trace of sugar in the urine.

17. **Polypeptids and Gastric Contents.**—In connection with an investigation on the peptid-splitting action of pathologic fluids, the test proposed by Neubauer and Fischer has, in the authors' hands, yielded results suggesting an advocacy for that extended use which alone can determine its permanent utility. They say that it has yet to be demonstrated that the endo-enzymes of cancer cells possess abnormal characters and activities.

18. **Iodin Sterilization of the Skin.**—The observations made by Turner and Catto confirm the value of the iodin method of sterilizing the skin. They made careful bacteriologic investigations in thirty-two cases in which varied operative procedures were resorted to. In certain cases the B.P. tincture (2.5 per cent.) was employed, and in others the following solution: iodin, 30 gms.; potassium iodid, 40 gms.; distilled water, 500 c.c. Before using, this was diluted with an equal volume of methylated spirits, so that the strength of the solution was 3 per cent. For the satisfactory action of the iodin it is essential that the skin be dry. Shaving should be done with a sharp razor without lathering the skin or, if soap and water are used, the skin must be subsequently dried with a pad or towel and then washed over with ether and again dried before the iodin solution is applied. In acute cases the whole process is carried out on the operating table after the patient has been anesthetized. In ordinary cases the preparation is carried out in the ward. The iodized area is then covered with a pad or towel. Before commencing the operation a second application of the iodin solution is made, the skin being now in a thoroughly dry condition. In the thirty-two cases quoted in which the patients were prepared in this manner, a thin strip of the whole thickness of the skin was removed immediately after the first incision and conveyed to the laboratory in a sterilized test-tube plugged with cotton-wool. The investigation consisted in cultivating the piece of skin in nutrient broth for a period of seventy-two hours. At the end of twenty-four and forty-eight hours respectively, the culture was looked at, and at the slightest suspicion of turbidity, "hanging drop" preparations were made and examined. If the fluid remained clear the cultivation was allowed to proceed until 72 hours had elapsed, when it was always examined, both macroscopically and microscopically. In the cases in which microorganisms were present nutrient agar tubes were inoculated from the broth and the particular bacterium further studied and identified. In no case did the culture show the presence of contaminating organisms from the air. Healing was by primary union except in three acute cases in which drainage was necessary. In none did the iodin produce any dermatitis. Though the incisions were made in very varied situations, it is interesting to note that in the three cases in which the skin was infected the wound was in the groin.

24 *Venous Murmurs Heard at the Root of the Neck in Children. C. Coombs.
25 Difference Between Manifestations of Rheumatism in Childhood and Adult Life. J. B. Barrett.

22. **Splenomegaly With Recurrent Jaundice.**—An investigative study has convinced Weber that moderate splenomegaly in children of from 5 to 16 years of age may be almost the only evidence of an inherited syphilitic taint, but in such cases Wassermann's seroreaction for syphilis (if available) would doubtless generally give a positive result. Other evidences of inherited syphilis are occasionally forthcoming; the teeth may be more or less of the Hutchinsonian type, there may be interstitial keratitis, persistent cracks at the corners of the mouth, a history of syphilis in the parents, or of inherited syphilis in brothers and sisters. The splenomegaly of inherited syphilis is often accompanied by occasional (usually only slight) attacks of obstructive jaundice and by excess of urobilin (and urobilinogen) in the urine. Hepatic cirrhosis, with or without ascites, may be associated with the splenomegaly, and at the time of death the hepatic cirrhosis in such cases is probably usually of the ordinary multilobular "hobnail" type. Though it seems doubtful that the cirrhosis of the liver in these cases is of specific syphilitic origin, it is quite possible that the presence of an inherited syphilitic taint may diminish the resistance of the liver toward the action of toxins (including alcohol) and render it specially liable to cirrhosis. The inherited syphilis in these cases may be—

but often is not—associated with some degree of "infantilism," i. e., more or less retardation in general physical development and especially in the sexual functions. In these cases great caution must be employed in regard to antisyphilitic, especially mercurial, treatment, probably on account of the general delicacy of the patients and their liability to renal and catarrhal complications. Iodid of iron seems to be useful. In these cases there is generally very little real anemia, even when the general appearance of the patient is cachectic; and anemia, if present, is often only temporary. In some cases, on the contrary, there may be a certain amount of polycythemia, probably of reactive nature, sometimes sufficient to constitute a symptom-complex, which might be termed "splenomegalic polycythemia of inherited syphilis in children." Other unknown (toxemic?) conditions may cause splenomegaly and recurrent jaundice in children, similar to that met with in cases of inherited syphilis. Abdominal crises (pain, etc.), of uncertain explanation, may occur occasionally both in the inherited syphilitic and in the other cases. Cases of "familial" splenomegaly occurring in two or more brothers or sisters may occasionally be connected with an inherited syphilitic taint, but familial splenomegaly in children is better recognized in connection with congenital chronic acholuric (so-called hemolytic) jaundice, and with primary splenomegaly of the "Gaucher type." Splenomegaly in children may be the most important sign of the presence of hepatic cirrhosis, when the former is either secondary to, or due to the same cause as, the latter. Some cases of splenomegaly in children with inherited syphilis probably ultimately present the characteristic, clinical features of splenic anemia or Banti's disease.

24. **Venous Murmurs.**—In a majority of children varying in age from 3 to 15 years, Coombs heard a murmur immediately below the sternoclavicular joint or joints. It was slightly commoner in boys. It was commoner and louder on the right side. This murmur was continuous, but accentuated at the beginning of systole and of diastole, especially the latter. It was at its loudest during the inspiration. Though often heard with the head in the erect position, it was in such cases heard more clearly, and in some other cases heard only, when the head was fully retracted. Lateral rotation of the head also made it more clearly audible. It is usually abolished when the patient lies down. It is produced in the internal jugular veins; by what mechanism is not clear to Coombs, though its accentuation by retraction of the head is no doubt due to the flattening of the veins against the transverse processes of the cervical spine. Though associated with anemia and febrile states, it is heard also in perfectly healthy children. It is not especially associated with tuberculosis or any enlargement of the intrathoracic lymph glands, and has no diagnostic value.

40 *Recalcification Treatment of Tuberculosis in Children. J. Comby.

37. **Septicemia in Scarlet Fever.**—In the case reported by Hutinel the scarlet fever accompanied varicella. The principal scarlatinal lesions were in the throat and mouth and the mucosa sloughed off at several points with general symptoms of septicemia, rapidly proving fatal. The viscera were found practically sound but the thyroid, suprarenal capsules and pituitary body showed marked lesions entailing defective functioning. The symptoms of the varicella and of the ordinary scarlatinal syndrome were comparatively mild; he had encountered this combination in twenty other cases previously, none showing any signs of extra virulence on the part of either infection. The extreme virulence in the case reported was evidently due to the influence of the scarlet fever on the ductless glands. He reported last year a case of acute inflammation of the suprarenals during scarlet fever in a little girl who recovered. Tixier found both suprarenals destroyed by hemorrhages and the pancreas gravely affected, at necropsy of a child succumbing to malignant scarlet fever, and Comby has since encountered a similar case except that the pancreas was intact. Hutinel believes that the scarlatinal lesions in these ductless glands modify the composition of the blood and that this in turn permits the streptococci to enter the blood. In other cases the liver may be the organ to feel the influence of the scarlatinal infection most severely. Treatment should be guided by the signs indicating which of the internal organs are bearing the brunt of the infection—the liver if there seems to be hepatic derangement; the suprarenals if they seem to be at fault. In the latter case epinephrin may be indicated. In either case, baths to reduce excessive temperature and means to cleanse the throat without irritating it and to sustain the heart may all prove useful.

38. **Hypertrophy of the Breasts at Puberty.**—In the case described by Caubet, the mother had had similar hypertrophy of the breasts at puberty. No treatment is effectual except removal of the breasts and this was done in twenty-five cases on record, which he summarizes. The results were good in every instance. The breasts weighed each from nearly 2 to 8 kilos, that is, from 5 to over 17 pounds. In Caubet's case the breasts were shaped like watermelons, and reached below the umbilicus. His compilation includes only the cases developing at puberty; the lesions were simple hypertrophy of the elements of the gland with passive edema.

39. **Clinical Signs of Hypertrophy of the Thymus.**—D'Oelsnitz analyzes ten cases in which the thymus was excessively large for the patient's age and seven other cases in which its hypertrophy was suspected. Three of the patients died from sudden suffocation from this cause; some difficulty in breathing had been noticed before but had not been traced to its true source. These cases teach the importance of examining the thymus whenever no other cause can be discovered for labored breathing, occasional or constant. The results of thymectomy in time are good. Hypertrophy of the thymus should be suspected with stridulous laryngitis when the croup stridor is of unusual intensity and duration. Epistaxis was noted in one case—probably a result of the local mechanical congestion. An intercurrent infection is liable to increase this congestion and render evident a hitherto latent hypertrophy of the thymus. During the suffocation there is cyanosis of the face, also slight edema of the lids; exophthalmos was pronounced in one case and the fontanelles bulged in the younger children. The cyanotic tint may persist constantly and the children may be dull and apathetic. The veins in the neck may be constantly or occasionally congested. The dyspnea is greater lying down. Symmetrical palpation, especially of the suprasternal fossa, during expiration, is instructive, as also percussion. Primary tracheotomy was done on a mistaken diagnosis in two cases, and secondary to partial thymectomy in another. The results in all were disastrous. Intubation may

be necessary in connection with thymectomy when there is concomitant spasm of the glottis.

40. **Recalcification in Treatment of Tuberculosis in Children.**—Comby reviews what has been published to date on the subject of the deficiency in lime as predisposing to tuberculosis and treatment aiming to restore the lacking lime. Ferrier was the pioneer in this line, and he insists on individual prophylactic measures to prevent waste of lime by decalcifying dyspepsia and gastro-intestinal fermentations, refraining from fats, acids and cheese. Comby gives children twice a day before meals a powder containing calcium phosphate, 0.25 gm.; calcium carbonate, 0.2 gm.; calcium chlorid, 0.15 gm., and magnesia usta, 0.1 gm. After ten days he gives for ten days a teaspoonful of 0.03 per cent. aqueous solution of sodium arsenate, then resuming the powders for ten days, and so on. [Ferrier's method of antiacid and alkaline treatment of tuberculosis was described in The Journal, May 1, 1909, page 1465.] Davel and Ginepro have reported good results with the Ferrier method at Buenos Aires, and Comby endorses the recommendations of Sergent and Letulle. The method does not conflict with but supplements the ordinary dietetic hygienic measures.

February 26, No. 9, pp. 353-408

42 Induced Pneumothorax. J. P. Morat.

41. **The White Line.**—Maurice has been studying Sergent's dermographic sign of suprarenal insufficiency, the white line that follows if the finger nail is drawn along the skin of the trunk. Sergent regards it as a manifestation of abnormally low artificial tension and this, in turn, as the result of insufficiency on the part of the suprarenals. Maurice's experience confirms the interpretation of the white line as a sign of suprarenal insufficiency, but it is also a sign of toxic vasoconstrictor excitability. It indicates not only suprarenal treatment but also restrictive dietetic measures and disinfection of the intestinal tract. Nervous persons presenting this sign should be relieved of nervous strain, especially those with a history of severe diphtheria or scarlet fever or with symptoms of tuberculosis.

46 Localization of Bullets in the Tissues. (Localisation des projectiles dans les tissus.) H. Chaput and Vaillant.
47 *Flat-Foot and Tuberculosis. P. Gorse and Dautheville.
48 *Fleas in Transmission of Plague for Long Distances. A. Raybaud.

47. **Flat-Foot and Tuberculosis.**—Gorse and Dautheville state that thirty-six men out of 498 with flat-foot developed tuberculosis during their military service in their regiment, while there were only 157 cases among the 12,390 men with normal feet. The proportion was thus 7 per cent. among the flat-foot squad and only 1.2 per cent. among the rest.

48. **Dangers of Transmission of Plague to Long Distances by Intermediation of Fleas.**—Raybaud calls attention to recent announcements *that the rat flea, Ceratophyllus fasciatus,* is able to hibernate for a month or forty-five days without nourishment, and that virulent plague germs can persist unharmed in its stomach during this length of time and even longer. He thinks that this fact is of great importance for the transmission of the plague to a distance. The marmot or land otter of northern China and the rats of Manchuria are undoubtedly infested with these and other fleas. When the fleas leave the bodies of the animals that have succumbed to the plague, they may seek refuge in bales of goods or cracks of boxes and live there at a temperature which renders them torpid, practically hibernating, while the germs in their interior maintain their vitality and virulence. In this condition, the fleas may be carried with the freight across Siberia or shipped by water to long distances. As the authorities do not consider it necessary, he says, to disinfect freight, there is nothing to prevent the fleas arriving in good condition in other countries, ready to infect rats or human beings, whichever they happen to encounter.

57 Finer Structure of Ganglion Cells in Ovarian Dermoids. A. Wolff.

52. **Diarrheic Postoperative Peritonitis.**—Holzbach warns that postoperative peritonitis may develop with an insidious course and slight general symptoms, profuse diarrhea being the chief sign of trouble. The peritonitis in these cases is a local infection of the pelvic cavity and can be conquered by prompt measures, walling off the small pelvis from the abdominal cavity above while the secretions are given free outlet. This is ensured by the low transverse incision which he prefers for operations on the ovaries, etc. *During the operation he also makes a point of walling off the pelvis with sponges* as a prophylactic measure. He cites a number of examples from his practice showing the prompt arrest of the diarrhea and subsidence of the peritonitis as soon as an outlet was provided for the pus or other secretions causing the trouble. Since he has made a practice of the above technic, the low transverse incision and the preventive gauze walling off of the pelvis, *he has had no further cases of the kind.*

59. **Importance of Physical Properties of Poisons and Drugs.**—Traube's research on the drop-forming properties of the organic fluids and chemicals has convinced him that the physical properties are of far greater importance than has been previously recognized. He accepts as a biologic law of far-reaching import the phenomenon he has repeatedly verified in his research, namely, that a poison becomes less toxic for the medium as the latter becomes turbid under the influence of the poison—that is, when precipitation is under way. This precipitation may occur in ultramicroscopic form long before it is possible to detect it with the naked eye which has hitherto been the criterion. The greater the toxicity of the poison, the greater the physical changes which it induces in the medium; it follows, hence, that the less the physical changes induced, the less toxic the chemical in question. He believes that this opens new lines of research in pharmacology and therapeutics.

The organism, he is convinced, is a physical machine to an extent never hitherto realized. The phenomena reported throw light, he declares, on the problems of immunity and anaphylaxis. For instance, 1 drop of a one-half normal solution of potassium iodid added to 10 c.c. of a 0.2 per cent. solution of „*Nachtblau*, a colloidal basic dye, causes no change in the aspect of the fluid. It still appears extremely limpid, but this one drop of the iodid has transformed it into a condition of actual anaphylaxis. The mixture is now specifically hypersensitive to potassium iodid so that addition of a single drop more of the same potassium iodid solution is followed by heavy flaking—a specific precipitation.

61. **Iodin and Exophthalmic Goiter.**—Goldflam reports two instructive cases showing the danger of eliciting Basedow symptoms by therapeutic administration of iodin. The resulting disturbances are not the comparatively harmless and transient symptoms of iodism; on the contrary, the iodin seems to exert in these cases a specifically injurious action on the thyroid which persists after suspension and elimination of the drug. He warns that this is liable to occur whether the thyroid is perceptibly pathologic or not, especially with serous meningitis and incipient tabes, as well as with goiter and atherosclerosis. These iodin disturbances are by no means restricted to regions where goiter is prevalent. In his first case, symptoms of serous meningitis had existed for some months when a course of iodipin was instituted and was soon followed by tachycardia, enlargement of the thyroid and tremor of the fingers. In the second case a man of 34, who had been systematically treated for syphilis for years after infection at 20, developed incipient tabes. Considerable improvement was realized under subcutaneous injections of iodipin, when Basedow symptoms suddenly became manifest and were very distressing, particularly the severe diarrhea, emaciation and weakness. After suspension of the drug the symptoms finally completely subsided, proving their connection with the medication.

70 Modified Technic for Wassermann Reaction. (Modifikation der Wassermann'schen Reaktion nach von Dungern.) O. Roth.
71 *Predisposition of Apices to Tuberculosis. (Prädisposition der Lungenspitzen und Inhalations-Tuberkulose.) G. Huguenin. Commenced in No. 6.

68. **Acute Hemorrhagic Pancreatitis.**—Monnier reports the details of four fatal cases with necropsy from his practice during the last eighteen months. Two of the patients were previously healthy druggists, 42 and 45 years old; the third was a drinking sailor, and the fourth an obese woman of 54 with cholelithiasis. The influence of trauma was evident in one case and of an acute intestinal affection in another. The necropsy findings indicate that acute pancreatitis is always accompanied with extravasation of blood into the glandular tissue, injuring it to such a degree that it falls a prey to autodigestion. This in turn leads to production of extremely toxic substances, and the only relief is by early operative intervention. If this is delayed until the pancreas is injured beyond repair, little can be anticipated from it, although Hahn reports recovery when the patient was already in severe collapse; he made a high incision, rinsed the abdominal cavity with salt solution and drained. The main point is to think of the possibility of acute pancreatitis when called to a patient with symptoms suggesting ileus, cholelithiasis, perforation peritonitis or appendicitis. The lack of rigidity of the abdominal wall, the temperature higher than with ileus, the peculiar sallowness and the obstinate pain in the epigastrium speak for pancreatitis, as also the fact that several quarts of water can be poured into the bowel; this generally brings stool and gas. The pain with appendicitis is seldom so intense and persistent as with acute pancreatitis. The persistence of the pain, the rapid aggravation of the condition and the symptoms suggesting ileus are evidence against cholelithiasis alone, although this is usually the primal factor for the acute pancreatitis.

69. **Knee-Elbow Position for Visceral Ptosis.**—Fellenberg remarks that the advantages of the knee-elbow position for correction of ptosis of various viscera is only recently attracting the attention it deserves. He reports a case of recurring attacks of pain and nausea and other disturbances explained only by the discovery of a right wandering kidney. As soon as the patient, a young woman, assumed the knee-elbow position she experienced relief, and she learned to use this as a prophylactic measure, before going out for a walk, for instance. She refuses operative relief and is delighted that she can keep herself free from disturbances by this simple measure. Until this had been suggested she was growing more and more emaciated from the pains and digestive disturbances consequent on the physical anomaly. The pains come on, Fellenberg assumes, at the moment when the stomach content is being passed on into the intestine, the latter being compressed by the movable kidney; the more copious the meal the severer the pain. The kidney drops forward as the patient assumes the knee-elbow position, leaving the passage free for normal evacuation of the stomach. He thinks the same measure might prove effectual in some cases for displacement of the uterus, for mechanical ileus, hydronephrosis, or gall-stone colics and especially for arteriomesenteric occlusion of the bowel.

71. **Predisposition of Apices to Tuberculosis.**—Huguenin analyzes the mechanism of the cough, showing how even under normal conditions it is difficult for the apices to expel secretions and foreign particles. Even at the best they are expelled mostly by the apex being forced up against the roof of the thorax; when there is an unusually small space in the cupola of the thorax the effect is much less and it is least when the apex is already shriveled or indurated. The muscles controlling the cough in this part of the chest are weaker than elsewhere. The bronchial ramifications curve even in a normal lung when the upper part of the thorax has lost its elasticity. With a rigid aperture, the apex may be shut off so that it is quite impossible for it to participate in the act of coughing. When these conditions prevail, the cough may actually force substances up into the apex from the lower part of the lungs, the effect being thus the exact opposite of normal conditions. He discusses further how the child may inherit the phthisical chest from one parent while inheriting unusual resistance to tuberculosis from the other. Wherever tuberculosis may gain a foothold, it gets to the apices almost inevitably sooner or later. The most frequent form of pulmonary tuberculosis is that which originates in infection of the lymph vessels in the neck or chest. In fully 60 to 70 per cent. of his cases the apices had evidently become infected in this way. In only 15 or 20 per cent. was there evidence to indicate direct inhalation as responsible for the apical process. He estimates at less than 20 per cent. the number of cases of pulmonary tuberculosis in children in which infection occurred by way of the intestines. In adults the proportion is much less, under 4.7 per cent. Huguenin does not mention droplet infection in the course of his monograph, as he has never encountered a case, he states, in which there was the least glimmer of probability of this method of origin. But he ascribes quite an important rôle in pulmonary tuberculosis to primary infection by way of the skin and urogenital organs. In his experience, further, fully 79 per cent. of tuberculous bone and joint processes were secondary to preexisting tuberculosis. In this connection, he mentions a family in his charge in which the mother had tuberculosis, and of the six children one had pulmonary tuberculosis, one kidney tuberculosis, one tuberculous glands in the neck, one spina ventosa and phthisis later, and one a tuberculous ulceration on the hand with spina ventosa of two fingers later but no apparent glandular trouble; only one daughter was apparently free from tuberculosis.

72. **Multiple Sclerosis.**—Schultze calls attention to the rise of temperature which generally accompanies the apoplectic *seizures of multiple* sclerosis and differentiates them from ordinary cerebral apoplexy. He warns against the damage that may be done by a mistaken assumption of hysteria as the cause of the disturbances resulting from multiple sclerosis. In a case of the kind no attention was paid to the patient's complaint *that* she became dizzy and felt like falling; she was ordered to conquer this and to exercise as the best means of curing the assumed hysteria. This was the very opposite of what should have been done. Patients with multiple sclerosis should spare themselves any unnecessary efforts, stopping at the slightest fatigue, with frequent pauses for rest. With severe disturbances the patients should stay in bed. Gentle measures are the only ones to apply. A mild course of mineral baths may help by increasing the patient's confidence in himself although the spa physician ascribes it to the waters. The number of drugs that have been used in treatment shows that none is really effectual.

73. **Digestion of Vegetables.**—Schmidt has been unable to discover any evidence to sustain the assumption that the digestion of vegetables occurs mostly in the intestines and that it is mainly the work of microbes. Outside of the body these are the factors involved, but they act very slowly in comparison to the rapidity of the digestion in the body; an ox, for instance, digests 7 pounds of cellulose and hemicellulose in a day, while nothing to approximate this can be realized *in vitro.* The extent of the digestion of cellulose in man, besides, is by no means proportional to the intensity of the putrefaction *processes* in the intestines. *He reiterates* that man stands midway between the herbivora and carnivora; some individuals are to-day more herbivorous while others are more of the carnivorous type. The former can digest even raw turnips, radishes, cucumbers and green salads; while others are unable to digest perfectly even cooked potatoes and beans. These and other facts cited demonstrate, he thinks, that the digestion of vegetables in general depends on the length of time they remain in the gastro-intestinal tract, but, chief of all, on the acidity of the gastric juice. The acid in the gastric juice dissolves the interstitial substance, thus liberating the cells of the vegetable fibers and enabling the alkaline intestinal juices to act on the single cells. When the gastric juice is exceptionally acid, the vegetable cells are separated and the digestion proceeds so completely that the elements of the vegetable cells are all *taken up, leaving no waste to induce* peristalsis—This is Schmidt's explanation of the cause of constipation in certain cases: digestion is too perfect. The gastric juice is only able to dissolve protein, and is unable to do even this perfectly if the amount is *too large.* At the same time this dissolving faculty is *not* the exclusive function of the gastric juice; it is done also and much more thoroughly, he asserts, by the pancreatic juice. It is most injurious therefore for intestinal digestion to have the cells still massed together when the mass is passed on into the intestines. Whether the proteins are dissolved or not is comparatively immaterial. No process below can take the place of the lacking disintegrating action of the acid gastric juice. Undissolved connective tissue in the stools this testifies to the lack of proper gastric functioning in this respect. When the masses of either *meat* or *vegetable* are not *broken* up, the pancreatic juice cannot reach them and *they* linger undigested and afford lurking places for bacteria which in turn set up catarrh. The practical conclusion of the research reported emphasizes anew the *importance* of minute subdivision of the food *when the gastric juice* lacks the normal proportion of acid. The articles of food must be well cooked to loosen the *connective tissue* between the cells, and they must be ground in a *mortar* or *put* through a hair sieve. This mechanical subdivision of the *articles of* food is far more important than any other *feature of the diet,* he insists, and neglect of it soon avenges itself, especially in diarrhea or gastric origin.

77. **Psychopathology of Suicide.**—Sichel *found* evidence of mental derangement in a large proportion of persons who had attempted to commit suicide. *In Munich it* is the rule that every person who makes the attempt is sent to *an asylum for* study of his case. Sichel here reviews the different *forms of* nervous and mental disturbances in these would-be suicides.

78. **Chronic Fibrous Mediastinitis.**—Radonicic reports the details of eleven cases, *classifying them according* as the pathologic process was confined to the mediastinum *proper* or involved the pericardium or had *entailed fusion of the* pericardium. The ages ranged from 14 to 70. Fibrous *mediastinitis* is common, he states, but it is generally overlooked. One sign—the Oliver-Cardarelli—points unerringly to it; this is the downward pulsation palpable in the larynx. He explains the mechanism for this phenomenon which is *observed not only* with isolated fibrous bands in the mediastinum but also with involvement of the pericardium in *the mediastinitis and adherent* pericardium. There may also be a difference in the bloodpressure in the radial arteries in the recumbent *position, this difference* subsiding as the patient stands. This indicates also connective tissue cicatricial changes in the *mediastinum.* In a very few cases a systolic retraction of the chest wall in the entire left scapular region also *may* be *observed* with fusion of the pericardium with the pleura and the heart. This indicates *retrocardial* adhesion and the sign was marked in one of the cases reported. Radonicic has been unable to find any *mention of this sign* in the accessible literature. The fibrous *mediastinitis* was of tuberculous origin in the majority; in *the other cases* there was a history of pneumonia, cancer of the esophagus, rheumatism or syphilis. Anthracosis was encountered but once. Except for the constant difficulty in swallowing, the subjective symptoms were rare and vague; only a few patients complained of a burning pain in the chest or vague sensations back of the sternum. In conclusion, he discusses the interpretation of the radiographic findings.

79. **Gout.**—Cohn explains gout as the result of an overabundance of sodium; this promotes the development and persistence in the *body* of sodium urate which as it is deposited in the tissues forms the gouty tophi. On the other hand, he says, *potassium may be regarded* as an antidote for the sodium; the sodium-urate deposits can occur only in tissues *deficient in potassium,* such as connective tissue and cartilage. These assumptions explain the prevalence of gout among persons whose *food contains* a preponderance of sodium, such as meat, especially rare meat, as blood is one of the substances richest in sodium, averaging 19 parts sodium in 1,000 parts blood. Potatoes, on the other hand, contain the largest proportions of potassium, and those whose food consists mainly of potatoes are thus supplied in abundance with the potassium antidote to the sodium urate deposits.

85. **Serotherapy of Pregnancy Auto-Intoxication.**—Freund has been applying serotherapy for eighteen months in treatment of toxemias of pregnancy and he thinks that his success justifies further trials of the method. He injected from 20 to 80 c.c. of freshly drawn horse serum in six patients with puerperal eclampsia and in each case there were only from one to four convulsions thereafter. He has recently injected the serum from healthy pregnant women near term *into* four

women with serious pregnancy disturbances—a psychosis and dermatosis with uncontrollable vomiting, neuralgia and jaundice in the first case. Marked improvement followed the third day after injection of 24 c.c. of the serum and complete recovery after the second injection a week after the first. This patient was a woman of 24, three months pregnant. In three other cases the eclampsia persisted after delivery; in the first case a total of 58 c.c. of serum was injected during the day, after the twelfth convulsion; seven other convulsions followed, after which the patient, a girl of 15, rapidly recovered. Five convulsions followed the injection of 40 c.c. of serum, preceded by withdrawal of 400 c.c. of blood, in the second case and recovery was uneventful. In the third case the eclampsia did not develop until after delivery and there were no convulsions after injection of 36 c.c. of serum preceded by venesection, after the patient had had eleven convulsions. Freund's experience thus supplements that recently reported by Mayer and Linser with serotherapy of pregnancy toxicoses, but he urges examination of the blood by the optic method in all such cases to obtain a scientific basis for estimation of indications, in addition to the data learned by empiric observation. [Compare Abstract 129 below.]

86. This seems to be the same case previously reported by Ehlers, mentioned in THE JOURNAL, Nov. 26, 1910, page 1941.

100 Medicolegal Diagnosis of Epilepsy. K. Heilbronner. Commenced in No. 9.

89. Local Anesthesia for Major Operations on the Chest.—Hirschel states that at Wilm's service at Heidelberg 487 major operations were done under local anesthesia in 1905 and the number has doubled and more each year since. He gives an illustrated description of the technic for amputation of the breast. He outlines the field of operation with a series of ten injections of the anesthetic, pointing the needle in four directions to spread the fluid. The first puncture in the axilla is the only one that is painful, the others being all at previously anesthetized points.

92. The Mental Disturbances with Chronic Cocain Poisoning.—Higier comments on the fact that the action and symptoms of a single acute poisoning with cocain are very different from those of chronic intoxication. It is not an accumulation of single intoxications, but an entirely different action on the nervous system. In a case described a dentist was taking 5 gm. of cocain daily. Heimann had a case in which 8 gm. was the daily dose and Sollier had a patient who occasionally took up to 12 gm. The needle punctures leave traces of brown almost black pigmentation; this is a sign peculiar to cocain. The paresthesias are not located at the periphery but on the trunk, and they produce the subjective impressions of foreign bodies under the skin. Most characteristic of all is the delirium with hallucinations; it resembles more the alcoholic delirium; but there are no objective signs of liquor drinking. The patient during the delirium can reason logically and behave normally in regard to surrounding objects until unconsciousness supervenes, the condition thus differing from that of ordinary drunkenness. With the cocain there is at first an exalted self-consciousness, followed by dyspnea and distress. Further testimony to the cocain as the cause of the mental disturbances is the favorable influence of morphin; morphin is almost an antidote for cocain poisoning. Higier adds that the hallucinations may drive the patient to commit suicide, which is an extremely rare occurrence in alcoholic delirium, even the most aggressive. Cocain can be suppressed abruptly, he continues; there is little reaction, while recurrence, he says, is rare. He denounces as false the statement in some of the works on toxicology in regard to habitual cocainomania, declaring that cocain addiction is readily curable.

Therapeutische Monatshefte, Berlin

March, XXV, No. 3, pp. 145-208

101 *Study of the Resistance and Ultra-Sensitiveness of the Animal Body to Chemical Agents. H. Hildebrandt.
102 Non-Operative Treatment of Inflammatory Gynecologic Lesions. (Nichtoperative Behandlung entzündlicher Frau- [illegible] Freund.

105 Technic of Intravenous Injection of Large Amounts of Fluids. G. Schwartz.
106 *Tribute to Efforts of the A. M. A. ("Nach amerikanischem Muster"). W. Heubner.

101. Resistance and Hypersusceptibility to Chemical Agents.—Hildebrandt discusses some of the recent additions to our knowledge in regard to anaphylaxis and resistance of the animal body to certain chemicals, concluding with a description of experimental work which seems to demonstrate that the hemolytic action of certain chemicals is annulled by the cholesterin element in the serum. This explains the benefit which Grimm observed in malaria under ingestion of cholesterin; the latter had an inhibiting effect on the hemolytic action of the malarial parasite. Hildebrandt suggests that similar benefit might be obtained in eclampsia from systematic administration of cholesterin. Hemolytic factors are certainly involved in the eclampsia syndrome, he thinks, and possibly the lack of substances with an affinity for fat may be responsible for this; administration of cholesterin might supply this lacking lipophilous substance.

104. Dangers of Hydrotherapeutic Procedures for Infants.—Hanssen reports three out of a larger number of cases in which an ordinary brief warm bath or a mustard pack was followed by threatening collapse on the part of infants 6 or 8 months old, with severe catarrhal enteritis, capillary bronchitis with eczema of the face or in infants convalescing from anemia following long overfeeding with cow's milk. Children entering the hospital should not be given a bath by the nurses before the child has been inspected by the physician or without his orders. If collapse occurs under any hydrotherapeutic measure Hanssen advises repeated injections of camphorated oil, with warm bottles and inhalation of oxygen. It is possible that such accidents from hydrotherapeutic measures are more common in children with the exudative diathesis or, rather, with the neuropathic tendency which generally accompanies it. Czerny has reported sudden fatalities under the first cold pack in neuropathic children. It is wiser, consequently, to refrain from hydrotherapeutic measures altogether with children of this exudative diathesis plus a neuropathic tendency, and especially from mustard packs which in other cases may prove so useful.

106. The Americans Set the Pace.—Heubner comments on the way in which his compatriots frequently wind up a very exaggerated statement by saying: "in true American style." He remarks that he read this expression recently in an article on the fraudulent advertising of certain proprietaries, which, it was stated, was "in true American style." Heubner then goes on to say that he wishes to inform his compatriots that in their attitude toward the abuses in the proprietary medicine business, "they are far behind the stand taken by the medical profession in America, whose American Medical Association has, on its own initiative and with its own forces, successfully organized means to supply every physician with reliable bases for his appreciation of new remedies." He adds: "In connection with the publication of a report of the Council on Pharmacy and Chemistry of the A. M. A., on the fraudulent statements made in advertisements of the preparation Formurol, put out by the Falkenberg firm (Berlin-Grünau), an editorial note states as follows (THE JOURNAL, Jan. 21, 1911, page 210)":

This report illustrates once more the value of the Council on Pharmacy and Chemistry and the Chemical Laboratory to the medical profession. Before the Council was organized there was no agency to protect the physician's interests in the matter of pharmaceuticals. Under the old régime Formurol would have been heralded as a new "synthetic" of the most approved made-in-Germany type—and the claims would have gone unchallenged. To-day its status is made clear and the profession is informed. Only those who have closely studied the question can realize what a wonderful power for commercial probity the Council has proved. Under the *laissez faire* system of the past many large pharmaceutical firms gave little attention to the accuracy of the claims made for their products. If the advertising gave good "pulling" results, that was all that was asked or expected. Within the past five years a wonderful change has taken place in this regard, and firms of the better class have so modified their advertising as to make it not only conservative in tone, but to approximate scientific accuracy.

Heubner passionately exclaims after quoting this editorial note in full: "*'Laissez faire'!* How long, how long is this going to apply to us still in Germany! *(Wie lange wird es bei uns noch so heissen?)*"

112 *Recent Achievements and Problems of Chemistry. E. Fischer.

112. New Achievements of Chemistry.—In this address delivered recently by Professor Emil Fischer he comments on the way in which the discovery of radium has upset the preconceived notions in regard to the unchangeability of the chemical elements, and then remarks that in all this new work on radium the Germans have been merely passive lookers-on. This was owing to the fact that Germany has no radium-bearing ore and that few German scientists have means to purchase the expensive element. But he congratulates his country now on the discovery, by O. Hahn of Berlin, that several radioactive elements are present in the by-products of thorium used in the manufacture of mantle lights. He has isolated the bromid of mesothorium, one of these elements; it has radioactive power similar to radium. The small lump of the mesothorium which Fischer exhibited is equivalent, he stated, to 100 mg. of pure radium bromid, and it cost nearly $3,000. The Berlin Academy of Sciences is soon to have 250 mg. of this mesothorium at its disposal to loan to German scientists. The waste of the thorium manufactures in Germany will produce enough mesothorium annually to be the equivalent of 10 gm. of radium bromid—more than there is of the latter in the world to-day. Then, he intimates, Germany will have something to say for herself on the subject of radium. She was the pioneer in organic synthesis, commencing with Wöhler's artificial production of urea, and he stated that in his laboratory the most complicated substance thus produced by synthesis has recently been perfected. The raw materials for the production of the minute amount yet made cost about $250, but what to-day is merely a scientific toy and curiosity may to-morrow prove of wide practical importance; chemistry has many such fairy-tales to relate. He commented further on the close chemical relationship between the coloring matter of the plants and the blood-pigment. This seems to show a close blood relationship between the animal and vegetable kingdoms. Among the synthetic substances he described as recent achievements in science are synthetic caffein, which is now made extensively from guano, and synthetic epinephrin, made from coal tar.

121 Banti's Disease. K. Ungar.
122 The Cancer Problem. (Das Problem der Krebskrankheit.) A. Fraenkel.

114. Determination of Tubercle Bacilli in Tissues.—Hart and Lessing state that tubercle bacilli do not lose their vitality even when the tissues are cut into frozen sections and treated with formol for half an hour. Animals inoculated with the tissues contract tuberculosis. Even when the frozen sections are stained with hematoxylin and differentiated with hydrochloric acid and alcohol, and after glycerin embedding are dissolved with 15 per cent. antiformin, still the tubercle bacilli are capable of infecting animals. Systematic examination in this way of the entire lymphatic apparatus is liable to throw light on a number of disputed problems. It is their impression that tuberculous infection of children is preeminently a dirt infection, occurring by way of the mouth, throat and intestine, while adults become infected by aspiration of the tubercle bacilli.

117. Glandular Fever.—Schleissner is convinced that what has been called acute glandular fever is very often merely inflammation of adenoid vegetations. Differentiation is difficult at first; the fever suggests an acute eruptive disease or gastro-intestinal or respiratory affection. In infants, the clinical picture may be that of a retropharyngeal abscess; the fever may keep up for several days and frequently recurring attacks may suggest tuberculosis. The peculiar shape and elastic consistency of the indolent tough glands is important for differentiation. Usually the attack runs its course in a few days. In one case otitis media developed. There was no tendency to nephritis in any of his cases. He does not advise active measures in treatment during the attack; the swelling of the glands usually subsides spontaneously. The children are generally of the exudative diathesis type, and it is wise to change the diet and limit the amount of food, hoping thus to influence the constitutional anomaly. It was his impression that considerable benefit followed in his cases, and he urges others to give this dietetic treatment a trial, limiting the children to a pint of milk a day at most and ordering a vegetable diet when this is possible.

119. Permeability of the Meninges.—Weil and Kafka have been testing the permeability of the meninges by determining the presence of antibodies in the cerebrospinal fluid. They tabulate the findings in forty-four cases. Fully 97 per cent. of the twenty-four patients with progressive paralysis gave a positive response while the findings were constantly negative in twenty controls with other nervous affections.

123 *Successful Direct Transfusion of Blood by Suture of Blood-Vessels. (Zur Frage der direkten Bluttransfusion durch Gefässnaht.) H. Flörcken.
124 The Coxa Vara Question. W. Hagen and G. Drehmann.

123. Direct Transfusion of Blood by Suture of Blood-Vessels.—Flörcken applied this measure as a last resort in a case of staphylococcus bacteriemia. The patient was a woman of 24 with no history of hemophilia; during convalescence there was sudden hemorrhage from the nose, gums, rectum and stomach, the catheter brought only pure blood and there were petechiæ at the slightest external irritation. The blood seemed to be of normal constitution but the hemoglobin had dropped to 30 per cent. by the sixth day and the usual measures gave no permanent results. An older step-sister gave the blood for the transfusion; her left radial artery was sutured to the left median vein of the patient, the left hand of the sister lying in the bend of the patient's elbow. The lumina of the two vessels were protected by paraffin from drying and they were sutured together according to Carrel's technic. The difference in the size of the two vessels made the suture difficult but the procedure proved successful. The connection was kept up for half an hour, during which time the patient visibly revived; there were no further hemorrhages and she was soon restored to health.

136 Pathology of Universal Hydrops of the Fetus. R. Teuffel.

125. **The Trendelenburg Position in Obstetrics.**—Bumm calls attention to the advantages of raising the pelvis in doing obstetric operations, especially during extraperitoneal Cesarean section, and for internal version, bringing down the foot with breech presentation, prolapse of the umbilical cord, management of brow and face presentation, etc. By raising the pelvis the heavy uterus slides down out of the way and gives ample space for the obstetrician's hand. The more the presenting part is pressed down into the pelvis, the greater the favorable influence of the Trendelenburg position. In a recent case of transverse presentation, he was able to bring down a foot with ease when the pelvis was raised, the sliding down of the uterus causing a relaxation of the walls which, he is convinced, materially reduced the danger of rupture during the version.

128. **Paroxysmal Tachycardia with Spontaneous Delivery.**—Langes reports a case and cites two others from Zangemeister's experience in which paroxysmal tachycardia was observed in women with previously sound cardiovascular systems. In two cases the anomaly passed without leaving appreciable disturbances but in the other case acute dilatation developed, which must have impaired more or less the integrity of the mitral valve. A sudden increase in the pulse-rate may therefore be observed with normal delivery even with a sound heart, and this possibility should not be forgotten in cases suggesting internal hemorrhage.

129. **Serotherapy of Toxemias of Pregnancy.**—THE JOURNAL, February 4, page 388, mentioned a case of recurring pregnancy herpes which subsided after injection of 10 and 20 c.c. of serum from a healthy pregnant woman near term. Mayer here reports an additional case in which serotherapy was used for urticaria with severe pruritus in a healthy woman at term, and the affection promptly subsided. The pruritus returned a week later as labor commenced but ceased abruptly as delivery was complete. In two other cases of pregnancy toxicosis the serotherapy had a similar promptly beneficial effect, the pruritus ceasing at once after injection of the serum. He suggests that all kinds of pregnancy toxic disturbances, including eclampsia, albuminuria, hyperemesis, tetany and possibly osteomalacia might be benefited by this serotherapy. The aim is to supply substances present in the normal pregnant human organism, the lack of which is causing the trouble; horse serum consequently would not answer the purpose. He used serum exclusively from women giving a negative Wassermann reaction and apparently entirely healthy. [Compare with Abstract 85 above.]

130. **Treatment of Uterine Cancer.**—Theilhaber is convinced that defective nourishment of the mesodermal tissue is an important factor in development and recurrence of cancer. Consequently, retention of the ovaries may aid in preventing recurrence after removal of the uterine cervix by the flux of blood to the region at the menstrual periods. He cites statistics to show that the end-results are more satisfactory with partial operations than is generally conceded. Schröder has 40 per cent. still in good health of ninety-six patients treated by intravaginal or supravaginal amputation of the cancerous uterus from four to eleven years ago. Theilhaber emphasizes the necessity for distinguishing between the origin and the growth of a cancer; when the cancer is once installed, then particularly favorable conditions for nourishment, as in the young, promote the growth of the cancer. But he presents evidence to show that cancer does not start in well-nourished tissues. Another argument in favor of the partial operations is that there is less cicatricial tissue left and thus less predisposition to malignant disease. For these and other reasons cited, he now makes a practice of amputating the cancerous cervix in the vicinity of the internal os uteri. He also makes a point of promoting the circulation in the region afterward by inducing regional hyperemia with superheated air, sitz baths, etc. The patients are all tested for the Wassermann reaction and mercury and iodid given with positive findings.

134. **So-Called Postoperative Pseudomenstruation.**—Neu says that an apparently regular menstrual hemorrhage occurred two or three days after an operation on the uterine adnexa in each of his fifty-four cases of the kind since he has been studying the subject. His conclusion is that it is a true menstrual phenomenon for which the irritation from the operation gave the impulse.

135. **Roentgen Rays in Non-Malignant Gynecologic Disease.**—Gauss thinks that the time has come to cease to regard this method of treatment as still untried and unreliable. The first tentative efforts to utilize the Roentgen rays in gynecology are now long past and the method has reached a stable footing. He has been applying it for over four years and in 200 cases; he here analyzes the remarkably favorable end-results as observed in 100 cases during the last two years during which time the technic has been practically uniform. The report issues from Krönig's clinic at Freiburg, and Krönig's endorsement of the method was mentioned in these columns, Aug. 27, 1910, page 812, and Schindler's endorsement, December 17, page 2187. Gauss here discusses the various groups of cases, going into minute details in order to present the subject in its true light. The younger the patient the longer the course of treatment required. Myomas require about two months in women over 50 and three additional weeks in women under 45, while other hemorrhagic uterine affections require from nine to fifteen weeks before amenorrhea is definitely installed. Recent improvements in technic permit the necessary total dose of radiant units for a myoma to be incorporated in less than a month, the tumor rapidly shriveling under the influence of the rays. He summarizes in two charts the time and dosage required in the two classes of cases.

145 *Connection Between Syphilis and Heart Disease. (Syfilitiske Hjertesygdomme.) V. Bie.

145. **Heart Disease and Syphilis.**—Bie is convinced that the frequency of syphilis as the causal factor of heart disease is underestimated. In his experience he found among eleven tabetic patients that one had well-defined insufficiency of the aortic valves and another the same in a milder form. Among seventeen patients with aneurysm of the aorta he found unmistakable evidences of syphilis in fourteen, that is, in 82 per cent. The Argyll-Robertson sign was positive in five of the sixteen examined and the knee-jerk was absent in three in this group as also in two others. In short, seven of the sixteen patients with aneurysm of the aorta presented unmistakable signs of incipient tabes. Analysis of the hospital records shows, he continues, that the knee-jerk was absent in 27 of 511 patients under treatment in the last two years. In this group of twenty-seven, eight had tabes and three dystrophy of the muscles, alcoholic neuritis or paraplegia. The remaining sixteen patients had either pneumonia or malignant disease of the stomach, with the exception of a child with mitral stenosis and a woman with chlorosis. Examination of the total pneumonia records showed that the knee-jerk was absent or feeble in 49 per cent. of the patients; this demonstrates that pneumonia alone is liable to abolish the knee-jerk. In the twenty-three cases of aortic valvular defect there was a history of acute articular rheumatism in nine, and of tabes in three, while there was a history of syphilis in four others. Only one of the seven patients with aortic insufficiency for which no explanation was evident was of an age to suggest the possibility of syphilis; the others were near or under 20. Similar analysis of the group of eighty-five patients with myocarditic or coronary disturbances showed that eleven were certainly and four probably syphilitic. Among the 187 cases of mitral defects at the hospital in the last ten years, acute rheumatism or chorea was known in the history of 120 of the 160 examined, and scarlet fever, pneumonia or puerperal fever in some of the other cases, but nothing of syphilis except in one case. The average age of the patients with mitral defect was 30, while with syphilitic aortic disease it was 42, for aneurysm of the aorta, 50, and for syphilitic myocardium trouble, 52. There is thus an interval of nearly fifteen years between the clinical development of these affections on a rheumatic and a syphilitic basis. It seems evident that syphilis attacks preferably the aorta and myocardium, while it spares the mitral valve. The connection between tabes dorsalis and heart disease in syphilitics is evident from the aortic disturbances so frequently noted in patients with tabes but still more by the frequency of symptoms of tabes observed in the course of heart or valvular affections, the absence of the pupil reflex in particular. The facts observed suggest, Bie thinks, that the heart affections in question are more closely allied to the parasyphilitic than to other kinds of late syphilitic affections.

NEW AND NONOFFICIAL REMEDIES, 1911

THIS BOOK contains the medicinal substances which, prior to Jan. 1, 1911, have been examined by the Council on Pharmacy and Chemistry of the American Medical Association, which appeared to comply with the rules of the Council and which therefore were accepted for inclusion in the annual "New and Nonofficial Remedies." The acceptance of the articles included in the book has been based in part on evidence supplied by the manufacturer or his agent, and in part on investigation made by or under the direction of the Council. Criticisms and corrections to aid in the annual revision of the matter are requested.

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that so far as known it complies with the rules adopted by the Council.

This book is issued annually. During the year descriptions of further medicinal substances accepted by the Council for inclusion in "New and Nonofficial Remedies" will be published in THE JOURNAL from time to time.

W. A. PUCKNER, Secretary.

OFFICIAL RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY

Introduction.

Object of the Rules.—The following rules have been adopted by the Council with the object of protecting the medical profession and the public against fraud, undesirable secrecy and objectionable advertising in connection with proprietary medicinal articles.

Contents of N. N. R. The "N. N. R." contains a description of such proprietary articles as have not been found to conflict with the rules of the Council; and of such simple non-proprietary and unofficial substances as seem of sufficient importance.

Attitude on Mixtures. Proprietary pharmaceutical mixtures should comply with the rules and will be investigated by the Council. The Council, however, endorses the principle that prescriptions should be written on the basis of the therapeutic effects of the individual ingredients. For this reason, it does not include mixtures in this book unless they present some real advantage. If, however, the physician wishes to prescribe ready-made proprietary mixtures, he will find in the appendix, listed under the name of the manufacturer, those proprietary mixtures which on examination have not been found to conflict with the rules.

Non-proprietary Mixtures. Non-proprietary mixtures share the status of the substances from which they are prepared, and therefore are not contained in the book.

Rules Governing the Admission of Proprietary Articles to the Book, "N. N. R."

Definition of Proprietary Articles.—(The term "proprietary article," in this place shall mean any chemical, drug or similar preparation used in the treatment of disease, if such article is protected against free competition, as to name, product, composition or process of manufacture; by secrecy, patent, copyright, or in any other manner.)

Rule 1.—Composition.—No article will be accepted for inclusion with "New and Nonofficial Remedies" unless its composition be furnished to the Council for publication. For simple substances the scientific name and the chemical formula, rational or structural if known, should be supplied. For mixtures the amount of each active medicinal ingredient in a given quantity of the article must be stated. The general composition of the vehicle, its alcoholic percentage, and the identity of the preservatives, must be furnished.

Rule 2.—Identity.—No article will be accepted unless suitable tests for determining its composition are furnished to the Council. In the case of chemical compounds these shall consist of tests for identity and purity. In the case of mixtures, methods shall be furnished for determining the amount and active strength of the potent ingredients if practicable.

Rule 3.—Direct Advertising.—No article that is advertised to the public will be admitted; but this rule will not apply to disinfectants, advertised for uses other than on the human body, or to non-medicinal food preparations, except when advertised in an objectionable manner.

Rule 4.—Indirect Advertising.—No article will be admitted whose label, package or circular accompanying the package contains the names of diseases, in the treatment of which the article is said to be indicated. The therapeutic indications, properties and doses may be stated. (This rule does not apply to vaccines and antitoxins, or to directions for administering or applying remedies where similar immediate, heroic treatment is indicated.)

Rule 5.—Fraudulent Claims as to Origin.—No article will be admitted or retained concerning which the manufacturer or his agents make false or misleading statements as to source, raw material from which made, or method of collection or preparation. The identity of the actual manufacturer of the article must be furnished.

Rule 6.—Unwarranted Therapeutic Claims.—No article will be admitted or retained concerning which the manufacturer or his agents make unwarranted, exaggerated or misleading statements as to the therapeutic value.

Rule 7.—Poisonous Substances.—The principal label on an article containing "poisonous" or "potent" substances must state plainly the amount of each of such ingredients in a given quantity of the product.

Rule 8.—Objectionable Names.—If the trade name of an article is not sufficiently descriptive of its chemical composition or pharmaceutical character, or is, for any other reason, unsatisfactory or objectionable, the Council reserves the right to include with the trade name a descriptive title in the book. Articles bearing objectionably suggestive names will be refused consideration. Names which suggest diseases, pathologic conditions or therapeutic indications will not be admitted. In the case of pharmaceutical preparations or mixtures the trade name must be so framed as to indicate the most potent ingredients.

Rule 9.—Patented Products and Protected Names.—If the article is patented—either process or product, or both—the number of such patent or patents should be furnished to the Council. Furthermore, if the name of an article is registered, or the label copyrighted, the registration (trade-mark) number and a copy of the protected label should be furnished the Council. In case of registration in foreign countries the name under which the article is registered should be supplied.

Rule 10.—Unscientific and Useless Articles.—No article will be admitted which, because of its unscientific composition, is useless or inimical to the best interests of the public or of the medical profession.

Explanatory Comments on the Rules.

Introduction.—*History, Purpose, and Method.*—The Council on Pharmacy and Chemistry was established in February, 1905, by the American Medical Association, primarily for the purpose of gathering and disseminating such information as would protect the medical profession in the prescribing of proprietary medicinal articles. In pursuance of this object the Council examines the articles on the market as to their compliance with definite rules which are designed to prevent fraud, undesirable secrecy and the abuses which arise from advertising to the laity. Such articles as appear to conform to the rules are admitted and their essential features are described in the annual publication of the Council, the "N. N. R.," if they come within the scope of this book.

Submitted Evidence.—This description is based in part on investigations made by or under the direction of the Council, but in part also on evidence or information supplied by the manufacturer or his agents. Such interested statements are examined critically, and are admitted only if they appear to be in conformity with the evidence. It is, however, manifestly impossible for the Council to investigate the composition of every complex pharmaceutical mixture, or thoroughly to check every therapeutic claim; it can only give an unbiased judgment on the submitted evidence. Criticisms and corrections of the descriptions which may aid in the revision of the matter will be appreciated.

Previous Infringements and Fraud.—The Council judges an article entirely by the facts existing at the time of its admission. Previous infringements of the rules (short of *intentional* fraud) do not prevent the favorable consideration of an article, provided that they have been thoroughly corrected.

Reconsideration.—Infringements after admission, or the discovery that the Council's information was incorrect, will cause the acceptance to be reconsidered.

Acceptance Not an Indorsement.—The Council desires physicians to understand that the admission of an article does not imply a recommendation. It means only that no conflict with the rules has been found by the Council.

The Scope of the "N. N. R." and Appendix.—To aid physicians and manufacturers in deciding what articles come within the scope of this book, or, in other words, to enable physicians to recognize whether an article has been omitted because it does not need admission or because it has been rejected, the Council furnishes the following more detailed definitions:

Official Articles.—The status of the articles which are official in the United States Pharmacopeia or in the National Formulary naturally does not require the approval of the Council. Since authoritative information concerning them is readily obtainable, they have no place in the "N. N. R."

Nomenclature.—To avoid confusion with non-official substances marketed under similar names the Council recommends that they be prescribed by their official Latinized title, followed by the abbreviation, "U. S. P." or "N. F.," thus: Tincturæ Nucis Vomicæ U. S. P. 5 Cc., Elixir Gentianæ N. F. 95 Cc.

Trade Names. Priority. Imitations of Official Articles. "Trade names," protected or otherwise, for these articles will not be recognized by the Council unless they antedate the recognition of the article in the United States Pharmacopeia or National Formulary. Nor will non-essential modifications of official or non-proprietary preparations be recognized. Essential and important modifications, however, will be accepted and will receive individual *mention in the "N. N. R."*

Substances Described in the "N. N. R."—In the body of the book will be described simple proprietary substances and their preparations when these are marketed by the original manufacturer; proprietary mixtures if they have originality or other important qualities which entitle them to such place; and important non-proprietary unofficial articles.

Suffix "N. N. R."—The Council recommends that when these latter are prescribed, they be indicated by the abbreviation, "N. N. R." thus insuring to the prescriber the quality of these articles laid down in the book.

Proprietary Mixtures.—*Definition.*—A mixture will be considered as proprietary, and therefore requiring consideration by the Council and admission to the book or appendix, if it contains any proprietary article; if it is marketed under a name which is in any way protected; or if its manufacturer claims for it any unusual therapeutic qualities.

Where Listed.—All proprietary mixtures which are marketed in conformity with the rules are listed in the appendix of the "N. N. R." under the names of their manufacturers. They are not admitted to the body of the book, save in the exceptional cases cited in the preceding paragraph.

Non-Proprietary Mixtures of Official Substances.—Since the ingredients of such mixtures do not require the approval of the Council, and since the mixtures are not open to the proprietary abuses which called for the work of the Council, it is not necessary that they should be investigated and approved by the Council. The physician should judge whether such mixtures should be directed to be prepared by the pharmacist, or whether he is justified in ordering a ready-made preparation. If he decides to use a ready-made non-proprietary preparation he must judge for himself if it is marketed in accordance with the rules.

Trade Names.—It should also be remembered that the application of trade names to any substance makes it proprietary.

Objectionable Trade Names for Official Substances.—The application of "trade names" to official or established non-proprietary products tends to confusion and fosters many abuses. It can only be condoned if the "trade name" possesses priority as previously defined. Such trade names will therefore not be admitted by the Council except in those few cases in which the trade name has already come into extensive use.

Use of Firm Names.—The protection of the manufacturers can be amply secured by appending the firm or "brand" name to the official name, and to this there can be no objection. Appended names or initials of manufacturers as in Mistura Rhei et Sodæ. X. Y. & Co.; Mixture of Rhubarb and Soda, "Jones;" Pills of Aloes and Iron, "Smith brand," are considered non-proprietary.

Generic Names.—Protected generic brand names shall not be regarded as proprietary. However, the preparation "Adrenalin suppositories" is proprietary because the name adrenal itself is protected.

Unessential Modifications of Official Substances.—*Imitations.*—The subterfuge for obtaining proprietary rights over an official or established non-proprietary product, by introducing unessential modifications, also tends to confusion and abuses, and such articles will not be admitted by the Council. Essential and important modifications, however, will receive recognition. (The Council interprets the term "established non-proprietary product" to apply to a preparation or any formula which has been published through any recognized or reasonably accessible channel of publication, prior to its appropriation or modification by a manufacturer.)

Explanatory Comments on the Rules Governing the Admission of Proprietary Articles.

Rule 1.—Composition.—*Secrecy Objectionable.*—It is not only the right but the duty of the physician to know the essential composition of what he prescribes; the Council cannot compromise on this proposition.

Vehicles and Preservatives.—In the case of mixtures not only the potent ingredient, but also the general character of vehicle, the presence of alcohol, and the identity of preservatives, or of any other substance, whether added or present as an impurity, must be stated, if these can under any circumstances affect the action of the article. This generally does not mean the publication of such trade secrets as flavors or the details of the working formula.

Trade Secrets.—Furthermore, trade secrets will not be received as confidential by the Council, since it accepts information only with the distinct understanding that this may be freely published, at its discretion.

Inspection of Factories.—Nor does the Council accept invitations to inspect factories; its concern is with the finished products.

On the other hand, the Council requires that the information be complete and accurate as to the medicinal ingredients.

Unofficial Constituents.—Unofficial constituents of proprietary mixtures must be submitted by the manufacturer in the regular way and must be approved by the Council before the preparations containing them can be admitted.

Fraud.—When it appears that a manufacturer has made a *deliberately* false statement concerning his product he is asked to furnish an explanation: and if this is not satisfactory the product will not be admitted, even if the false statement is subsequently corrected or omitted.

Testimonials.—This applies not only to statements made to the Council, but also to statements furnished to physicians by the manufacturer or his agents, even when these statements are in the guise of testimonials.

Rule 2.—Identity.—In order to avoid errors in the case of chemical compounds, and to guard against adulterations, lack of potency or strength and the mistaking of one chemical for another, it is necessary to have at hand suitable tests.

Tests, etc.—If these facts have appeared in the literature, or in standard text-books, reference to them will be sufficient; but with new chemicals, especially synthetics, the manufacturer or his representatives will be required to supply such tests for publication, in order that an intelligent opinion of these products may be assured.

Physiologic Standardization.—In cases in which chemical methods of identification are unknown or unreliable, physiologic standardization should be employed. The Council considers the phrase "physiologically standardized" or "assayed" as misleading unless the standard and method are published in sufficient detail to permit of their control by independent investigators.

It is evident that when no standard is published, it is impossible to know whether the quality is high or low, and the conscientious manufacturer who sets for himself a high standard is placed on a level with the dishonest or careless one who adopts a low standard. Again, if the process is not published, it is impossible to learn without actual trial the relative value of one preparation as compared with that of another manufacturer or to confirm or disprove the statements of the manufacturer as to the quality of his product.

Rule 3.—Direct Advertising. — *Lay Advertising.* — The impossibility of controlling the irresponsible claims which are usually made in advertisements to the public, the well-known dangers of suggesting by descriptions of symptoms to the minds of the people that they are suffering from the many diseases described, the dangers of an unconscious and innocent formation of a drug habit, and the evils of harmful self-medication, including the dangers of the spread of many infectious and contagious diseases when hidden from the physician, and similar well-known considerations, are the reasons for discouraging, in the interest, and for the safety, of the public, this reprehensible form of exploitation.

Exceptions.—In the case of subjects on which the public should be instructed, as the use of disinfectants and foods, such advertisements, if not in objectionable forms, are considered admissible.

Foods.—We may divide the foods into three groups. The first group contains the ordinary foods, including the well-known breakfast foods. These do not come under the supervision of the Council in any way. The second group includes medicinal foods proper, such as predigested foods, which have a relatively low food value and which are characterized by a high alcohol or preservative content, and which frequently contain strictly medicinal substances, or food substances for which distinct therapeutic properties are claimed. These products should be used only on the advice of the physician, and the advertisements should be restricted as in the case of ordinary medicines. The third group includes a large and important class of manufactured products, such as invalid and infant foods, which in a sense stand between the first and second groups. The public has the same interest in these foods that the physician has, and usually has full information concerning them. While the primary recommendation of these articles should naturally come from the physician, it cannot be expected that their continued use should depend on repeated prescriptions. Information concerning this group of foods would come naturally and properly from a physician, and the collection and dissemination of this information may very properly be included in the work of this Council. As the use of products in this class is an extended one, it is not proper to limit their advertising to medical journals, but the advertising should be permitted in the lay press so long as it is conducted in a manner compatible with the rules of the Council.

Rule 4.—INDIRECT ADVERTISING.—It should be remembered that the sole intent of this rule is to protect the physician, so that in prescribing a proprietary medicine he need not unconsciously become an advertising agent of proprietors. The rule imposes no restriction on the legitimate methods of bringing a remedy to the attention of the profession, such as advertising in medical journals, circulars and other printed matter distributed solely to physicians. The rule applies only to the package as it may reach the patient.

Naming Diseases on Label.—The naming of diseases on the label or package is not necessary, as is shown by the very large number of proprietary products which have been successfully introduced without resorting to this expedient. This method of popularizing a proprietary remedy with the laity is most objectionable, and should not be tolerated in any form.

Therapeutically Suggestive Names.—The Council considers therapeutically suggestive names (see Rule 8) as an unworthy expedient to the same end. It would prefer to have therapeutic indications omitted from the label and package, but does not insist on this point, because these are useful in some exceptional cases.

Permanently Affixed Names.—It will be considered an infringement of the rule when an article is marketed in bottles which have the name of the article blown into the glass, or if otherwise the name or initials or other distinctive mark of the article are permanently stamped on the container, on the article itself, or are contained on the stoppers or seals. Articles which are marketed in any of these ways are not admitted. Readily removable labels are not objectionable.

Use of Articles for Advertising.—The Council does not countenance the use of an admitted article for advertising other articles which have not been admitted by the Council.

Rule 5.—FRAUDULENT CLAIMS AS TO ORIGIN.—No false or misleading statement in regard to an article can be permitted concerning the source or material from which it is made, or the persons by whom it is made. Some glaring frauds of this nature have been perpetrated in the past, and this rule is intended to prevent such imposition.

Actual Manufacturer.—The identity of the actual manufacturer of an article should be known, since the manufacturer is in part responsible for the quality of the product. No good reason can exist for concealing the identity of the manufacturer of a legitimate article; such concealment must be considered evidence of the doubtful character of a product or its method of exploitation.

Rule 6.—UNWARRANTED CLAIMS AS TO THERAPEUTIC VALUE. —This rule is intended to restrict the direct and indirect claims of the manufacturers or agents as to the therapeutic superiority of their products, to what is compatible with ascertained facts: Manufacturers will be held responsible for all statements referring to their products, made in their advertising literature, whether they occur as original statements or as quotations. The Council aims to be quite liberal in the application of this rule. There are honest differences of opinion as to many therapeutic questions.

Permissible Optimism.—It is natural that a manufacturer should be rather partial toward his own product, and, since every one should be cautious in accepting such biased claims, a moderate degree of emphasis may not be objectionable. The Council, therefore, does not assume to censor any reasonable statements, especially when such statements are confirmed by responsible clinicians.

Exaggerated Claims.—Claims are often made, however, which are incompatible with common experience and which sometimes defy the laws of Nature. Claims which seem highly improbable will not be admitted by the Council unless the manufacturer supports them by evidence acceptable to the Council. In doubtful cases the Council acts on these questions under the advice, and with the cooperation of its staff of clinical consultants.

Rule 7.—POISONOUS SUBSTANCES.—For the information of the pharmacist or dispenser, and to enable him to safeguard the interests of the patient and the physician, all articles containing such potent agents as the poisonous alkaloids and other organic substances and the salts of some of the metals, should have the exact amount of these ingredients which is contained in the average adult dose stated on the label.

Rule 8.—OBJECTIONABLE NAMES.—Many of the abuses connected with proprietary medicines are intimately associated with the more or less arbitrarily selected or "coined," usually protected, names.

Scientific Names.—In the interest of those physicians who would prefer to employ a more rational nomenclature the Council advises the use of scientific names by the manufacturers, at least as synonyms. In view of the existing trade conditions, however, it does not insist on this except in such specific cases as explained below in which experience has shown the necessity of restrictions.

Pharmaceutical Preparations and Mixtures.—Since these, with rare exceptions, are not original in composition, there is no sufficient reason why they should be endowed with arbitrary names; on the contrary, it is important that the prescribing physician should be constantly reminded of the potent ingredients on which the actions of such preparations are based. It is particularly important that actively poisonous or habit-forming drugs be not disguised under an innocently worded title.

Coined Names Where Permitted.—The Council recognizes, on the other hand, the right of discoverers of new synthetic products or active principles to name their discovery, and interposes no objection to arbitrary names for such products, so long as such names do not tend to advertise the product to the laity, as specified under Rule 8. It is desirable, however, that the coined names should indicate the chemical composition of the article. With synthetic chemicals the true chemical name should be stated, at least in addition to the trade name. If an article conflicts only with Rule 8 it may be admitted as soon as the manufacturer substitutes a name which the Council considers satisfactory.

Rule 9.—PATENTS, TRADE-MARKS, COPYRIGHTS, ETC.—This information is desirable in determining the legal status of these articles and will permit their ready recognition in current publications.

Rule 10.—UNSCIENTIFIC AND USELESS ARTICLES.—The Council has been justly criticized because its rules failed to exclude certain unscientific mixtures whether of well-known or obscure substances. The use of articles which are unessential modifications of official or established non-proprietary articles is unscientific and serves no useful purpose. The Council will not admit products which are scientifically unsound and which, therefore, must be considered useless or inimical to the best interest of the medical profession and the public. This class includes mixtures containing an excessive number of ingredients; those which contain substances of no probable therapeutic assistance to each other; those of no therapeutic value. The combination of two or more remedies in a mixture must be considered contrary to scientific medicine unless a distinct reason exists for such combination. This holds especially for ready-prepared mixtures, and these shall be deemed in conflict with Rule 10 unless the manufacturer presents satisfactory evidence for the value of his combination.

NEW AND NONOFFICIAL REMEDIES

ACETOZONE.—Acetozone is a mixture of equal parts of acetyl-benzoyl peroxide and an inert absorbent powder.

Acetyl-benzoyl peroxide, $C_6H_5CO.O.O.COCH_3 = C_9H_8O_4$, corresponds to hydrogen peroxide, H_2O_2, in which the two hydrogen atoms have been replaced by the radicles of acetic acid (the acetyl group) and of benzoic acid (the benzoyl group).

Acetyl-benzoyl peroxide occurs in white, shining crystals, melting at 36.6° C. (98° F.). When heated it slowly decomposes and volatilizes. Water at 25° C. (77° F.) dissolves one part in 1.560 or 0.639 Gm. in 1,000 Cc. It is soluble in oils to the extent of about three per cent., slightly soluble in alcohol, and fairly so in ether, chloroform, and carbon tetra-chloride, though all solvents slowly decompose it with the exception of neutral petroleum oils.

In the presence of water it undergoes hydrolysis and slowly decomposes. This change, however, does not take place with sufficient rapidity to prevent its use in aqueous solution; in fact such hydrolysis is necessary to develop its full germicidal activity. On account of its ready decomposition, acetozone should be kept in a dry place.

For various reasons it has been found necessary to add an inert absorbent powder. As found in the market, acetozone is of a grayish white color, possessing the properties of the crystalline substance, with the exception that the absorbent powder employed is insoluble.

Actions and Uses.—Acetylbenzoyl peroxide belongs to a class of compounds known as the organic peroxides in which an excess of oxygen has been combined in such a way that it is somewhat slowly given off in a nascent condition. On contact with water it hydrolyzes, forming benzo-peracid and aceto-peracid, which exert marked oxidizing and germicidal action. In consequence of this change, these compounds are thought to be particularly adapted for internal administration.

It is said to be useful as an antiseptic in ophthalmic, aural and nasal practice, and to give good results by acting as an intestinal antiseptic when given internally, especially in typhoid fever.

Dosage.—Acetozone is generally employed in aqueous solution prepared as follows: Add acetozone to warm water in the proportion of 1 Gm. to 1,000 Cc. (15 grains to the quart), shake vigorously for five minutes, and allow to stand for about two hours. Decant the liquor as required. This solution may be drunk *ad libitum*, two quarts or more being taken by an adult in twenty-four hours. Acetozone is also used in oily solution as an inhalant.

Manufactured by Parke, Davis & Co., Detroit, Mich. U. S. patents No. 710,005 (Sept. 30, 1902; expires 1919) and No. 717,016 (Dec. 30, 1902; expires 1919). U. S. trademark.

Acetozone Inhalant.—Each 100 Gm. contain acetozone 1.0 Gm.; chloretone (chlorbutanol), 0.5 Gm.; refined liquid petroleum, 98.5 Gm.

ACETPHENETIDIN

ACETPHENETIDIN.—Acetphenetidin is official in the United States Pharmacopeia. For description see the pharmacopeia or the Physician's Manual of the Pharmacopeia and the National Formulary.

Actions and Uses.—This is one of a large group of derivatives or chemical relatives of aniline (amino-benzene). The members of this group have similar properties and are more or less active according as they undergo decomposition in the system so as to yield either para-amino-phenol or acetyl-amino-phenol. They have a more or less pronounced action on the blood by which they produce hemolysis and destruction of the red blood corpuscles. They also act as heart depressants.

Acetphenetidin and its congeners are antipyretics and analgesics. They are extensively employed for the relief of pain. For this purpose they should be used with caution in consideration of their poisonous properties.

They have also been considerably employed for the reduction of temperature in fever. Every newly discovered product related to acet-phenetidin has been heralded as a "safe" antipyretic and free from poisonous effects on the blood and heart. Invariably extended clinical experience has shown that all these preparations are to a greater or less degree hemolytic and depressing to the circulation. Hence their employment in the infectious fevers should be most cautious.

PHENACETIN.—Phenacetin is a name applied to Acetphenetidinum, U. S. P.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co. Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 400,086 (expired); U. S. trademark Nos. 16,392 and 18,637.

AGAR-AGAR.—Agar-agar (Agar-agar, Pharm. Française, 1908) is a substance extracted in the East Indies from various sea weeds.

This substance seems to come principally from Eucheuma gelatinum, E. spinosum (Linné) J. Agardh., Gelidium corneum (Hudson) Lam., G. cartilagineum Gaill., Gloiopeltis tenax (Turner) J. Agardh.

Agar-agar is extracted by hot water and dried for commercial purposes in the form of bundles of shreds, or powder form. It is odorless and insipid, insoluble in cold water but soluble in hot water. A solution containing 1.5 per cent. gives quite a stiff jelly on cooling.

Agar-agar consists practically of gelose, which dissolves in 500 parts of water and is precipitated in an impure form by alcohol. Gelose is a carbohydrate which is converted into galactose on boiling with dilute sulphuric acid. On drying at 100° C. agar-agar loses about 20 per cent. of water. 100 parts of dry substance furnish about 4 parts of ash, which, when treated with hydrochloric acid and examined with the microscope, shows the presence of diatoms, the most characteristic of which are Arachnoidiscus—Ehrenbergii Baill. and several Grammatophora and Cocconeis. An aqueous solution of agar-agar gives no precipitate with solution of tannic acid (absence of gelatin), and no blue color with solution of iodin (absence of starch).

Actions and Uses.—Agar-agar absorbs water in the stomach and intestines and forms a jelly, which being indigestible increases the bulk of the feces.

It is employed as a demulcent and for the treatment of constipation.

Dosage.—From 5 to 15 Gm. (75 to 240 grains). Agar-agar is administered in substance, coarsely comminuted and mixed with food.

AGARIC ACID.—Acidum Agaricum.—Acidum Agaricinicum (Pharm. Helvetica, edit. 4.) Agaricinum[1] (Pharm. Danica, edit. 1907). A tribasic acid $C_{19}H_{36}OH\ (COOH)_3 + 1\frac{1}{2}H_2O$, derived from Polyporus officinalis, Fries (Order Hymenomycetes; fam. Polyporeæ) a fungus growing on the European Larch and other species of larch.

Agaric acid occurs as an odorless, tasteless, glistening micro-crystalline powder, which melts at 141.5-142° C. (286.5-287.5° F.). When heated to a high temperature it is volatilized in the form of a white pungent vapor.

Agaric acid is slightly soluble in cold water; when heated with 50-100 parts of water, it becomes gelatinous and finally dissolves to a weakly acid solution, which possesses the characteristic property of foaming strongly when shaken. The addition of acids to hot aqueous solutions of agaric acid causes white flocculent precipitate, but a tannic acid solution (1:100) produces neither coloration nor turbidity. With alkalies agaric acid forms water soluble salts.

Agaric acid is slightly soluble in ether, chloroform, carbon-disulphide and in 130 parts 90 per cent. alcohol. It is soluble in hot acetic acid, acetic ether, oil of turpentine and in about 10 parts of alcohol.

If to a mixture of about 0.2 Gm. of agaric acid with 3 Cc. of water 2 drops of alcoholic alpha-naphthol solution (1:8) are added and then gradually 5 Cc. of concentrated sulphuric acid added the mixture should not take on a marked blue-violet color.

If 0.10 Gm. agaric acid be boiled with 10 Cc. dilute sulphuric acid a turbid solution results, from which on standing on a water bath, oily drops separate, and they crystallize on cooling.

0.1 Gm. agaric acid upon ignition should leave no weighable residue.

Action and Uses.—Agaric acid is a local irritant and in large doses produces vomiting and purging, and death through central paralysis. It paralyzes the peripheral nerves of the sweat glands, arresting the secretion of sweat. It is used to arrest colliquative sweats. The experience of most clinicians is favorable, but some report that they were unable to obtain any favorable effects. The action appears in a few hours and is not lasting. Agaric acid is one-twentieth as active as atropine and does not influence other secretions.

---

[1] The substance commonly sold as agaricin is an impure alcoholic extract

Dosage.—The maximal single dose of agaric acid should not exceed 0.03 Gm. (½ grain) and the total daily dose should not exceed 0.10 Gm. (1½ grains) (Pharm. Helv.). Owing to its irritant action it cannot be given hypodermically.

ALBARGIN.—Gelatosesilver.—Albargin is a compound of silver nitrate with gelatose, containing from 13 to 15 per cent. of silver.

It is prepared by adding silver nitrate to a solution of gelatose in water, evaporating the solution or precipitating the compound by the addition of ether or alcohol. It is a coarse, yellow, shining powder, very easily soluble in water, forming neutral solutions. The presence of gelatose, silver and a nitrate can be shown by appropriate tests. It is incompatible with tannin and chlorides.

Actions, Uses and Dosage.—Albargin is used as a substitute for silver nitrate.

Manufactured by Farbwerke, vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York).

Albargin Tablets. Each tablet contains albargin 0.2 gm. (3 grains).

ALPHOZONE.—Succinic Dioxide.—Succinic Peroxide, Disuccinyl Peroxide.—Alphozone, $(COOH.CH_2.CH_2.CO)_2O_2 = C_8H_{10}O_8$, is succinylic acid peroxide, corresponding to hydrogen peroxide, H_2O_2, in which the hydrogen has been replaced by two succinic acid groups; each succinic acid radicle still retaining one of its acid-hydrogen atoms.

It is prepared by the interaction of a strong solution of hydrogen dioxide with succinic anhydride, resulting first in the formation of succinic peracid, $COOH.CH_2.CH_2.COOOH$, which reacts with one molecule of succinic anhydride to form succinic peroxide.

It is a fluffy, white, crystalline powder, the crystals being small irregular plates. It dissolves in 30 parts of water at ordinary temperature. It is moderately soluble in alcohol, acetone, and ethyl acetate, sparingly soluble in ether, insoluble in benzene, chloroform and ligroin. Odorless or nearly so; softens at 115° C. (239° F.) and melts at 127° C. (262° F.) with decomposition. When brought into a flame it explodes, but it does not explode on percussion or friction. It deteriorates slightly on continued exposure to air, but if kept tightly stoppered and in a dark place it remains unchanged indefinitely.

It is a powerful oxidizing agent, liberating iodine from potassium iodide. It can be identified by its physical properties and its powerful oxidizing action. To test its strength add 2 Gm. of potassium iodide to 1 Gm. of alphozone dissolved in 60 Cc. of distilled water. To this slowly add decinormal solution of sodium thiosulphate with constant agitation until the red brown color of the iodine is just discharged. Each cubic centimeter of sodium thiosulphate solution is equivalent to 0.0117 Gm. of alphozone; 1 Gm. of pure alphozone is equivalent to 85.41 Cc. decinormal sodium thiosulphate solution.

Actions and Uses.—Alphozone belongs to the class of organic peroxides, and by virtue of its oxidizing power is germicide and antiseptic. Alphozone also possesses deodorant and bleaching properties. The fact that it does not effervesce with pus nor in contact with the living tissues is claimed as an advantage over hydrogen dioxide.

Alphozone is employed both externally and internally. It is said to be useful for disinfecting the hands and such instruments as are not attacked by oxidizing agents. It is used for the disinfection of the field of operation and has been employed for its germicidal effect with asserted good results in local infections in which the substance can be brought in contact with the diseased surface, such as ulcers, abscesses, inflammation of mucous membranes, and infectious skin diseases. Internally it has been used in typhoid fever and as an intestinal antiseptic.

Dosage.—Alphozone is employed in solutions containing 1 part per 1,000 for general external use. As a nasal douche a proportion of 1 to 3,000 is often preferred.

Manufactured by F. Stearns & Co., Detroit, Mich. U. S. patents Nos. 768,561 and 768,563 (Aug. 23, 1904; expires 1921). U. S. trademark No. 41,981.

Alphozone Tablets, 1 grain. Each tablet contains alphozone 0.065 gm. (1 grain). One tablet to 60 Cc. (2 fluidounces) of water gives a solution of 1 to 1,000.

ALUMNOL—Alumini Naphtholsulphonas.—Aluminum Betanaphthol-Disulphonate.—Alumnol, $Al_2(C_{10}H_5.OH.(SO_3)_2)_3 = Al_2C_{30}H_{18}O_{21}S_6$, is aluminum betanaphthol-disulphonate, the aluminum salt of betanaphthol-disulphonic acid.

It is prepared by mixing solutions of barium naphthol-disulphonate and aluminum sulphate in molecular proportions, filtering off the barium sulphate, and evaporating the filtrate to dryness.

It forms a fine, nearly white, non-hygroscopic powder, soluble in 1.5 parts of water, forming a faintly acid and slightly fluorescent solution.

It is also easily soluble in glycerin, but sparingly soluble in alcohol and insoluble in either. When dried it loses about 9 per cent. of water, and when exposed to the air it is darkened in consequence of its reducing properties. It is precipitated from solution by albuminous and gelatinous bodies, but these precipitates are redissolved in excess of the latter bodies.

The aqueous solution (1-10) should be clear, and after acidulation with hydrochloric acid should become at most only slightly turbid, and only just tinted bluish by potassium ferrocyanide; nor should precipitates be produced in it on the addition of diluted sulphuric acid or solution of ammonium oxalate. The dried compound should yield 12.7 per cent. of ash (alumina) on incineration.

It should not be exposed to the air, and is incompatible with salts of silver, or other reducible salts.

Actions and Uses.—It is an astringent and mild antiseptic. It is claimed that it can be used as a mild astringent, an irritant or a caustic, according to the strength of the solution, and it is asserted that it exerts a peculiarly destructive action on gonococci. It has been recommended for a variety of affections in which a caustic, astringent or antiseptic is indicated. It has been particularly recommended for gonorrhea in females, especially when affecting the endometrium.

Dosage.—As a surgical antiseptic, in 0.5 to 3 per cent. solutions; in gynecology, in 2 to 5 per cent. solutions; in otology and laryngology, either as a powder or in ¼ to 1 per cent. solution as douches, washes or gargles; as cautery, in 10 to 20 per cent. solution.

Manufactured by Farbwerke, vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York). German patent No. 74,209.

ALYPIN.—Alypin is 2-benzoxy-2-dimethyl-amino-methyl-1-dimethyl-amino-butane hydrochloride, $CH_3.CH_2.C(C_6H_5COO)(CH_2N(CH_3)_2).CH_2N(CH_3)_2.HCl = C_{16}H_{26}O_2N_2.HCl$. It is closely related to Stovaine (which see).

By the action of dichloracetone, $CH_2Cl.CO.CH_2Cl$, on ethylmagnesium bromide dissolved in ether and decomposition by water of the magnesium compound formed, ethyl-dichlorhydrin, $CH_2Cl.C(C_2H_5)(OH).CH_2Cl$, is obtained. From this, by the action of dimethylamine, ethyl-tetramethyl-diamino-propanol is produced. This product is treated with benzoyl chloride and the benzoyl-ethyl-tetramethyl-diamino-propanol neutralized with hydrochloric acid to form the chloride.

Alypin is a white, crystalline powder, melting at 169° C. (336.2° F.), hygroscopic and extremely soluble in water. Its solutions are neutral and are not rendered turbid on addition of sodium bicarbonate in moderate quantities, and may be sterilized by boiling for a period not exceeding five minutes, without decomposition. It is easily soluble in alcohol. It has a markedly bitter taste.

It should be protected from the air in well-stoppered containers. Two and four per cent. solutions are quite stable, but weaker solutions are likely to become mouldy.

Addition of potassium iodide test solution to the aqueous solution (1-100) produces a white precipitate; potassium dichromate test solution produces a yellow crystalline precipitate soluble in hydrochloric acid; potassium permanganate test solution produces a violet crystalline precipitate, which turns brown on standing. If 0.1 Gm. Alypin be mixed with 1 Cc. sulphuric acid and warmed to 100° C. (212° F.) for five minutes and then 2 Cc. water carefully added, the odor of benzoic-ethyl-ester is developed; on cooling crystals separate out, which are dissolved on adding 2 Cc. alcohol. If Alypin is dried at 100° C. (212° F.) the loss should not exceed 1.5 per cent.

Actions and Uses.—It is a local anesthetic, claimed to be equal to cocaine, but not a mydriatic; it is said not to produce disturbance of accommodation and to be less toxic than cocaine.

Dosage.—Externally in the form of a 10 per cent. solution hypodermically in 1 to 4 per cent. solutions; for the eye in 1 to 2 per cent. solutions. As much as 5 Cc. of a 3 per cent. solution was well tolerated in one case.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 808,748 (Jan. 2, 1906; expires 1923). U. S. trademark No. 44,608

Alypin Tablets, 3 1/3 grains. Each tablet contains 0.22 Gm. (3⅓ grains) of alypin.

Alypin Tablets, 1 1/8 grains. Each tablet contains 0.073 Gm. (1⅛ grains) of alypin.

Alypin Tablets, 3/4 grain. Each tablet contains 0.048 Gm. (¾ grain) of alypin.

Alypin Tablets, 1/3 grain. Each tablet contains 0.022 Gm. (⅓ grain) of alypin.

AMMONIUM HYPOPHOSPHITE—Ammonii Hypophosphis.—Ammonium hypophosphite, $NH_4H_2PO_2$, is the ammonium salt of hypophosphorous acid.

Ammonium hypophosphite may be prepared by double decomposition between aqueous solutions of barium hypophosphite and ammonium sulphate. The liquid filtered from the precipitate is evaporated to dryness and the ammonium hypophosphite extracted from the residue with hot alcohol.

Ammonium hypophosphite occurs in irregular hexagonal plates which melt without decomposition and at a higher temperature give off water and spontaneously inflammable hydrogen phosphide. According to H. Rose, ammonia, NH_3 escapes first. The compound is less soluble in water than the potassium salt, but is very soluble in absolute alcohol.

The aqueous solution should be neutral or slightly acid to litmus paper, and on gently heating with potassium hydroxide test solution evolves ammonia. The diluted aqueous solution slightly acidulated with dilated sulphuric acid, yields, with silver nitrate test solution, a brown precipitate, which rapidly turns black, owing to the separation of metallic silver. With copper sulphate test solution, after addition of dilute acid and on gentle heating, a reddish brown precipitate is formed. When the aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is added, drop by drop, to an excess of mercuric chloride test solution, a white precipitate of mercurious chloride is formed. On further addition of the hypophosphite solution in excess, the precipitate becomes gray from reduction to metallic mercury.

The solution in water should give not more than a faint turbidity on the addition of barium chloride test solution nor on the addition of diluted sulphuric acid. A solution of 1 Gm. ammonium, hypophosphite in 10 Cc. water should not be alkaline toward phenolphthalein test solution; to render this solution alkaline should not require more than 0.4 Cc. normal potassium hydroxide. The aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, should not respond to the U. S. P. Time-limit Test for heavy metals. If 5 Cc. of the aqueous solution of the salt (1 in 10) be measured into a beaker containing 3 Cc. of nitric acid, diluted with about 10 Cc. of water and evaporated to dryness on a water bath, the residue should not respond to the U. S. P. Modified Gutzeit's Test for arsenic.

Action and Uses.—Ammonium hypophosphite exhibits the actions of its constituents. There are differences of opinion as to whether these constituents have action other than that on the digestive tract. It is used as a stimulating expectorant and "alterative," in diseases of the respiratory mucosæ, particularly in the later stages of acute bronchitis and laryngitis, and in chronic catarrhal conditions.

Dosage.—0.13 Gm. (2 grains) every 2 or 3 hours.

Proprietary Preparation:

GARDNER'S SYRUP OF CHEMICALLY PURE HYPOPHOSPHITE OF AMMONIUM.—Syrupus Ammonii Hypophosphitis (Gardner).—A syrup containing 3.33 Gm. ammonium hypophosphite in each 100 Cc. (16 grains in each fluidounce).

Action, Uses and Dosage.—See ammonium hypophosphite.

Manufactured by R. W. Gardner, New York City.

AMYL VALERATE — Amylis valeras. — Amyl valerate, $CH_3.CH(CH_3).CH_2.COO(CH_2.CH(CH_3).CH_2.CH_2) = C_{10}H_{20}O_2$, is the iso-valeric acid ester of iso-amyl alcohol.

Amyl valerate is obtained by separating (by distillation) the ester which is formed when valeric acid or solution of a valerate is added to a mixture of iso-amyl alcohol and sulphuric acid and the distillate obtained, washed, dried and redistilled.

Amyl valerate is a colorless liquid, having when dilute an odor of apples. It is insoluble in water, soluble in alcohol, ether and chloroform. It boils at 188-190° C. (370.4-374° F.). Its specific gravity is .858 at 15° C.

Action and Uses.—Amyl valerate has been employed in the treatment of gallstone colic. Its employment in renal colic is not satisfactory.

Dosage.—To relieve biliary colic, 0.2 to 0.04 Cc. (3 to 6 minims) in capsules every half hour; or 1 Cc. (15 minims) in capsules, three times daily.

ANTHRASOL—Colorless Coal Tar.—Anthrasol is coal tar, freed from pitch, pyridin bases and coloring matter, and mixed with juniper tar.

Coal tar is freed from bases, such as pyridin and chinolin by treatment with acids and from pitch by distillation. The distillate, containing the hydrocarbons and phenols of tar is purified to remove constituents causing discoloration. To prevent separation of solid constituents juniper tar is added, and oil of peppermint to correct the odor. It is a thin, mobile, light-yellow oil which does not stain either skin or linen.

Actions and Uses.—Antrasol is antiseptic, parasiticide, keratoplastic, anti-pruriginous; like ordinary tar, it allays irritation of the skin, but is claimed not to obstruct the follicles nor to favor the development of acne.

It is said to be useful in chronic or subacute skin diseases, various forms of eczema, especially for after-treatment, and for all pruriginous affections; in diseases of the hair, as a restorative and for the removal of dandruff.

Dosage.—Locally in the form of a 5 to 10 per cent. petrolatum ointment in eczema; 10 per cent. ointment with glycerite of starch and 10 per cent. of wool fat (adeps lanæ) in pruritus; 20 to 30 per cent. ointment or paste, in lichen; in combination with sulphur and soft soap, in parasitic *skin affections.*

Manufactured by Knoll & Co., Ludwigshafen a. Rh., Germany, and New York. U. S. trademark No. 40,634.

ANTIFORMIN. Antiformin is a strongly alkaline solution of sodium hypochlorite. In each 100 c.c. it contains approximately sodium hypochlorite equivalent to 5.68 gm. available chlorine, sodium hydroxide 7.8 gm., and sodium carbonate 0.32 gm.

According to the patent specification chlorinated lime is dissolved in water at the temperature of 35° C. To this a solution of sodium carbonate is added. After standing the supernatant liquid is decanted and to this sodium hydroxide is added.

Antiformin is a yellowish, clear liquid having the peculiar odor characteristic of hypochlorites.

The per cent. of available chlorine, of alkali hydroxide and carbonate may be determined by the methods described in the Reports of the Chemical Laboratory of the American Medical Association, 1911.

Actions and Uses.—Antiformin rapidly dissolves the bodies of bacteria with the exception of acid-fast organisms like the tubercle bacillus, on which it has no solvent action and which resists its germicidal action to a great extent. It dissolves other organic matters, such as those contained in sputum and feces. It exerts a strong oxidizing action and is disinfectant, antiseptic and deodorizing. It is said to be more than three times as active in germicidal action as phenol.

Based upon its property of dissolving most bacteria and the insoluble constituents of the sputum, Antiformin is employed in testing for tubercle bacilli. It is said to be useful for the sterilization of the surgeon's hands, of instruments and of wounds and for general purposes of disinfection. It is also said to be useful in certain skin diseases.

Dosage.—Externally in from 2 to 10 per cent. solution. In from 4 to 1,000 solution as a spray. As a disinfectant 5 per cent. solutions are used. For the demonstration of tubercle bacilli 15 per cent. solutions are suitable.

Manufactured by the American Antiformin Co., New York. U. S. patent No. 691,671 (Jan. 21, 1902; expires 1919). A process for Cleaning Beer Vats and Pipes, said process consisting according to the patent specifications "in subjecting the walls of said vats or pipes to the action of a solution composed of about 1 part of alkaline hypochlorite with about a half to one part of alkaline hydrate, substantially as specified." U. S. trademark No. 61,693.

ANTIPYRINE SALTS

Antipyrine, phenyldimethylpyrazolon, is a weak base which unites with acids to form unstable salts that hydrolyze readily when dissolved in water separating into their components. The therapeutic activity of these compounds represents a combination of the actions of the acid and the base.

ANTIPYRINE SALICYLATE—Antipyrinæ Salicylas.—Antipyrine salicylate, $C_{11}H_{12}N_2O.C_6H_4OH.COOH = C_{18}H_{18}N_2O_4$, is a weak chemical combination of antipyrine and salicylic acid.

It is prepared by heating antipyrine and salicylic acid, in molecular proportions, on the water bath, allowing the oily product to congeal by cooling, and crystallizing it from alcohol.

It occurs as a white, coarsely, crystalline powder, or in hexagonal tabular crystals, melting at 91° to 92° C. (195.8° to 197.6° F.); odorless, slightly sweet; soluble in 200 parts of cold and 40 parts of boiling water; readily soluble in alcohol, less readily in ether. It is decomposed by acids with the elimination of salicylic acid, and by alkalies with the elimination of antipyrine.

Its aqueous solution is rendered milky by tannic acid, then colored green by the addition of a few drops of fuming nitric acid. It is colored deep red by ferric chloride, passing to violet-red on copious dilution with water. It must not be affected by hydrogen sulphide.

It is incompatible with acids, alkalies and tannins.

If 1 Gm. antipyrine salicylate is weighed in a separator, treated with 25 Cc. water and 10 Cc. sodium hydroxide test solution, and the liquid then extracted with chloroform, the latter on evaporation should yield a residue which when dry should weigh 0.57-0.58 Gm., melt at 113 degrees and respond to the tests for antipyrine.

The solution remaining in the separator, acidified, and extracted with chloroform, the chloroform allowed to evaporate, should yield a residue of white needle-like crystals, which when dry melt at 155°-156° and respond to the tests for salicylic acid.

If 1 Gm. antipyrine salicylate is dissolved in 50 Cc. diluted alcohol, a few drops of phenolphthalein added, from 30.5-30.8 Cc. tenth normal alkali should be required to produce a permanent pink color, indicating a salicylic acid content of 42.10-42.50 per cent.

Dosage.—For hypodermic injection 0.1 Gm. (1½ grains) to 0.5 Gm. (7½ grains). For internal administration 0.05 Gm. (¾ grain) 3 to 4 times daily.

Manufactured by Farbwerke, vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany. (Victor Koechl & Co., New York.) U. S. trademark No. 75,046.

SODIUM ARSANILATE—Sodii Arsanilas.—Sodium Aniline Arsonate. Sodium Aminophenyl Arsonate. Sodium arsanilate, $C_6H_4(NH_2)$ (AsO.OH.ONa) $= C_6H_7O_3NAsNa$, is the sodium salt of arsanilic acid, $C_6H_4(NH_2)$ (AsO.(OH)$_2$),1:4.

It is prepared by condensing aniline and arsenic acid, eliminating water and isolating the arsanilic acids. The sodium salt is prepared by the usual methods.

Sodium arsanilate occurs as white, odorless crystals soluble in (5 or 6 parts) of water and is more soluble in warm water. It has a faint salty taste. On standing, the aqueous solution assumes a yellowish tint.

Sodium arsanilate crystallizes with somewhat varying amounts of water of crystallization. The arsenic content varies in different preparations from 23 to 26 per cent.

An acid solution of sodium arsanilate is not affected by hydrogen sulphide in the cold; when the solution is warmed the arsenic may be completely precipitated by hydrogen sulphide. If a solution of sodium arsanilate is treated with hydrochloric acid and potassium iodide, iodine is set free. The resulting liquid, whether freed of iodine or not, gives, even in the cold, a precipitate of arsenic sulphide when treated with hydrogen sulphide.

The arsenic and water content of sodium arsanilate may be determined by the methods given in THE JOURNAL A. M. A., Sept. 21, 1907, p. 1041.

An aqueous solution of the salt gives with mineral acids a white precipitate of arsanilic acid, soluble in excess of acid. An aqueous solution of the salt gives with silver nitrate solution a white precipitate of silver arsanilate. An aqueous solution of the salt, after the addition of hydrochloric acid and sodium nitrate gives a deep red coloration with a solution of β-naphthol in caustic soda.

Actions and Uses.—The arsenic of the arsanilic acid is liberated very slowly in the system, thus producing the ordinary therapeutic effects of arsenic, with a more continuous and less toxic action and less irritation. Toxic effects from excessive doses have been frequently noted, although the toxicity of sodium arsanilate is stated to be about 1/40 of that of arsenic trioxide. The poisonous effects appear to be due largely to the arsenic component, the aniline taking no part in them. It is claimed that the use of sodium arsanilate is not followed by irritation, abscess formation, etc., which sometimes follow the use of other preparations of arsenic. The use of sodium arsanilate in large doses has occasionally been followed by degeneration of the optic nerve, leading to blindness.

Sodium arsanilate has been recommended for the conditions which are favorably influenced by arsenic, such as anemia, nervous affections and diseases of the skin. It is said to have been very successful as a remedy for trypanosomiasis, both of animals and of man, and is also said to be useful in other protozoal diseases, such as syphilis, malaria, kala-azar, etc.

Dosage.—0.02 to 0.2 Gm. (⅓ to 3 grains) hypodermically every other day, gradually increasing, if necessary, until the single dose reaches 0.65 Gm. (10 grains) and until a total of 6.5 Gm. (100 grains) have been given. The drug should not be given by the mouth, as it is decomposed by the acid contents of the stomach, and toxic symptoms may result.

Proprietary preparations:

Sodium arsanilate was first introduced in the form of *Atoxyl.*

ATOXYL.—Atoxyl is sodium arsanilate containing about 26 per cent. of arsenic and corresponding closely to the formula $C_6H_4(NH_2)$. (AsO.OH.ONa)$+3\ H_2O$. It is a white powder having the properties given above.

Manufactured by Vereinigte Chemische Werke Actiengesellschaft, Charlottenburg, Germany. (Victor Koechl & Co., New York.) U. S. trademark No. 38,879.

Atoxyl Hypodermic Tablets, 1/3 grain.—Each tablet contains atoxyl 0.02 Gm. (⅓ grain).

SOAMIN.—Soamin is a form of sodium arsanilate containing approximately 22 per cent. of arsenic and corresponding to the formula $C_6H_4(NH_2)$. (AsO.OH.ONa)$+5\ H_2O$. It is a white crystalline substance having the properties given above.

Manufactured by Burroughs, Wellcome & Co., London, Eng., and New York. British trademark No. 302,133; U. S. trademark applied for.

Tabloid Soamin, 5 grains.—Each tablet contains soamin 0.3 Gm. (5 grains).

Tabloid Soamin, 1 grain.—Each tablet contains soamin 0.065 Gm. (1 grain).

ARSENOFERRATIN—Sodii Arsenoferrialbuminas.—Sodium Arsenoferrialbuminate.—Arsenoferratin is an arsenic iron albumin compound, obtained by introducing the element arsenic into the molecule of ferrialbuminic acid. Arsenoferratin contains iron in the ferric state, in organic combination equivalent to 6 per cent. metallic iron and arsenic, equivalent to 0.06 per cent. elementary arsenic.

Arsenoferratin is a brown, almost odorless and tasteless powder. It is soluble in water and easily soluble in dilute alkaline solutions.

Actions and Uses.—Arsenoferratin has the pharmacologic action of organic compounds of iron and of arsenic.

Dosage.—0.5 Gm. (7½ grains) three to four times daily.

Manufactured by C. F. Boehringer & Soehne, Waldhof, Mannheim, Germany. (Merck & Co., New York). Not patented. U. S trademark No. 24,228.

Arsenoferratin Tablets.—Each tablet contains arsenoferratin 0.25 Gm. (4 grains).

Arsenoferratose.—Liquor Ferratini Arsenati.—Arsenoferratose is a 5 per cent. solution of arsenoferratin.

Arsenoferratin, 5 parts, is dissolved with the aid of a small quantity of sodium hydroxide in water, 68 parts, glycerin, 20 parts, alcohol, 6 parts, and Angostura essence, 1 part.

Dosage.—4 to 8 Cc. (1 to 2 fluidrams) three to four times daily.

For the determination of Iron and Arsenic in Arsenoferratose, the following methods are furnished:

Twenty-five Cc. of arsenoferratose are evaporated to a viscid consistency in a capacious tared crucible and the residue heated in a drying oven at 100 degrees C. for three hours to constant weight. After the crucible and its contents have been allowed to cool in a desiccator, it is weighed. The weight of the evaporated residue multiplied by 4 should be about 23. The weighed residue is now carefully incinerated, and finally ignited. After it has cooled, it is moistened with nitric acid, and again ignited, and finally taken up with 10 Cc. hydrochloric acid. The solution is diluted with 30 Cc. water, and when cold, 3 Gm. potassium iodide are added and the mixture allowed to stand for an hour in a well-stoppered bottle at the ordinary temperature. It is then titrated with decinormal sodium thiosulphate solution. The iodine liberated should require about 12.5 Cc. of tenth normal thiosulphate solution.

Fifty Cc. of the arsenoferratose contained in a distillation flask ated to about one-third of its original volume. To the residue are of about 500 Cc. capacity, are heated on a water bath and evapor- now added 80 Cc. of arsenic-free concentrated hydrochloric acid and 20 Cc. arsenic-free, 25 per cent. solution of ferrous chloride, and the arsenic chloride distilled over, the receiver being kept well cooled by means of cold water. The contents of the receiver are then supersaturated with sodium bicarbonate, and the arsenic then titrated with the tenth-normal iodine solution: 0.4 Cc. decinormal iodine solution should be required, corresponding to a content of 0.003 Gm. in 100 Cc. arsenoferratose.

ARSEN-TRIFERRIN—Arsentriferrinum.—Arsen-Triferrin is an iron aresnoparanucleate containing arsenic in organic combination and standardized to contain a definite amount of arsenic by diluting with iron paranucleate. It should contain about 16 per cent. of iron, 0.1 per cent. of arsenic (As.), and 2.5 per cent of phosphorus, all in organic combination.

Arsen-Triferrin is an orange colored, tasteless powder, soluble in dilute alkalies from which it can be precipitated by the addition of an acid. It is also soluble in about 8 per cent. of hydrochloric acid on warming.

The determination of the amount of iron, arsenic and phosphorus in arsentriferrin is carried out according to the method in "Prüfungsvorschriften für die pharmazeutischen Spezialpräparate." (Knoll & Co.)

Actions and Uses.—Arsen-Triferrin passes through the stomach unchanged and undissolved, but is dissolved in the intestines and absorbed. This behavior prevents injurious action of arsenic on the gastric mucous membrane.

Arsen-Triferrin is said to be useful in cases of anemia which are rebellious to iron alone, and in neurasthenia, hysteria, and in skin diseases.

Dosage.—5 grains three times a day after meals.

Manufactured by Knoll & Co., Ludwigshafen a. Rh., Germany and New York (Merck & Co., New York). U. S. trademark No. 36,747.

Arsen-Triferrin Tablets, 5 grains.—Each tablet is said to contain arsen-triferrin 0.3 Gm. (5 grains).

Arsen-Triferrol. Elixir Arsen-Triferrini. Arsen-Triferrol is an elixir of arsen-triferrin containing in each 4 Cc. (1 fluidram) about 0.06 Gm. (1 grain) of arsen-triferrin in a menstruum containing 15 per cent of alcohol. It is prepared by dissolving a soluble form of arsen-triferrin in a vehicle consisting of water, alcohol, tincture of orange, compound tincture of cardamom and vanillin.

ASPIRIN.—Acidum Acetylsalicylicum.—Acetylsalicylic Acid. Acidum Acetylosalicylicum (Pharm. Helvetica, edit. 4; Pharm. Danica, 1907; Pharm. Svecica, edit. 9; Pharm. Hungarica, edit. 3)—Acidum Acetylsalicylicum (Pharm. Française, 1908)—Acetylsalicylic acid, $C_6H_4.((CH_3CO).COOH,1{:}2 = C_9H_8O_4$, is the acetyl derivative of salicylic acid.

It is prepared by the prolonged heating of 50 parts of salicylic acid and 75 parts of acetic anhydride at about 150° C. (302° F.)

under a reflux condenser, and subsequent purification, by recrystallization from chloroform.

It forms small, colorless, crystalline needles, melting at 135° C. (275° F.), odorless and having an acidulous taste. It is soluble in 100 parts of water and freely soluble in alcohol or ether. It is readily split up on boiling with water or with alkalies with the production of acetic acid and salicylic acid or a salicylate.

It forms clear, colorless solutions, which do not develop a violet color on the addition of ferric chloride unless previously hydrolysed by boiling with sodium hydroxide. It gives no reaction with silver nitrate, and should leave no residue when heated on platinum foil.

It is incompatible with heat, moisture, alkalies, their carbonates and bicarbonates. It keeps well when properly protected.

Actions and Uses.—It acts like salicylic acid, over which it possesses the advantage of producing less of the undesired local and systemic side effects, on account of the slow liberation of the salicylic acid. It is claimed to pass the stomach unchanged, the decomposition beginning in the intestine.

Dosage.—0.3 to 1 Gm. (5 to 15 grains) in capsules or wafers, or dissolved in sweetened water, or dry on the tongue, followed by a swallow of water. The powder should be dispensed in wax paper.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 644,077 (Feb. 27, 1900; expires 1917). U. S. trademark No. 32,805.

BARIUM CHLORIDE—Barii Chloridum.—Baryum Chloratum (Pharm. Germanica, edit. 4; Pharm Helvetica, edit. 4). Barium Chloride ($BaCl_2 2H_2O$) is the barium salt of hydrochloric acid.

Barium chloride occurs as colorless trimetric plates or glistening scales, odorless, non-efflorescent and having an unpleasant, bitter, sharp, saline taste. It dissolves in 2.5 parts cold and in 1.5 parts boiling water, forming a neutral solution; but is insoluble in alcohol. Barium chloride becomes anhydrous when dried at 120° C. (248° F.).

An aqueous solution of the salt yields, with diluted sulphuric acid, a heavy white precipitate, insoluble in strong acids, and with silver nitrate a curdy, white precipitate, insoluble in nitric acid but readily soluble in ammonia water. Diluted alcohol, after remaining in contact with the salt for several hours, should, on ignition, give a pure yellowish-green flame free from red (absence of traces of strontium). An aqueous solution of barium chloride should not be precipitated by ammonium sulphide nor should any residue remain after adding excess of diluted sulphuric acid to the solution, filtering, and evaporating to dryness. Twenty Cc. of the aqueous solution (1 to 20) must not turn blue on the addition of 0.5 Cc. of potassium ferrocyanide T. S.

Action and Uses.—Barium chloride is a toxic substance, its most striking effects being exerted upon muscle tissue, especially unstriped and heart muscle. In large doses it affects the spinal cord and medulla. By actively stimulating peristalsis, through action on the muscle wall, and by its direct irritant action, it readily produces vomiting and purging. It strengthens the cardiac contraction by direct action on the heart muscle, and by this means and still more by direct action on the vessel walls it greatly increases blood pressure, acting like digitalis. It acts on the muscles like veratrin. It first greatly excites and then paralyzes the spinal cord and medulla. Given in very dilute solution, absorption is small and the barium is deposited in the bones. Injected intravenously it causes tonic and clonic spasms, because of stimulation of the spinal cord and medulla.

In fatal doses it causes hemorrhages into the stomach, intestines and kidneys.

Its clinical use has been attended with little success, chiefly because of the gastrointestinal irritation and high toxicity. It has, however, been used in cardiac disease with insufficient blood pressure, as a general "tonic," and with less reason in tremors, in scleroses of the central nervous system, internally and locally in varicose veins, etc.

In poisoning the most direct antidote against the portion remaining in the gastrointestinal tract is sodium sulphate, which produces insoluble barium sulphate.

Its use is attended with considerable danger.

Dosage.—0.006 to 0.003 Gm. (1/10 to ½ grain) or 2 to 4 Cc. (30 to 60 minims) of a 1 per cent. solution (5 grains to the fluidounce). Fatal, 0.80 to 0.90 Gm. (13-15 grains). It should always be well diluted before giving.

Internally used in syphilis, scrofula and tumor albus in doses of 0.03-0.10 Gm. (½ to 1½ grains) 3 to 4 times per day; for heart disturbances 0.2-0.4 Gm. (3 to 6 grains) per day. Maximum dose per day 0.6 Gm. (9 grains). Externally employed as an eye-wash in scrofulous eye affections in 10 per cent. solution.

BENZOSALIN. — Methylis Benzoyl-Salicylas.—Benzoyl-Salicylic-Acid-Methylester—Methyl Benzoyl-Salicylate. Benzosalin is methyl benzoyl salicylate $C_6H_4.O(CH_3).COO(C_6H_5CO)$, $1{:}2 = C_{15}H_{12}O_4$ the benzoyl salicylic acid ester of methyl alcohol.

Benzosalin is prepared by a reaction between the methylester of salicylic acid and benzoyl chloride in the presence of sodium hydroxide. The resulting product is washed with water and after drying is crystallized out from alcohol.

Benzosalin consists of fine, white crystals with a very faint aromatic odor. It melts at about 85° C. (185° F.). It burns leaving no residue. It dissolves readily in chloroform, benzene and in 35 parts of 90 per cent. cold alcohol, also in pure concentrated sulphuric acid.

Actions and Uses.—Benzosalin is said to pass the stomach unchanged and to be decomposed into its constituents, benzoic and salicylic acids in the intestines. It is said to be free from the undesirable by-effects of salicylic acid. It is claimed that benzosalin is an intestinal antiseptic.

Benzosalin is said to be useful in rheumatic affections, such as arthritis, neuralgia, sciatica and migraine, and in arthritis deformans.

Dosage.—0.5 to 1 Gm. (7½ to 15 grains). Daily dose 3 to 4 Gm. (45 to 60 grains) in powder or tablets.

Manufactured by F. Hoffmann-La Roche & Co., Basel, Switzerland. (The Hoffmann-La Roche Chemical Works, New York.) U. S. Patent No. 799,706 (Sept. 19, 1905; expires 1922). Controlling Benzoyl Salicylic Acid. Name "Benzosalin" registered No. 58,757.

Benzosalin Tablets, 5 grains.—Each tablet contains benzosalin 0.3 Gm. (5 grains).

BERBERINE HYDROCHLORIDE. — Berberinæ Hydrochloridum.—Berberine hydrochloride is the hydrochloride, $C_{20}H_{17}NO_4HCl + 2H_2O$, of an alkaloid obtained from *Hydrastis canadensis* and *Berberis vulgaris.*

Berberine hydrochloride occurs as bright yellow acicular crystals of amorphous powder, slightly soluble in alcohol *to which it imparts a deep yellow color.* It is soluble in 300 parts cold water, but dissolves more easily in hot water.

An aqueous solution of berberine or its salts treated with chlorine or bromine water produces a blood red color. Bromine water in excess precipitates the reddish-brown berberine tetra-
[illegible]
onverted by
yellow-brown

Ammonium sulphide precipitates from an alcoholic solution of berberine sulphate the polysulphide $(C_{20}H_{17}NO_4)_2H_2S_5$ which crystallizes in brown-black needles.

Berberine solutions even if very dilute when treated with potassium iodide solution yield a yellow precipitate of berberine hydroiodide.

Action and Uses.—Given by mouth, it acts as a bitter stomachic. Very large doses, although not fatal, cause diarrhea, tremors, general weakness, low blood pressure (from depression of vasomotor center and of cardiac muscle), rapid pulse (depression of vagus endings) and respiration. Recovery is slow. Nephritis may be present. Subcutaneous injection kills by paralysis of respiration, with symptoms of asphyxia and paralysis. It has been used as a bitter tonic for diarrhea, the vomiting of pregnancy and as a febrifuge.

Dosage.—0.06 Gm. to 0.3 Gm. (1 to 5 grains). As much as 20 grains have been taken without obvious effect other than a loose stool.

BETANAPHTHOL BENZOATE—Naptholis Benzoas.—Benzonaphthol. Benzoyl-Beta-Naphthol.—Beta-naphthol benzoate is beta-naphthyl benzoate, $C_6H_5.COO.C_{10}H_7 = C_{17}H_{12}O_2$, the benzoic ester of beta-naphthol.

Beta-naphthol benzoate is obtained by heating beta-naphthol and benzoyl chloride together at 170° C. (338° F.), extracting the product with alcohol, and crystallizing.

It forms colorless needles, or a white crystalline powder, colorless and tasteless, melting at 107-110° C. (224.6-230° F.). It is almost insoluble in water, but readily soluble in alcohol and in ether; also soluble in chloroform, in glycerin and in olive oil.

It is decomposed by heating with *caustic alkalies* into naphthol and a benzoate which will then give their characteristic reactions.

To test beta-naphthol benzoate for the presence of beta-naphthol it should be shaken several times with dilute solution of sodium hydroxide (1:10) and immediately filtered. If beta-naphthol is present in considerable amount it will separate as a turbidity or precipitate after acidifying with dilute sulphuric acid. If the amount of beta-naphthol is small no precipitate appears, but the alkaline solution shows a bluish fluorescence and if it is boiled with chloroform a green color is produced.

A solution of beta-naphthol benzoate should not give a violet color with chloride of lime or solution of iodine and alkali.

It is incompatible with *antipyrine*, camphor, phenol, ferric chloride, menthol, potassium permanganate, or ethyl carbamate (urethane).

If 1 Gm. beta-naphthol benzoate be shaken with 10 Cc. water and the solution filtered, the filtrate acidified with nitric acid, should not become turbid on addition of silver nitrate solution.

Beta-naphthol benzoate heated on a platinum foil should leave no weighable residue.

Actions and Uses.—Beta-naphthol benzoate is split up into its constituents on reaching the intestinal tract and is believed to act as an antiseptic. It is said to be diuretic. It is used internally as an intestinal antiseptic in diarrhea and typhoid fever. Externally it is said to be useful as a parasiticide in the form of 3 to 10 per cent. ointment, and has been used in psoriasis, eczema, scabies, etc.

Note: Wide difference of opinion exists among authorities as to the actual efficiency of any intestinal antiseptics and most urinary antiseptics. Whatever opinion regarding this is followed, it should be remembered that if used freely or for a long time any of them may have irritating effects upon the digestive tract or undesirable effects upon other tissues. Reasonable caution should therefore be exercised in using them.

Dosage.—0.2 to 0.5 Gm. (3 to 8 grains); maximum dose, single, 1 Gm. (15 grains), daily 4 Gm. (60 grains).

Non-proprietary preparations:

Beta-naphthol Benzoate, Heyden. Manufactured by Fabrik von Heyden, Radebeul near Dresden, Germany (Merck & Co., New York). Not patented or trademarked.

Benzonaphthol, Farbwerke. Manufactured by Farbwerke, vorm. Meister Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York). Not patented or trademarked.

BETOL—Naphtholis Salicylas.—Naphthalol—Naphthol-Salol—Salinaphthol.—Betol is beta-naphthyl salicylate, $C_6H_4.OH.COO(C_{10}H_7) = C_{17}H_{12}O_3$, the salicylic acid ester of beta-naphthol.

Betol is obtained by heating beta-naphthol-sodium and sodium salicylate with phosphorus oxychloride at 120°-130° C. (248° to 266° F.).

It is a white, shining crystalline powder, colorless and tasteless melting at 95° C. (203° F.). It is insoluble in cold or hot water or glycerin, difficultly soluble in cold alcohol or turpentine, easily soluble in boiling alcohol, in ether, in benzene, and in warm linseed oil. In the cold it is not changed by acids or alkalies of moderate concentration. When heated with alkalies it is decomposed into its constituents, which, if the solution is acidulated, will crystallize.

It is distinguished from salol by its higher melting point and by the production of a brownish-green color, when a trace of nitric acid is added to its yellow colored solution in pure sulphuric acid. It burns on platinum foil, leaving no residue (absence of fixed mineral impurities).

If 1 Gm. of betol is shaken with 30 Gm. of boiling water and filtered through a moistened filter, the filtrate should not have an acid reaction (absence of salicylic, hydrochloric or phosphoric acid) nor should it after cooling show a crystalline deposit (salicylic acid or beta-naphthol) and should not become turbid on the addition of silver nitrate (chlorides or phosphates) or barium nitrate (absence of sulphate) nor should it give a violet color with solution of ferric chloride.

Actions and Uses.—Betol undergoes no change in the stomach, but is split up into its original compounds when it reaches the intestinal tract by the pancreatic juice and intestinal secretions. It is believed to act as an intestinal antiseptic and, being excreted in the urine, to act in a similar way in the bladder. (See note under Beta-Naphthol Benzoate.)

It has the antirheumatic properties of salicylic acid. It is said to be useful for intestinal fermentations, catarrh of the bladder, particularly in gonorrheal cystitis, for rheumatism, etc.

Dosage.—0.3 to 0.5 Gm. (4 to 8 grains) in cachets, milk or emulsion.

Manufactured by the Heyden Chemical Works, New York. U. S. trademark.

BILE SALTS

The bile of man and of several animals contains in varying proportions the sodium salts of conjugated cholic acids; in ox and human bile especially glycocholic acid $C_{26}H_{43}O_6N$; and taurocholic acid, $C_{26}H_{45}O_7NS$. Fresh ox gall is said to contain about 3 per cent. each of sodium glycocholate and sodium taurocholate.

The sodium glycocholate and taurocholate may be separated in the following manner: Dry ox bile is treated with absolute alcohol and the tincture precipitated by ether in excess. Both salts are deposited and the glycocholate crystallizes upon standing, the taurocholate remaining in amorphous form, resembling oily or resinous matter. If the deposit is dissolved in water, solution of lead acetate will throw down a lead glycocholate, while the addition of lead subacetate to the remainder will precipitate the taurocholate (U. S. Dispensatory, p. 490).

Tests: All the bile acids respond to Pettenkofer's test. A small portion of the salt is dissolved in a little concentrated sulphuric acid in a small porcelain dish and warmed, care being taken that the temperature does not rise higher than 60° to 70° C. A 10 per cent solution of cane sugar is then added drop by drop while the liquid is stirred with a glass rod. If compounds of cholic acid are present a beautiful red color will appear, which does not disappear at room temperature, but usually in the course of a day becomes bluish violet. The red liquid shows in the spectrum two absorption bands, one at F and the other between D and E near to E. Care must be taken not to heat too much nor to add too much sugar. The sulphuric acid must be free from sulphurous acid and the lower oxides of nitrogen. As albumin, oleic acid, amyl alcohol, morphine, etc., may give a similar reaction, spectroscopic examination should not be omitted in doubtful cases (Hammarsten, Lehrbuch der physiolog. Chemie, p. 312).

Furfurol Test (Mylius): The substance is dissolved in alcohol and for every one cubic centimeter of the alcoholic solution, one drop of a 1:1000 furfurol solution and one Cc. of concentrated sulphuric acid are added and the mixture cooled, if necessary, so that the temperature may not rise too high. The same color reaction occurs as in Pettenkofer's test.

Actions and Uses.—The bile salts constitute the main active principles of bile, and therefore share the actions and uses of the latter, perhaps with the advantage of more constant composition. When injected into the circulation they cause severe nervous and cardiac depression, not observed when they are given by mouth. They are generally credited with a slight antiseptic and laxative action, with enhancing the efficiency of the resinous hydragogue cathartics, and with emulsifying and hence favoring the absorption of fat. They stimulate the secretory activity of the liver, increasing both the fluids and solids of the bile. While they are regarded as the most powerful of the so-called cholagogues, it is doubtful if even their effect is very pronounced.

They may be used in obstructive jaundice, although the rationale is somewhat doubtful; their use in biliary fistula is more reasonable, if the nutrition is noticeably affected.

Proprietary Preparations:

BILEIN—Sodii glyco-taurocholas bovis—Abbott.—Bilein is *the name given to a mixture of the essential salts of the bile.*

Actions and Uses.—See Bile Salts.

*Manufactured by the Abbott Alkaloidal Co., Chicago. U. S. trade*mark No. 44,140.

Bilein Pills, 1/4 grain.—Each pill contains bilein 0.015 Gm. (1/4 grain).

Bilein Pills, 1/8 grain.—Each pill contains bilein 0.008 Gm. (1/8 grain).

Bilein Pills, 1/12 grain.—Each pill contains bilein 0.006 Gm. (1/12 grain).

BILE SALTS-Fairchild.—Bile salts-Fairchild is a *preparation* obtained from fresh ox-gall, *consisting essentially of sodium* glycocholate and sodium taurocholate, in the proportion existing in ox bile.

Action and Uses.—See Bile Salts.

Dosage.—0.13 to 0.4 Gm. (2 to 6 grains); 4 to 5 Gm. (60 to 75 grains), per day.

Manufactured by Fairchild Bros. & Foster, New York.

COLALIN.—*Colalin consists essentially of a mixture of hyoglycocholic and hyotaurocholic acids, obtained from bile.* To preserve the pulverulent condition a little magnesium carbonate is added.

Colalin is a yellow powder of faint odor and persistent bitter taste. It melts at 103° to 107° C. It is slightly soluble in water and acid toward litmus.

Colalin should be readily soluble in alcohol and this solution should rotate polarized light to the right. It should dissolve almost entirely in a dilute solution of sodium carbonate with evolution of carbon dioxide and in a dilute solution of sodium hydroxide. The solution in *sodium hydroxide* should not be rendered turbid by the addition of barium hydroxide T. S. (absence of fatty acids). It should not contain more than a trace of sulphur (absence of taurin).

Actions and Uses.—See Bile Salts, above.

Dosage.—0.015 to 0.030 Gm. (¼ to ½ grain) three to four times daily; for children from 0.008 to 0.015 Gm. (⅛ to ¼ grain).

Manufactured by Rufus Crowell & Co., Somerville, Mass. (Schieffelin & Co., New York).

Colalin Tablets, ½ grain.—Each tablet contains colalin 0.03 Gm. (½ grain).

Colalin Tablets, ¼ grain.—Each tablet contains colalin 0.015 Gm. (¼ grain).

Colalin Tablets, ⅛ grain.—Each tablet contains colalin 0.008 Gm. (⅛ grain).

BISMUTH SUBCARBONATE PREPARATIONS.

CREMO-BISMUTH—Mistura Bismuthi Subcarbonatis Hydrati, Mulford.

Cremo-bismuth is a mixture said to consist of bismuth subcarbonate suspended in water in a finely divided state, each 100 Cc. representing the equivalent of 8.66 Gm. (40 grains in one fluid ounce) of bismuth subnitrate.

Dosage.—4 to 16 Cc. (1 to 4 fluidrams) every two or three hours.

Prepared by the H. K. Mulford Co., Philadelphia. U. S. trademark No. 29,335.

LAC BISMO—Mistura Bismuthi, Hart.—Lac Bismo is a mixture said to consist of bismuth hydroxide and bismuth subcarbonate, suspended in water, in a finely divided state, and containing 0.16 Gm. (2½ grains) of the salts in 4 Cc. (1 fluidram).

Dosage.—4 to 16 Cc. (1 to 4 fluidrams).

Prepared by E. J. Hart & Co., Ltd., New Orleans, La. U. S. trademark.

BISMUTH SUBGALLATE PREPARATIONS.

BISMUTH SUBGALLATE.—Bismuth subgallate is official in the United States Pharmacopeia. For description see the pharmacopeia or the Physicians Manual of the Pharmacopeia and the National Formulary.

AIROL—Bismuthi Iodosubgallas—Bismuth Oxyiodogallate. Airoform.—Airol. $C_6H_2(OH)_3(COOBiI(OH) = C_7H_5O_6IBi$., is a combination of bismuth oxyiodide (subiodide) and gallic acid.

It is prepared by heating molecular quantities of bismuth subgallate and hydriodic acid or bismuth oxyiodide and gallic acid, in the presence of water, until a grayish-green product results, which is drained and dried.

It is a voluminous grayish-green, odorless and tasteless powder, insoluble in alcohol, ether, chloroform, and olive oil, slightly soluble in glycerin. It is practically insoluble in water, communicating to water a red color on standing, slowly in the cold, but readily when heated, being decomposed with liberation of iodine and bismuth subgallate. It is readily soluble, with decomposition, in dilute alkalies and mineral acids. It is decomposed on exposure to moist air, turning red, but in admixture with glycerin and a little water it long remains unaltered.

Airol may be identified by the appropriate tests for its components.

It is incompatible with water and calomel. It should not be exposed to moist air.

Actions and Uses.—As it liberates iodine in the nascent state in the presence of wound secretion it is said to be useful as a substitute for iodoform in the treatment of wounds, burns, skin diseases, gonorrhea, etc.

Dosage.—It is used externally in the pure state or diluted with talc, or in the form of a 10 per cent. suspension in equal parts of glycerin and water, or as a 10 to 20 per cent. ointment with 2 parts of petrolatum and 7 parts of wool fat.

Manufactured by F. Hoffmann-LaRoche & Co., Basel, Switzerland (The Hoffmann-LaRoche Chemical Works, New York). U. S. patent No. 544,104 (Aug. 6, 1895; expires 1912). German patents Nos. 80,399 and 82,593. U. S. trademark No. 79,760.

BISMAL—Bismuthi Methylen-Digallas.—Bismal, $4(C_{15}H_{12}O_{10}).3Bi(OH)_3 = Bi_3C_{60}H_{57}O_{49}$, is a compound of bismuth hydroxide and methylendigallic acid.

It is obtained by digesting 4 molecules of methylendigallic acid with three molecules of bismuth hydroxide in water.

It is a voluminous gray-brown powder, insoluble in water or gastric juice, but soluble in alkalies, forming yellowish red solutions.

Actions and Uses.—Bismal is an astringent and is said to be useful for the treatment of chronic diarrhea.

Dosage.—0.12 to 0.3 Gm. (2 to 5 grains) in cachets or powder.

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York). U. S. patent No. 605,246 (June 7, 1898; expires 1915). German patent No. 87,099 (dropped in 1890).

BISMUTH AND IRON CITRATE (SOLUBLE), Wellcome Brand—Bismuthi et Ferri Citras, Wellcome.—Bismuth and iron citrate (soluble), Wellcome brand is a "scale salt" containing bismuth citrate and ferric citrate in amounts corresponding to from 38 to 40 per cent. each of the respective anhydrous salts (corresponding to 20 to 21 per cent. bismuth and 8.7 to 9.1 per cent. iron), the combination being rendered soluble in water by means of ammonia.

Bismuth and iron citrate (soluble) occurs in yellowish-green scales, readily soluble in water, having a saline, mildly ferruginous taste.

A solution of bismuth and iron citrate (soluble) is acid toward litmus; addition of dilute acids or of ammonia water renders the solution darker but does not cause precipitation; addition of sodium hydroxide T. S. causes formation of a reddish-brown precipitate and evolution of ammonia.

The iron content of bismuth and iron citrate soluble may be determined by the methods prescribed for ferri et ammonii citras U. S. P. The amount of bismuth is determined by precipitating by hydrogen sulphide from an acid solution, dissolving the bismuth sulphide obtained in dilute nitric acid, precipitating the bismuth from this solution by ammonium carbonate and weighing as bismuth oxide.

Actions and Uses.—It has the properties of iron and soluble bismuth salts. Its administration is proposed by the manufacturer in cases of dyspepsia accompanied by anemia; that the sedative action of bismuth may be exerted on the digestive organs, while the iron may combat the anemia.

Dosage.—0.3 to 0.65 Gm. (5 to 10 grains).

Manufactured by Burroughs, Wellcome & Co., London and New York. Not patented or trademarked.

BISMUTH AND LITHIUM CITRATE (SOLUBLE), Wellcome Brand—Bismuthi et Lithii Citras Solubilis, B. W. & Co.—Bismuth and lithium citrate (soluble), Wellcome brand, is a "scale salt" of bismuth and lithium citrate containing 40 to 45 per cent. of bismuth (Bi) and 2.5 to 3 per cent. of lithium.

Bismuth and lithium citrate (soluble) occurs in colorless scales, readily soluble in water. Its aqueous solution is acid toward phenolphthalein, but alkaline toward lithmus T. S.

Tests. If 1 Gm. of the salt is warmed with 10 Cc. potassium hydroxide no ammonia is evolved (absence of ammonium compounds).

Actions and Uses.—Recommended by the manufacturers as a convenient form of medication when the effects of both lithium and bismuth are desired, as in gouty dyspepsia.

Dosage.—0.13 to 0.3 Gm. (2 to 5 grains).

Manufactured by Burroughs, Wellcome & Co., London, England, and New York. Not patented or trademarked.
patented in U. S.

BORNYVAL.—Bornyval is a name applied to capsules containing borneol isovalerate $C_{10}H_{17}O.C_5H_9O$, the isovaleric acid ester of borneol, 0.25 Gm. (4 minims).

It is prepared by the condensation of equal molecular quantities of borneol and isovaleric acid.

Borneol isovalerate is a clear aromatic liquid, having an odor resembling oil of rosemary and at the same time a weak odor and taste of valerian. It is insoluble in water, but dissolves in all proportions of alcohol and ether. The liquid boils at 255° to 260° C. (417° to 426° F.) under ordinary pressure. At a pressure of 50 mm. it boils at 150° to 170° C. (302° to 338° F.). Its specific gravity is 0.945 to 0.951; it is dextrorotatory. The alcoholic solution 1:10 after the addition of a drop of phenolphthalein solution should be distinctly reddened by a drop of tenth-normal alkali.

Actions and Uses.—As borneol isovalerate forms a large part of oil of valerian, its action is similar to that of the official drug. It reduces reflex excitability and acts as a nervous sedative.

It is said to be useful in the various neuroses, especially those of the circulatory, digestive and central nervous systems.

Dosage.—0.25 to 0.75 Gm. (4 to 12 minims) from two to four times daily. It is best given after meals with some milk, coffee or similar drink to avoid eructations.

Manufactured by J. D. Riedel, Aktiengesellschaft, Berlin, Germany (Riedel & Co., New York). U. S. trademark No. 56,451. Not patented in U. S.

BROMETONE.—Tribrom-Tertiary-Butylalcohol. — Acetone-Bromoform.—Brometone is 1,1,1-tribrom-2-methyl-propan-2-ol, $CBr_3.C(OH)(CH_3).CH_3 = C_4H_7OBr_3$, produced by the reaction of acetone on bromoform.

Made by the action of caustic alkalies on a mixture of bromoform and acetone.

Occurs in fine white, prismatic crystals which possess a camphoraceous odor and taste. It is slightly soluble in water, soluble in alcohol, ether, benzin and most organic solvents. It melts at about 167° F. (332.6° F.) and volatilizes on exposure to air.

Actions and Uses.—Brometone is claimed to have the sedative action of the bromides without the disadvantage of producing bromism. In doses of 0.3 Gm. (5 grains) four or five times a day, in adults, it is claimed to cause no unpleasant results and to produce no disturbance of the digestive organs, and to have no appreciable effect on the secretions. Its action is prompt and its effect is manifest for several hours. In doses exceeding 1.6 Gm. (25 grains) daily it may produce dizziness, vertigo, anorexia, and mental hebetude, all of which symptoms disappear on discontinuance of its use. Therapeutically it has been said to be useful in mild conditions of excitation and insomnia, in so-called narcotic abstinence, in hysteria, and in nervous affections generally. It relieves some forms of cough and is said to produce amelioration in some cases of epilepsy. It has been used to relieve dizziness due to labyrinthine disturbances.

Dosage.—The dose is 0.3 Gm. (5 grains), dry or in capsules, to be repeated two or three times during twenty-four hours.

Manufactured by Parke, Davis & Co., Detroit, Mich. U. S. trademark.

BROMIPIN.—Brominized Sesame Oil. Merck.—Bromipin is a bromine addition product of sesame oil.

It is prepared by the action of bromine chlorid on sesame oil, in sufficient quantities, theoretically calculated, to produce the required brominization.

It is a yellow, oily liquid, having a purely oleaginous taste, and having a sp. gr. of 0.995 to 0.997.

If to 1 Cc. of bromipin in 1 Cc. of chloroform a few drops of phenolphthalein solution be added, the addition of one drop of half normal potassium hydroxide should produce a red color (limit of acidity). Estimation of bromine; 1 Gm. of bromipin 10 per cent., or 0.3 Gm. of bromipin 33⅓ per cent. is boiled with a solution of 2 Gm. of potassium hydroxide in 10 Cc. of alcohol until saponified. The solution is evaporated on a water bath, the residue is charred and the char is repeatedly extracted with small portions of water, and these are passed through a filter. To the filtrate 5 Cc. of nitric acid, 15 Cc. of tenth-normal silver nitrate and 1 Cc. ferric-ammonium sulphate test solution are added, and the excess of silver nitrate is determined with tenth-normal ammonium sulphocyanate. 1 Cc. tenth-normal silver nitrate=0.007936 Gm. of bromine.

Actions and Uses.—Bromipin acts like the bromides, but as it yields its bromine more slowly it is thought to have less tendency to produce brominism. The combination is not broken up in the stomach, but a portion of the bromine is split off as soon as the oil enters the intestine. The oil with the remaining bromine is easily absorbed, and, similarly to other fats, is largely deposited in the tissues, where it is slowly split up. It is said to be more lasting in its action than the bromides.

Dosage.—1.3 Gm. (20 grains) of 33 1-3 per cent. bromipin or 4 Cc. (1 fluidram) of 10 per cent., which may be increased in cases of epilepsy to from 2.6 to 10.4 Gm. (40 to 160 grains) of 33 1-3 per cent. bromipin or from 8 to 32 Cc. (2 to 8 fluidrams) of 10 per cent. bromipin. The liquid may be given in emulsion with peppermint water and syrup, or pure, flavored with oil of peppermint.

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York.) U. S. patent No. 774.224 (Nov. 8, 1904; expires 1921). German patent No. 96.495.

Bromipin, 10 per cent.—Bromipin, 10 per cent. is a 10 per cent. brominized sesame oil.

Bromipin, 33⅓ per cent.—Bromipin, 33⅓ per cent. is a 33⅓ per cent. brominized sesame oil.

Capsules of Bromipin, 33⅓ per cent.—Each capsule contains bromipin 33⅓ per cent. 2 Gm. (30 grains).

Tablets of Bromipin, 33⅓ per cent.—Each tablet contains bromipin 33⅓ per cent. 1.2 Gm. (19 grains).

BROMO-MANGAN—Liquor Ferro-Mangani Bromopeptonati "Dieterich."—Bromo-mangan is Ferro-mangan Dieterich with the addition of 3 per cent. of bromopeptone. Bromopeptone contains 11 per cent. of bromine.

The process of preparation is the same as that given under Ferro-mangan "Dieterich" with the addition of a solution of bromopeptone.

Bromo-mangan is a clear dark brown liquid of agreeable odor and taste.

Method of Valuation: After determination of the percentage of iron and manganese, a test method should be employed as described by Dr. Karl Dieterich in Helfenberg Annals, 1901, pages 162-165, to ascertain the percentage of halogens in bromopeptone: About 0.5 bromopeptone should thoroughly mixed with a few grammes of a mixture of 1 part potassium nitrate and 2 parts sodium carbonate, either in a porcelain or platinum crucible. The mixture is then covered with a light layer of sodium carbonate, covered and carefully heated until reaction sets in. When finished a little potassium nitrate is added to obtain a smooth flux, then the molten mass is exposed to glowheat for about 15 minutes. After cooling the mass is dissolved in hot water, rinsed into a beaker, filtered, if necessary, acidulated with diluted acetic acid and bromate present reduced with sulphurous acid. The excess of acid is driven off by the heat, the liquid strongly acidulated with nitric acid, again heated, until the gas formation ceases, then precipitated while hot with silver nitrate. The silver bromide is collected on a weighed filter, washed with very dilute ammonia water, as the preparation contains hydrochloric acid, dried and weighed.

Actions and Uses.—Bromo-mangan is said to be a reconstructive tonic, blood-making adjuvant and a sedative.

It is claimed to be useful when anemia is associated with nervous disturbances, as in epilepsy, neurasthenia, hysteria, etc.

Manufactured by Chemische Fabrik Helfenberg A. G., near Dresden, Germany (Reinschild Chemical Co., New York). U. S. trademark No. 44,333.

BROMURAL. — Bromural (CH_3.CH(CH_3)CHBr.CO)HN.CO.NH_2 = $C_6H_{11}N_2O_2Br$, is 2-monobrom-isovaleryl-urea obtained by the interaction of urea with brom-isovaleryl bromide.

Bromural forms small, white, almost tasteless needles which are easily soluble in hot water, ether, alcohol and alkalies, but less readily in cold water. It sublimes on heating and melts in the neighborhood of 145° C. (293° F.).

Bromural can be precipitated from a 10 per cent. sodium hydroxide solution with acids. The presence of bromine may be demonstrated with fusion with sodium carbonate and potassium nitrate and testing for a bromide with silver nitrate solution. On heating the alcoholic solution of bromural with sodium ethylate for several hours on the water bath, sodium bromide will precipitate. If this be filtered off and the filtrate evaporated, a crystalline mass will remain which can be recrystallized from water. *This is dimethylacrylic acid*, melting at 280° C.

If 1 Gm. bromural be boiled for about 1 minute with 10 per cent. solution of sodium hydroxide, ammonia obtained from the urea will be given off.

If the hot liquid be then cooled, acidified with nitric acid and extracted with ether, and the ether evaporated an oily fluid, 1-brom-isolvaleric acid, which has the specific odor of valeric acid, will remain.

The biuret reaction cannot be obtained. On melting bromural and adding concentrated sodium hydroxide solution and copper sulphate, no color reaction will take place.

Actions and Uses.—Bromural is a nerve sedative which is claimed to produce sleep without markedly affecting the circulation or respiration. All action by bromural is said to cease after from three to five hours. In many cases, however, the sleep caused by the preparation continues beyond the limits of its action. It is claimed to be useful as a nerve sedative and for the purpose of inducing sleep in functional nervous diseases. Bromural does not produce the desired effects in cases of insomnia where pain, cough, angina pectoris and excitement or delirium exist.

Dosage.—As a nerve sedative 0.3 Gm. (5 grains) three times daily; as a specific at bedtime, 0.6 Gm. (10 grains), which dose may be repeated if needful during the night, after the action of the first dose has ceased.

Manufactured by Knoll & Co., Ludwigshafen a. Rh., Germany (Knoll & Co., New York. Merck & Co., New York). U. S. patent No. 914,518 (March 9, 1909; expires 1926). U. S. trademark No. 61,165. German patent No. 185,962.

Bromural Tablets, 5 grains.—Each tablet contains bromural 0.3 Gm. (5 grains).

BROVALOL.—Brovalol is bornyl brom-valerate, CH_3.CH(CH_3).CHBr.COO($C_{10}H_{17}$) = $C_{15}H_{25}O_2Br$, the brom-isovaleric-acid ester of borneol. It contains 25.2 per cent. bromine.

Brovalol is obtained by esterification of borneol with bromisovaleric acid or its derivatives.

Brovalol is a colorless, oily liquid, having a slight aromatic odor. Under 10 mm. pressure it boils at 163° C. (325.4° F.). It is insoluble in water but soluble in alcohol, chloroform and ether.

Action and Uses.—Brovalol acts as an analeptic, antispastic and nervine. It is claimed to be well tolerated even in large doses and to possess greater sedative power than similar valeric acid derivatives, due to its bromine content.

Dosage.—0.25 to 0.75 Gm. (4 to 12 grains) several times a day. It is supplied only in capsules (pearls), each containing 0.25 Gm. (4 grains).

Manufactured by Chemische Fabrik auf Actien vorm. E. Schering. Berlin, Germany (Schering & Glatz, New York). U. S. patent No. 930.054 (Aug. 3, 1909; expires 1926). U. S. trademark applied for.

BUTYL-CHLORAL HYDRATE—Butyl-Chloral Hydratum.—Trichlorbutylidene Glycol—Croton Chloral Hydrate—Butyl-Chloral Hydras (British Pharm., 1908). Butyl-chloral Hydrate is 2, 2, 3-trichlorbutan-1, 1,-di-ol, CH_3.CHCl.CCl_2.CH$(OH)_2$ = $C_4H_7O_2Cl_3$, a crystalline product obtained by the addition of water to the liquid butyl chloral (2, 2, 3,-trichlorbutan-ol, CH_3.CHCl.CCl_2.CHO).

Butyl-chloral hydrate occurs in pearly white, trimetric laminæ, having a pungent but not acrid odor, and an acrid, nauseous taste. It fuses at about 77.8° C. (172° F.) to a transparent liquid, which, in cooling, commences to solidify at about 71.1° C. (160° F.). It is soluble in about 50 parts of water, and its own weight of glycerin or of alcohol (90 per cent.); it slowly dissolves in 20 parts of chloroform. From a solution in alcohol it is precipitated by the gradual addition of water, in the form of globules said to consist of butyl chloral alcoholate $C_4H_5Cl_3O.C_2H_5OH$. The alcoholic solution is neutral and the aqueous solution neutral or but slightly acid to litmus. It gives no precipitate with test-solution of silver nitrate. It does not yield chloroform when heated with solution of potassium hydroxide or with milk of lime (absence of chloral hydrate).

Actions and Uses.—Its action is similar to that of chloral, except that it is said to be less depressing and more analgesic. It has been especially recommended for facial neuralgia.

Dosage.—0.3 to 1.3 Gm. (5 to 20 grains).

CALCIUM LACTATE—Calcii Lactas.—Calcium lactate, $Ca(C_3H_5O_3)_2.5H_2O$, is the calcium salt of lactic acid.

It is prepared in the manufacture of lactic acid by the lactic acid fermentation of sugar or by the neutralization of lactic acid by calcium carbonate.

It occurs in white crystalline masses or powder, odorless and tasteless. It is soluble in 9.5 parts of water, easily soluble in hot water. At 100° C. (212° F.) it loses water of crystallization.

If calcium lactate be heated gently with a mixture of sulphuric acid and potassium permanganate the odor of aldehyde will be given off. An aqueous solution of calcium lactate will throw down a white precipitate, insoluble in water and acetic acid, on the addition of a solution of ammonium oxalate.

Actions and Uses.—Calcium lactate has the pharmacologic action of other calcium salts. Being less irritating than the chloride, it may be given subcutaneously. It is used in the belief that it will increase the coagulability of the blood.

CALOMELOL—Hydrargyri Chloridum Mite Colloidale.—Colloidal Calomel.—Calomelol is a soluble colloidal form of calomel, containing albuminoids.

According to the patent it is prepared by acting on a solution of sodium chloride in presence of a proteid with mercurous nitrate and precipitating the water soluble colloidal calomel by means of alcohol. The precipitate is washed with alcohol, redissolved in water with the aid of a little alkali, and from this solution the colloidal calomel is obtained either by evaporation or by precipitation with alcohol.

It forms a white-gray, odorless and tasteless powder, containing 80 per cent. of mercurous chloride and 20 per cent. of proteids. It is soluble in water, forming an opalescent solution; insoluble in alcohol, ether and benzene. It is precipitated from its aqueous solutions by acids, the precipitate being redissolved by alkalies.

Actions and Uses.—Its action is the same as that of calomel but it is claimed to be superior because of its solubility in water, acting more rapidly and efficiently, and to be nonirritant and particularly non-toxic. The indications for its use are the same as for calomel.

Dosage.—Internally the same as calomel. Externally it is used as a dusting powder, mixed with an equal quantity of starch or of a mixture of starch and zinc oxide, or in the form of calomelol ointment. It should be guarded from the light.

Manufactured by the Heyden Chemical Works, New York. U. S. patent No. 740,835 (Oct. 6, 1902; expires 1920). U. S. trademark.

Calomelol Ointment.—Calomelol Ointment is an ointement containing 28 per cent. of mercury in the soluble form of calomelol (which see) and 2 per cent. in the insoluble form.

It is prepared by combining 45 parts of calomel with sufficient lard to make 100 parts.

Dosage.—6 Gm. (90 grains) daily for inunction in syphilis.

CARBOSANT.—Santalolis Carbonas.—Carbosant is santalyl carbonate, $CO(OC_{15}H_{23})_2 = C_{31}H_{46}O_3$, the carbonic acid ester of santalol.

Carbosant is produced by the chemical interaction of santalol with carbonyl chloride, $COCl_2$, and alkalies, or with carbonic acid esters.

Carbosant is an oily yellow fluid, almost tasteless and odorless, insoluble in water, and soluble in alcohol and ether. It contains 94 per cent. of santalol.

Carbosant is saponified when heated with an alcoholic solution of caustic alkali with the production of potassium carbonate and santalol, both of which can be identified by appropriate tests.

Actions and Uses.—The action of carbosant which is chemically broken up into its component parts in the intestine is identical with that of santalol, the active constituent of official sandal wood oil. It tends to diminish the secretions of the mucous membrane of the urinary tract, and to relieve pain in the urinary organs.

Carbosant is said to be useful in the treatment of gonorrhea, cystitis and prostatitis.

Dosage.—0.6 Cc. (10 minims) three times daily. It may be given in capsules, each containing 0.3 Gm. (5 grains), 2 capsules being given three times daily.

Manufactured by the Chemische Fabrik von Heyden at Radebeul near Dresden, Germany. (Heyden Chemical Works, New York.) German patent No. 182,627. Not patented in the United States. U. S. trademark applied for.

CEPHÆLINE—Cephælina.—Cephæline is an alkaloid, $C_{14}H_{20}NO_2$, obtained from ipecacuanha root.

Cephæline occurs as snow-white, fine, interlacing needles which readily turn yellow. It is soluble in ether and caustic soda solutions, melts at 96°-102° C. (204.8°-215.6° F.) and turns brown when heated to 120° C. (248° F.). With Fröhde's reagent, a freshly prepared solution of 0.1 Gm. sodium molybdate in 10 Cc. concentrated sulphuric acid, it gives a purple color which hydrochloric acid changes to prussian blue.

Actions and Uses.—These are identical with those of ipecac. It is relatively more emetic and less nauseant and causes relatively more renal irritation and less cardiac depression. It may be employed as an emetic and expectorant.

Dosage.—0.005 to 0.01 Gm. (1/12 to 1/6 grain) in pills or as a powder triturated with sugar of milk. The hydrochloride is soluble.

CHINOSOL.—Normal Oxychinolin Sulphate.—Chinosol is a normal oxychinolin sulphate $(C_9H_7ON)_2H_2SO_4$.

Chinosol is a yellow crystalline powder of saffron-like odor and burning taste. It melts at from 175° to 177.5° C. (347° to 351.5° F.). It dissolves readily in water but with difficulty in alcohol and it is insoluble in ether. The aqueous solution has an acid reaction.

A drop of solution of ferric chloride produces in a solution of chinosol a marked green coloration. Barium chloride produces a white precipitate. Solutions of alkaline hydroxides precipitate from an aqueous solution of chinosol a white precipitate, consisting of interlaced crystalline needles, which after filtration, washing and careful drying in a desiccator should melt at from 73° to 75° C. On incineration chinosol should not leave a weighable residue

Actions and Uses.—So far as experimental evidence goes, chinosol is nontoxic. It is a powerful antiseptic, slightly stronger in this respect than mercuric chloride and considerably stronger than phenol. It exerts an antiseptic action in solutions containing 1 part to 5,000. It is a feeble germicide being weaker than phenol and much weaker than mercuric chloride.

Dosage.—For internal use 0.3 Gm. (5 grains) three times daily. As an antiseptic the average strength of solution is 1 to 1,000; as a nasal or vaginal douche, the strength should be 1 part to 5,000, and as an eye-wash 1 to 8,000, gradually increasing the strength of the solution according to the sensitiveness of the patient.

Manufactured by Franz Fritzsche & Co., Hamburg, Germany (Chinosol Co., Parmele Pharmacal Co., New York). U. S. patent No 906,918 (Dec. 15, 1908; expires 1925). U. S. trademark No. 28,750.

CHLORALFORMAMIDE.

Chloralformamide is official in the United States Pharmacopeia. For description see the pharmacopeia or the Physicians' Manual of the Pharmacopeia and National Formulary.

CHLORALAMID.—A name applied to Chloralformamidum, U. S. P.

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin, Germany. (Schering & Glatz, New York). German patent No. 50,536; U. S. patents Nos. 429,039 and 429,040 (expired).

CHLORAL HYDRATE PREPARATIONS

ANTIPYRINE CHLORALHYDRATE—Antipyrinæ Chloralhydras.—Monochloral-Antipyrine.—Antipyrine Chloralhydrate, $C_{11}H_{12}N_2O.CCl_3CH(OH)_2 = C_{13}H_{15}N_2O_3Cl_3$, is antipyrine combined with one molecule of hydrated chloral.

It is prepared by triturating molecular proportions of antipyrine and hydrated chloral together, dissolving the resultant oily liquid in hot water and allowing the solution to cool.

It occurs in colorless octahedral crystals or a white crystalline powder, melting at 67° C. (152.6° F.). It is soluble in 10 to 11 parts of cold water, easily soluble in hot water, and in 3.5 parts of alcohol, forming neutral solutions.

The aqueous solution gives the usual reaction for antipyrine (a blood-red color with ferric chloride) and for hydrated chloral (turbidity and separation of chloroform when warmed with caustic alkali). Ammoniacal silver nitrate is reduced with the formation of a silver mirror, but the aqueous solution (1:10) acidified with nitric acid is not altered by silver nitrate nor precipitated by hydrogen sulphide. Antipyrine Chloralhydrate dissolves in concentrated sulphuric acid without coloration and leaves no weighable residue when incinerated on platinum.

It is incompatible with alkalies, their carbonates and bicarbonates and with metallic salts.

Actions and Uses.—Antipyrine Chloralhydrate is an analgesic and hypnotic resembling chloral in its action, but said to be less liable to produce injurious effects on the vasomotor center or the heart. It may be used where chloral is indicated, as in mild forms of mental excitement, incipient delirium tremens, and also in insomnia caused by pain.

Dosage.—1 to 2 Gm. (15 to 30 grains); although supposed to be less toxic than chloral, larger doses up to 3 Gm. (45 grains) should be used with caution. It may be given dissolved in water (1:10) flavored with syrup of orange or aromatic elixir.

Manufactured by Farbwerke, vorm. Meister, Lucius and Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York).

CHLORBUTANOL. — Trichlor-Tertiary-Butylalcohol — Acetone-Chloroform.—Chlorbutanol is 1,1,1-trichlor-2-methyl-*propan*-2-ol, $CCl_3.C(OH)\ (CH_3).CH_3 = C_4H_7OCl_3$, produced by the reaction of acetone on chloroform.

Made by the action of caustic alkalies on a mixture of chloroform and acetone. It is a white, crystalline, volatile compound having a camphoraceous odor and taste. It is soluble in water (8-1000), in fixed and volatile oils, and glycerin; very soluble in alcohol, ether, benzin, glacial acetic acid, chloroform and acetone.

Actions and Uses.—It is said to be absorbed unchanged from the alimentary tract, but to be decomposed in the body. It is a local anesthetic with an action weaker than that of cocaine, but sufficient frequently to prevent vomiting from gastric irritation. Its antiseptic action is said to be fifteen times as strong as that of boric acid. It acts on the central nervous system similarly to chloral, and although the claim has been made that hypnotic doses are without effect on the circulation and respiration independent observers have described a fall of blood pressure and interference with respiration in animals, and consider it fully as dangerous as chloral. In man 100 grains caused severe symptoms, but recovery occurred. It is claimed that no habit is induced, but this may be referable to its restricted employment. It is said to be useful as a mild local anesthetic in dentistry, etc., as a preservative for hypodermic solutions; for insomnia, vomiting, and for spasmodic conditions. It is also said to be useful as introductory to general anesthesia, lessening excitement and nausea.

Dosage.—0.3 to 1.5 Gm. (5 to 20 grains) dry or in capsules. Hypodermically as a local anesthetic a saturated aqueous solution may be used.

Proprietary Preparations:

CHLORETONE.—A name applied to chlorbutanol by Parke, Davis & Co., Detroit, Mich. U. S. trade-mark.

Chloretone Inhalant.—Chloretone (chlorbutanol), 1 Gm.; camphor, 2.5 Gm.; menthol, 2.5 Gm.; oil of cinnamon, 0.5 Gm.; refined liquid petroleum, 93.5 Gm.

Actions and Uses.—An anodyne, antiseptic, and emollient solution for use by inhalation as a very fine spray or nebula.

METHAFORM.—A name applied to chlorbutanol by F. Stearns & Co., Detroit, Mich. U. S. trade-mark.

CITARIN.—Sodium Anhydromethylene Citrate.

Citarin,  $= Na_2C_7H_6O_7$ is the normal sodium salt of anhydromethylene-citric acid.

Anhydromethylene-citric acid is obtained by reacting on citric acid with paraformaldehyde (German patent No. 129,255) or with chlormethyl alcohol, CH_2ClOH (German patent No. 150,949). The sodium salt is obtained by treating the acid with sodium hydroxide solution and precipitating the resulting salt with alcohol (U. S. patent No. 715,329).

It is a white, granular, somewhat hygroscopic powder, having a faintly saline and acidulous taste, and a slightly acid reaction. It is readily soluble in about 1.5 parts of water, but insoluble in alcohol. Its solutions split off formaldehyde when heated, particularly in the presence of alkalies, and mineral acids separate from its concentrated solutions methylenecitric acid.

Formaldehyde can be demonstrated by means of Jorrisson's reaction, or by sodium nitrite and sulphuric acid, or by silver nitrate and soda solution.

It is incompatible with acids and alkalies and is decomposed by heat.

Actions and Uses.—This is one of the compounds which it is claimed increase the elimination of uric acid by forming very soluble compounds with that substance. It is claimed to be useful for gout and chronic rheumatism

Dosage.—1 to 2 Gm. (15 to 30 grains), largely diluted with water.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 715,239 (Dec. 2, 1902; expires 1919).

Citarin Tablets, 15 grains.—Each tablet contains citarin 0.97 Gm. (15 grains).

COLLARGOL — Collargolum.— Colloidal Silver — Argentum Colloidale—Argentum Credé.—Collargol is a water-soluble, allotropic form of metallic silver, said to contain 85-87 per cent. of silver, and a small percentage of albumin with products of its oxidation.

Collargol occurs as small, hard, brittle, bluish-black, scale-like pieces. It is soluble in 20 parts of distilled water, producing a dark olive-brown solution which remains stable for months. No separate silver particles can be distinguished in the solution even when magnified to the highest degree under the microscope, and it has all the other characteristics of a solution. The addition of albumin to collargol prevents or delays its precipitation by acids and salts. A sufficient amount of albumin to prevent its precipitation under ordinary conditions is therefore added to collargol during its manufacture. Hence collargol, even when dissolved in spring or well water containing salts, undergoes no change, and it remains unaffected by boiling, whereas colloidal silver, containing no albumin, precipitates on being boiled.

A solution of collargol does not respond directly to the usual tests for silver. If the solution is warmed with nitric acid a white cloudiness is produced, which clears completely on standing and the silver can then be demonstrated in the usual manner. On heating a fragment of collargol on a platinum scoop, shining white metallic silver of the ordinary kind, insoluble in water, is at once formed.

Its solution should not be exposed to light or air; it is incompatible with the usual silver reagents.

Actions and Uses.—Collargol is claimed to be a systemic antiseptic and germicide.

Dosage.—In most cases it is best employed locally in the form of a 15 per cent. ointment (see Collargol ointment), 2 to 4 Gm. (30 to 60 grains) being very thoroughly rubbed into the skin; otherwise, in carefully filtered solutions, varying in strength according to the intended use; 2 per cent. to 5 per cent. for intravenous injections, 1/50 per cent. to 1 per cent. solutions for washes; 5 per cent. dusting powder, prepared with finest clay; in the form of bougies containing 0.2 Gm. (3 grains), and vaginal suppositories and tampons each containing 0.05 Gm. (¾ grain), for parenchymatous injections in 0.5 per cent. to 1 per cent. glycerin solutions. Internally a solution of 1:500 to 1:100 is given freely in teaspoonful doses added to the food, in infectious gastric and intestinal diseases. It is also given in tablets containing 0.06 Gm. (1 grain).

Manufactured by the Heyden Chemical Works, Radebeul, Germany, and Garfield, N. J. (Schering & Glatz, New York). U. S. trademark No. 32,452.

Collargol Ointment—Unguentum Credé.—Ointment of Colloidal Silver.—Collargol Ointment is an ointment containing 15 per cent. of collargol.

It is prepared by incorporating 15 parts of collargol with 5 parts of water, 10 parts of white wax, and 70 parts of benzoinated lard, observing care that the soluble silver shall not be transformed into metallic silver of the ordinary kind. This, it is asserted, it is prone to do unless great care is observed in the manipulation.

The natural color of collargol ointment is dark bluish-gray. The addition of water may impart to the ointment a brownish shade; this does not, however, in any way impair its efficiency. The ointment is good as long as it colors the skin black.

CONIINE HYDROBROMIDE—Coniinæ Hydrobromidum.—Coniine hydrobromide is the hydrobromide, $C_8H_{17}N.HBr$, of an alkaloid found in conium.

Coniine hydrobromide occurs as colorless, transparent, glistening rhombic crystals, or as a white crystalline powder, melting at 210-214° C. (410-417° F.). It is soluble in two parts of water, in three parts of alcohol, and in ether-alcohol, but insoluble in ether. The solutions are colorless and neutral. The salt contains 61.09 per cent. of coniine.

Evaporated with an excess of sulphuric acid, coniine hydrobromide becomes red, violet, blue and finally brown. An aqueous solution of the salt mixed with magnesium carbonate or oxide, and shaken with carbon bisulphide, colors the latter yellow. Addition of silver nitrate solution to a solution of coniine hydrobromide causes precipitation of yellow silver bromide; iodine test solution precipitates a reddish-brown body and tannic acid a yellowish-white compound. Coniine hydrobromide should burn when ignited, leaving no residue.

Actions and Uses.—Coniine hydrobromide paralyzes the peripheral endings of the motor nerves, producing an ever-increasing muscular weakness. To a less degree it affects the sensory nerves. With lethal doses consciousness is retained to the last. It probably depresses the spinal cord feebly and usually dilates the pupils. In therapeutic doses it is said to increase the temperature but in lethal doses it lowers it; convulsions may appear and death results from paralysis of respiration.

Coniine hydrobromide may be used for the same purpose as conium. It has been tried in chorea, paralysis agitans, whooping cough, and is said to produce a condition of calm and relaxation in maniacal and hysterical excitement. It is a dangerous remedy.

Dosage.—0.001-0.003 Gm. (1/60 to 1/20 grain) three times a day. Maximum single dose 0.005 Gm. (1/12 grain); maximum daily dose 0.015 Gm. (¼ grain). For hypodermic use a 5 per cent. solution is used.

COPPER CITRATE.—Cuprum Citricum.—Cupric Citrate.—Copper citrate is the cupric salt of citric acid, containing 34 to 36 per cent. of copper.

It occurs as a green, or bluish-green, finely crystalline, odorless powder. It is but slightly soluble in cold water. Somewhat more soluble in a cold solution of an alkali citrate, forming a greenish blue solution. More soluble in a hot solution of an alkali citrate; also soluble in ammonia water and in mineral acids.

When dissolved in ammonia water copper citrate yields an intense blue solution.

When heated to 90° C. (194° F.) the salt loses water of hydration and assumes a pale blue color. At higher temperature it blackens and at a low red heat leaves a black residue of cupric oxide.

Copper citrate should contain copper equivalent to from 34 to 36 per cent. of metallic copper.

If about 1 Gm. of copper citrate be dissolved in 20 Cc. of diluted hydrochloric acid, the solution diluted to 200 Cc. with hot distilled water, the mixture saturated with hydrogen sulphide, filtered, and the filtrate evaporated nearly to dryness on the water bath, the residue should respond to the usual tests for *citric acid.*

If 0.5 Gm. of copper citrate be dissolved in 10 Cc. of diluted hydrochloric acid and 1 Cc. of barium chloride test solution be added no turbidity should at once occur (limit of sulphate).

A solution of 0.5 Gm. of the salt in 10 Cc. of diluted sulphuric acid should not evolve any odor of acetic acid when boiled.

The salt should be free from nitrates, chlorides and carbonates.

Actions, Uses and Dosage.—Copper citrate possesses the astringent and antiseptic properties of other salts of copper somewhat modified by its sparing solubility.

It may be used for the same purposes and in doses similar to those of other salts of copper.

Non-Proprietary Preparations:

Copper Citrate, Mallinckrodt.—Manufactured by the Mallinckrodt Chemical Works, St. Louis, Mo.

Copper Citrate Ointment, 5 per cent., M. E. S. Co.—An ointment containing 5 per cent. of copper citrate and 95 per cent. of white petrolatum, without alcohol or preservative. Manufactured by the Manhattan Eye Salve Co., Owensboro, Ky.

Copper Citrate Ointment, 10 per cent., M. E. S. Co.—An ointment containing 10 per cent. of copper citrate and 90 per cent. of white petrolatum, without alcohol or preservative. *Manufactured by the* Manhattan Eye Salve Co., Owensboro, Ky.

CORYFIN.—Ethylglycolic Acid Ester of Menthol.—Coryfin is menthyl ethylglycolate, $CH_2(O.C_2H_5).COO(C_{10}H_{19}) = C_{14}H_{26}O_3$, the ethylglycolic acid ester of menthol.

It is prepared by the action of ethyloxyacetyl chloride on menthol. Coryfin is a limpid, colorless oil, having a very faint menthol odor. It boils under 20 mm. pressure at about 155° C. (311° F.) and is soluble in alcohol, ether and chloroform; difficultly soluble in water.

When heated with caustic alkalies it is split up into menthol and *ethylglycolic acid.* When incinerated on platinum foil it leaves no residue. Aqueous solutions must not have an acid reaction and must be free from chlorine and sulphuric acid.

Actions and Uses.—Soon after its application to the skin or mucous membranes a cooling effect is produced, said to be due to the splitting off of menthol, to which the pharmacologic actions of the remedy are to be ascribed.

Coryfin is said to be useful as a substitute for menthol in nervous headaches, coryza and conditions of hoarseness and pharyngeal irritation.

Dosage.—In headache it may be lightly rubbed in or painted on the forehead, avoiding contact with the eyes; in coryza it may be applied to the mucous membrane with a brush or as a spray. In throat affections a few drops (3 or 4) may be placed on a lump of sugar and allowed to dissolve in the mouth, or mixed with tepid water and used as a gargle.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 836,914 (Nov. 27, 1906; expires 1923). U. S. trademark No. 43,416.

COTARNINE HYDROCHLORIDE—Cotarninæ Hydrochloridum.—Cotarnine Hydrochloride. $C_{12}H_{13}O_3N.HCl$, is the cotarnine salt of hydrochloric acid. Cotarnine is an oxidation product of narcotine, similar to hydrastinine.

It is prepared by boiling narcotine for a long time with water or by heating it with dilute nitric acid and converting the basic product obtained into the hydrochloride.

It is a yellow, crystalline powder, soluble in water and in alcohol. Its melting point is indefinite.

If to a solution of cotarnine hydrochloride tenth-normal iodine V. S. is added, a brown precipitate of coatrnine periodide is produced, which if collected and dried over sulphuric acid melts at 140° C. (284° F.).

If to a solution of 0.1 Gm. cotarnine hydrochloride in 2 Cc. of water 3 drops of a 15 per cent. sodium hydroxide solution are added, each drop will produce a milk-white precipitate which dissolves on agitation After a time the free base separates from the clear solution, leaving the supernatant liquid clear and but faintly yellow. The base, after recrystallization from benzene, melts, with decomposition, at 130° C. (266° to 269.6° F.).

Actions and Uses.—Cotarnine hydrochloride is a hemostatic, analgesic and uterine sedative. The mechanism of its action is obscure.

It is said to be useful particularly in functional dysmenorrhea of puberty and of the climacteric; in subinvolution of the uterus after parturition and abortion, as well as in all profuse uterine hemorrhages; in bleeding from the bladder, from the nose, after extraction of teeth, etc.

Dosage.—Internally 0.05 Gm. (¾ grain) four to five times daily. Because of its intensely bitter taste, it is best given in the form of coated tablets, pills, or capsules; or by hypodermic injection (in urgent cases) 2 Cc. of a 10 per cent. solution; externally, as a styptic, pure or in strong solution.

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York).

COTARNINE PHTHALATE—Cotarninæ Phthalas.—Cotarnine phthalate $(C_{12}H_{13}O_3N)_2C_6H_4(COOH)_2$, is the cotarnine salt of phthalic acid.

The base cotarnine, obtained from narcotine by oxidation with dilute nitric acid, *is combined with phthalic* acid to form the neutral *salt.*

It is a yellow, microcrystalline powder, easily soluble in water. The base is recognized by the tests given under cotarnine hydrochloride.

Actions and Uses.—Cotarnine phthalate is said to have hemostatic and pronounced sedative properties. Its modus operandi is unknown. Its action resembles that of *cotarnine* hydrochloride, but phthalic acid compounds have especial hemostatic properties. Cotarnine phthalate is said to be useful in uterine hemorrhage.

Dosage.—Internally in sugar-coated tablets of ¾ grain each, 3 to 5 tablets a day (up to 9 tablets a day in cases of dysmenorrhea). Locally as a dusting powder. By subcutaneous injection (3 grains dissolved in 30 minims of water) for quick arrest of severe hemorrhage.

Manufactured by Knoll & Co., Ludwigshafen a. Rh., Germany, and New York. U. S. patent No. 742,532 (Oct. 27, 1903; expires 1920).

CREOSOTE CARBONATE.—Creosote Carbonate is a mixture of carbonic acid esters, analogous to guaiacol carbonate, prepared from creosote.

It is prepared by passing a current of carbonyl chloride into a solution of creosote in sodium *hydroxide, and purifying* the oily product by washing with weak soda solution and with water.

It is a yellowish, thick, honey-like, perfectly clear and transparent liquid, containing 92 per cent. *of creosote.* It is odorless and has a bland oily taste. It is insoluble in water, but soluble in alcohol, ether, chloroform, benzene and in fixed oils.

The addition of a few drops *of ferric* chloride solution to the alcoholic solution should not cause any change in color. On boiling with potassium hydroxide *solution* the odor of creosote is evolved.

It is incompatible with alkalies.

Actions and Uses.—Creosote Carbonate has the same *action* as creosote, but is claimed to be non-toxic *and devoid* of irritant properties. It is recommended as a substitute for creosote for internal exhibition in tuberculosis, pneumonia, and as an intestinal antiseptic.

NOTE: The Council would note that any *claims* of non-toxicity that are made for drugs that have or are supposed to have important general effects are admitted *to this* book only when they do not conflict with known facts. In all such instances, however, it is recommended that a lack of toxicity be not accepted too freely but be *considered* to mean only that toxic effects have *not* as yet been recognized with the doses that have been studied. The most sincere and apparently justified beliefs concerning this point are often ultimately *reversed by* extended experience. Much the same may be said regarding any claims that drugs are non-irritating.

Dosage.—From 0.3 to 2.0 Gm. (5 to 30 grains) for children, to 1 to 4 Gm. (15 to 60 grains) for adults *in milk, coffee,* wine, cod-liver oil or emulsion. Externally it may be applied undiluted.

Proprietary Preparations:

CREOSOTAL.—A name applied to Creosote Carbonate.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 501,235 (expired) ; U. S. trademark.

CREOSOTAL-Heyden.—A name applied to Creosote Carbonate.

Manufactured by Fabrik von Heyden, Radebeul, near Dresden, Germany (Schering & Glatz, New York). U. S. patent No. 501,235 (expired). U. S. trademark.

DIASPIRIN.—Diaspirin is succinyl disalicylic acid, $CO(O.C_6H_4.COOH).CH_2.CH_2.CO(O.C_6H_4.COOH)$.

Diaspirin is a salicylic acid derivative, produced by the interaction of the two carboxyl groups of succinic acid with the phenolic hydroxyls of two molecules of salicylic acid, with the elimination of 2 molecules of water, *thus:* $COOH.CH_2.CH_2.COOH + 2HO.C_6H_4.COOH = CO(O.C_6H_4.COOH).CH_2.CH_2.CO(O.C_6H_4.COOH) + 2H_2O$.

It is prepared by the action of succinyl dichloride upon salicylic acid.

Diaspirin is an odorless and almost tasteless white crystalline powder, said to melt at about 178° C. (352.4 F.) (Specimens examined by the Council were found to melt at 168° C. Corr.) Soluble with difficulty in cold alcohol and glacial acetic acid; scarcely soluble in water. By heating with caustic alkalies it decomposes into succinate and salicylate. Diaspirin is a dibasic acid which reacts with bases, organic or inorganic, to form salts.

Diaspirin produces the effects of salicylates. The following special claims are made for it: That it passes unchanged through the stomach, producing no irritation, but is split into its constituents in the intestine; that it exerts a strong diaphoretic effect.

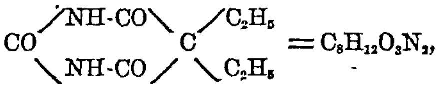
Actions and Uses.—The same as those for salicylic acid.

Dosage.—1 Gm. (15 grains) three or four times daily.

Manufactured by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany. (Farbenfabriken, of Elberfeld Co., New York). U. S. patent No. 874,929 (Dec. 31, 1907; expires 1924). U. S. trademark applied for.

DIETHYL-BARBITURIC ACID AND COMPOUNDS

VERONAL — Veronalum. — Acidum diæthyl-barbituricum. Diethyl malonyl urea. Malo-urea. Veronal is diethyl-barbituric acid, 2, 4, 6-trioxy-5-diethyl pyramidin.



$$CO\langle{NH\text{-}CO \atop NH\text{-}CO}\rangle C \langle{C_2H_5 \atop C_2H_5} = C_8H_{12}O_3N_2,$$

a ureide derived from diethylmalonic acid, $COOH.C(C_2H_5)_2.COOH$, and urea, $CO(NH_2)_2$.

It may be prepared by the interaction of esters of diethylmalonic *acid with urea in the presence* of metallic alcoholates. (U. S. patent No. 782,739.). It is also obtained by condensation of diethylcyanacetic ester with urea by means of sodium alcoholate.

It is a white, crystalline powder, melting at about 188° C. (370.4° F.), *odorless and* faintly bitter. It is soluble in about 150 parts of cold water, and in about 12 parts of boiling water. It is quite soluble in ether, acetone and ethyl acetate; also slightly soluble in chloroform, petroleum benzin, acetic acid and amyl alcohol. It *forms* salts with alkalies which are soluble in water.

Prolonged heating with sodium carbonate solution liberates ammonia. Denninges' reagent produces a white precipitate; Millon's reagent produces in solution acidulated with nitric acid a precipitate soluble in an excess of the reagent.

Actions and Uses.—Diethyl-barbituric acid is quickly absorbed, especially when it is given in solution. In small doses it induces sleep apparently without any other effect. In larger doses the temperature falls and animals show marked trembling and restlessness in their sleep. In small doses it is a relatively safe hypnotic, but fatalities have followed its indiscriminate use.

It is used in simple insomnia, as well as in that accompanying hysteria, neurasthenia and mental disturbances.

Dosage.—0.3 to 1 Gm. (5 to 15 grains) in hot water, tea or milk, or, if in wafers or capsules, followed by a cupful of some warm liquid.

Manufactured by Farbenfabriken, vorm. Friedr, Bayer & Co., Elberfeld. Germany, and E. Merck, Darmstadt. Germany. (Farbenfabriken of Elberfeld Co., New York, and Merck & Co., New York.) U. S. patent No. 782.739 (Feb. 14. 1905: expires 1922). U. S. trademark.

Veronal Tablets, 5 grains.—Each tablet contains veronal 0.33 Gm. (5 grains).

SODIUM DIETHYL-BARBITURATE.—Sodii Diæthyl-barbituras.—Sodium diethylbarbiturate, Na $(C_8H_{11}O_3N_2)$ is the mono-sodium salt of diethyl-barbituric acid.

Sodium diethyl-barbiturate occurs as a white, crystalline powder, soluble in 5 parts of water at 15° C. and in about 2 parts of boiling water. The aqueous solution of the salt has a bitter alkaline taste.

The salt contains 11.18 per cent. sodium (Na) and should yield about 89 *per cent.* (theory requires 89.31 per cent.) diethyl-barbituric *acid* (JOURNAL, Jan. 23, 1909, vol. 52, p. 311).

Action and Uses.—The same as diethyl-barbituric acid, but claimed to act more rapidly on account of its greater solubility. Because of its solubility, administration by rectal injection and also subcutaneous injection has been proposed.

Dosage.—The same as diethyl-barbituric acid, which see. It should be administered in aqueous solution.

Proprietary Preparations:

MEDINAL.—Medinal is a name applied to sodium diethylbarbiturate.

Manufactured by Chemische Fabrik auf Actien vorm E. Schering, Berlin, Germany (Schering & Glatz, New York). U. S. patent No. 780,241 (Jan. 17, 1905; expires 1922); 879,499 (Feb. 18, 1908; expires 1925). U. S. trademark applied for.

Medinal Suppositories, 7½ grains. Each suppository contains medinal 0.5 Gm. (7½ grains) incorporated with oil of theobroma.

Medinal Tablets, 5 grains.—Each tablet contains medinal 0.33 Gm. (5 grains).

VERONAL-SODIUM.—Veronal-sodium is a name applied to sodium diethyl barbiturate.

Manufactured by Farbenfabriken, vorm,. Friedr. Bayer & Co., Elberfeld, Germany, and E. Merck, Darmstadt, Germany. (Farbenfabriken of Elberfeld Co., New York, and Merck & Co., New York). *U. S. patent and trademark. (See Veronal.)*

Veronal-Sodium Tablets, 5 grains.—Each tablet contains veronal-sodium 0.32 Gm. (5 grains).

Prepared by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany. (Farbenfabriken of Elberfeld Co., New York.)

DIGESTIVE FERMENTS.

Valuation of Ferments: Qualitative tests for the activity of ferments can be easily applied, but such qualitative results have very little importance. Quantitative results also are important only in so far as they permit comparison with other ferments; and for this purpose the minutest details of the methods must be accurately observed. After investigation, the Council has decided to employ the following quantitative methods in its work:

1. *Amylolytic Power:* (For diastases, malt and pancreas preparations.) The Council does not approve the methods which are based on the time of change from blue to red color given by iodin; or the time of disappearance of all color; but instead it has adopted as the standard the amount of starch that can be converted to colorless end point in 10 minutes, by a given weight of the product, working according to the details described. (THE JOURNAL A. M. A., July 11, 1908, p. 140, and Journal Am. Chem. Soc., 1908, Vol. 30, p. 798.)

2. *Proteolytic Power in Alkaline Media:* (For trypsin and pancreatic preparations.) The approved methods are based on the quantity of fresh fibrin or coagulated egg albumen, which is dissolved by a given weight of the substance, in a slightly alkaline medium and in a given time.

3. *Proteolytic Power in Acid Media:* (For pepsin and gastric preparations.) This is determined by the U. S. P. method.

4. *Milk-Curdling Power:* (For rennet and gastric preparations.) The method is based on the quantity required to coagulate 100 Cc. of milk.

Incompatibilities: Ferments are more or less rapidly destroyed by boiling, by alcohol, by many salts, by unsuitable reaction of vehicle, by putrefaction, and by proteolytic digestion. Solutions of ferments tend to deteriorate on keeping.

Ferments are generally destroyed by each other, and also during their sojourn in the stomach; little therapeutic action can be secured beyond this organ, at least under ordinary conditions.

Therapeutic Indications.—The digestive ferments are used outside the body to predigest food. They are often applied locally for the softening of dead tissues or the solution of false membranes. They are administered internally for the purpose of supplementing or replacing deficient or absent normal secretions. In such cases they should be administered in such manner and at such times as to secure the most favorable conditions for their action. Diastases should be given with the food or before the stomach becomes highly acid. Trypsin and other ferments which are to act in the intestine should be given near the end of gastric digestion with sufficient alkali to neutralize the acid of the gastric juice. There is little if any reliable evidence that these latter ferments have any activity except in cases in which hydrochloric acid is absent from the stomach contents. In cases which present a total or nearly total lack of acid in the stomach they may be given with alkali at meal time or soon after the meal is *taken.*

Pancreatic Preparations.

DIAZYME ESSENCE.—A liquid stated to contain the amylolytic enzyme of the pancreas, devoid of trypsin and lipase in a menstruum containing 18.5 per cent. of alcohol by volume.

Diazyme essence is an amber fluid of aromatic taste and odor and slightly acid reaction.

One Cc. will convert 200 Gm. of pure starch mucilage, containing 8 Gm. of dry starch, the mixture being kept at 40° C., so that the solution will cease to give a color reaction with iodine at the end of ten minutes.

Actions and Uses.—Diazyme is capable of digesting starch and is claimed to be useful to compensate for deficient salivary and pancreatic action in the digestion of starch.

Dosage.—4 to 8 Cc. (1 to 2 fluidrams).

Manufactured by Fairchild Bros. & Foster, New York. U. S. trademark No. 44,878.

DIAZYME GLYCEROLE.—A liquid stated to contain the amylolytic enzyme of the pancreas, devoid of trypsin and lipase, in a menstruum containing about 60 per cent. of glycerin by volume.

It is a dense amber fluid, of agreeable taste and odor, and of slightly acid reaction.

One Cc. will convert at 40° C. 200 Gm. of pure starch mucilage, containing 8 Gm. dry starch, so that the solution will cease to give a color reaction with iodin in 10 minutes.

Actions, Uses and Dosage.—See Diazmye Essence.

Manufactured by Fairchild Bros. & Foster, New York. U. S. trademark No. 44,878.

GLYCEROLE TRYPSIN-Armour.—Glycerole trypsin is a 70 per cent. glycerin solution containing approximately 5 per cent. of trypsin powder.

Glycerole trypsin-Armour is prepared directly from the fresh pancreas of the hog.

It is a yellowish to brownish clear liquid of sweetish taste and peculiar characteristic color. Its incompatibilities are the same as those of trypsin. It should be kept in a cool place.

The strength of glycerole trypsin is tested in the same way as that of trypsin, using 3 to 5 Cc. of glycerole trypsin for 10 Gm. of moist blood fibrin.

Actions and Uses.—It is intended for internal and hypodermic use in the treatment of cancer.

Dosage.—Internally 4 to 8 Cc. (1 to 2 fluidrams) three times daily. Hypodermically 0.3 Cc. (5 minims) every other day, gradually increased, depending on the patient. This dose should be diluted with two or three volumes of sterile normal salt solution, using aseptic precautions and employing some local anesthetic.

Manufactured by Armour & Co., Chicago.

HOLADIN—Extractum Pancreaticum Integrum.—An extract of the entire pancreas containing all the constituents of the gland and exhibiting great potency in respect to the several known enzymes, trypsin, amylopsin, lipase and the milk-curdling ferment.

Holadin is a grayish-white powder, slightly aromatized, somewhat hygroscopic, freely but not wholly soluble in water.

Tests.—The tryptic power is tested as follows: 0.10 Gm. is placed in a flask, mixed by agitation with 25 Cc. of tepid water containing 0.20 Gm. sodium bicarbonate; at once 100 Cc. of milk at 40° C. is added, and then the flask kept in a water bath at 40° C. From time to time small portions are withdrawn in a beaker glass, when the addition of a few drops of dilute acetic acid will show a constant diminution in the volume and character of the curd until finally only minute, flocculent coagula are observed. Holadin should not remain in contact with sodium bicarbonate for more than a brief interval before adding the milk, as its enzymic power is rapidly decreased thereby.

To test for the fat splitting action, 0.10 Gm. of holadin is mixed with 25 Cc. of water and 100 Cc. of milk and maintained at 40° C. In about 15 minutes the presence of fatty acids can be detected by odor and taste and confirmed by chemical tests.

The action of the milk-curdling ferment is shown in the following way: 0.02 Gm. holadin is mixed with 10 Cc. water in a beaker and then 100 Cc. fresh milk, previously warmed to 40° C., poured on, with sufficient stirring to mix thoroughly, and the mixture digested, without agitation, in a water bath at 40° C. In a few minutes the milk will begin to show the characteristic evidences of curdling similar to that produced by the milk-curdling ferment of the gastric juice. When the milk, however, has acquired a semi-solid, jelly-like consistency, if it then be stirred constantly with a glass rod, the curd will break down, become diffusible and in time disappear, a behavior which is in marked contrast to the action of the milk-curdling ferment of the gastric juice which causes the formation of a firm curd, easily separable from the whey.

The starch-converting power is determined as follows: Triturate 15 Gm. of arrowroot or potato starch with 500 Cc. of distilled water, boil for 10 minutes, allow to cool, and make up to 500 Cc. with distilled water. Prepare an iodin test solution by diluting 0.5 Cc. of Liquor Iodi Compositus, U. S. P., with water to make 500 Cc. and have ready sufficient number of tubes containing an equal quantity of this solution.

Triturate 0.130 Gm. holadin in a perfectly dry mortar with 1.170 Gm. of lactose. Place 100 Gm. of the starch mucilage in a Florence flask in a water bath at 40° C. and mark "A"; place in the water bath also another flask of the same content and mark "B." Add to flask "A" 0.20 Gm. of the holadin triturate; to flask "B" add 0.05 Gm. of the holadin triturate; maintain both flasks in the water bath at 40° C. At the expiration of ten minutes withdraw from flask "A" one drop of the solution and add to one of the tubes of the iodine solution, when no coloration will occur. At the end of fifty minutes take one drop from flask "B" and add to one of the tubes of iodine solution, and at intervals of a few minutes repeat this; in about sixty minutes, no coloration, or at the most a very faint coloration, will appear. Under these circumstances, one grain of holadin will convert 135 grains of starch completely in ten minutes, and 600 grains in about sixty minutes.

Actions and Uses.—Holadin has power to digest starch and proteids and to split fats. It is claimed to be useful in various diseases in which digestion of food is imperfect.

Dosage.—Holadin is furnished only in capsules, each capsule containing approximately three grains. One capsule should be given about three hours after meals and one capsule at bedtime. The dose can be gradually increased to two or three capsules at a time.

Manufactured by Fairchild Bros. & Foster, New York. U. S. trademark No. 60,625.

Holadin and Bile Salts, Fairchild.—This preparation is a mixture of Holadin 5 parts with Bile Salts, Fairchild (which see) 1 part, put up in 3 grain capsules, containing holadin approximately 0.15 Gm. (2½ grains), and bile salts 0.03 Gm. (½ grain).

Dosage.—One capsule about three hours after meals and one capsule at bedtime.

PANASE.—Panase is a combination of the digestive enzymes of the pancreas derived from the pancreatic gland of the pig.

It is prepared by macerating the gland and extracting the enzymes together with a small amount of the proteid matter of the gland.

Panase is a light, yellowish white powder having a slight odor and somewhat mucilaginous taste. It is not entirely soluble in water or glycerin, owing to the small amount of protein present. Filtration of its solution, however, does not impair its digestive activity.

It is incompatible with strong alcohol, acids, alkalies, and other substances which destroy the activity of ferments.

Panase should possess the diastasic, proteolytic, milk curdling, and fat splitting properties of the pancreatic juice. It converts 200 times its weight of hydrous starch to loss of blue iodine reaction in ten minutes when tested according to the method of Blome (Pharm. Rev., 1906, vol. 24, p. 260). According to the method adopted by the Council it converts 113 parts of anhydrous starch to the colorless end point in ten minutes (Journal A. M. A., July 11, 1908, p. 140; Jour. Am. Chem. Soc., May, 1908, p. 798). For the methods of testing for the different enzymes see Pancreatic Preparations.

Actions and Uses.—Panase is intended to be used in cases in which it is believed that the enzymes of the pancreas are deficient or in which it is desired to hasten the digestion of starch.

Dosage.—0.13 Gm. (2 grains) or more.

Manufactured by Frederick Stearns & Co., Detroit, Mich.

Panase Essence.—Essentia Panasi. A mixture containing in each 100 Cc., 4 Gm. of panase in a menstruum containing 14 per cent. of alcohol and 12.5 per cent. of glycerin with small amount of flavoring matter and sugar. Dose 4 Cc. (1 fluidram) containing 0.16 Gm. (2¾ grains) of panase.

Panase Tablets.—Each tablet contains panase, 0.13 Gm. (2 grains).

TRYPSIN-Armour.—Trypsin is the proteolytic ferment of the pancreas.

Trypsin-Armour is prepared from the fresh pancreas of hogs with the view of retaining the proteolytic ferment in an especially active condition. It has been activated by enterokinase

It is a light yellow powder, possessing a faint odor and a meat-like taste. It is not completely soluble in water at once, but dissolves almost entirely in time. It is insoluble in alcohol and ether. Free acids (in more than traces), pepsin and large amounts of alkalies are incompatible. Solutions of trypsin should not be exposed to a temperature above 40.6° C. (105° F.).

The proteolytic power of trypsin is determined by digesting 10 grams of fresh moist blood fibrin in 50 Cc. of solution of sodium carbonate, 0.4 per cent., to which has been added 0.150 to 0.300 Gm. of the trypsin powder, maintaining the mixture at 40° C. (104° F.) for one hour, and shaking by rotation every ten minutes. The fibrin used is washed free from blood with cold water and then chopped, using an Enterprise meat chopper with plate having 5/64 inch perforations. The hashed fibrin is pressed lightly in a cloth, mixed, and is then ready for use. The residue left after one hour's digestion is compared with the amount left by employing a standard sample of trypsin powder under exactly the same conditions at the same time.

Actions and Uses.—Trypsin has the power of digesting proteid materials; it acts best at 40° C. (104° F.) and in a slightly alkaline medium.

When applied locally in solutions made slightly alkaline by sodium carbonate, it dissolves diphtheritic and other false membranes. It is claimed to have the power of destroying the cells of cancer without acting on the healthy tissue. These claims, however, are not generally accepted.

Dosage.—Trypsin is applied locally by means of a brush or as a spray. About 0.4 Gm. (6 grains) are mixed with 0.13 Gm. (2 grains) sodium bicarbonate and triturated in a mortar while adding 1 or 2 drams of distilled water, then warmed to 38° to 40.6° C. (100° to 105° F.) and applied immediately. The application may be repeated several times an hour if necessary, a fresh solution being made before each application. The internal dose is 0.13 Gm. (2 grains) or more three times daily. It should not be used for hypodermic injection.

Manufactured by Armour & Co., Chicago.

Milk Curdling Ferments.

PEGNIN—Milk Sugar Rennet.—The milk-curdling enzyme of calf's rennet, diluted with sugar of milk and sodium chloride.

Pegnin is prepared by mixing pure rennin with milk sugar and sodium chloride.

It is a fine white powder, having a sweet, saline taste, readily soluble in water, and forming a solution which readily and rapidly coagulates the casein of milk.

On adding 2 Gm. of pegnin to 200 Gm. of milk, which has been boiled and cooled to 40° C. (104° F.), and shaking the mixture, the milk should be completely coagulated in from 3 to 4 minutes, and after vigorously shaking the curd should be finely divided and equally distributed throughout the liquid. A solution of 1 Gm. of pegnin in 50 Cc. of water should require 17 to 17.5 Cc. of tenth-normal silver nitrate for complete precipitation, equivalent to 10 per cent. sodium chloride.

It is incompatible with a temperature higher than that indicated for the fermentative action.

Actions and Uses.—Producing a finely divided coagulum, it obviates the formation of the clotty curds which are liable to be produced when untreated cow's milk is taken as food. Cow's milk coagulated with pegnin as described below has been used for infant feeding and as a food for adults in stomach affections and in disturbances of the digestion incident to infectious diseases, in hyperacidity, etc.

Dosage.—8 to 10 Gm. (120 to 150 grains) of pegnin are required for 1 liter (34 fluidounces) of milk previously boiled and cooled to about 40° C. (104° F.). The mixture, after brief shaking, is allowed to stand 2 to 3 minutes, or until it is completely coagulated, and then shaken vigorously during several minutes until the coagulum has been converted into a smooth, homogeneous mixture, and set aside in a cool place. For infants it is transferred to the nursing bottle as required and heated in warm water to the body temperature (37.5° C., 99.5° F.) before feeding.

Manufactured by Farbwerke, vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York). U. S. patent No. 700,631 (May 20, 1902; expires 1919).

Peptic Preparations.

ELIXIR OF ENZYMES.—Elixir of enzymes is a solution containing pepsin and rennet in a menstruum containing 20 per cent. of alcohol.

Elixir of enzymes is a light yellow, palatable, liquid preparation. One part digests about 20 parts of coagulated egg albumin in 2½ hours. Eight Cc. (2 fluidrams) coagulate 500 Cc. (one pint) of milk in a few minutes.

Actions and Uses.—It is claimed to be useful as an aid to digestion and as a vehicle for various drugs.

Dosage.—1 to 8 Cc. (1 to 2 fluidrams) with meals; children in proportion.

Manufactured by Armour & Co., Chicago.

ENZYMOL.—Enzymol is a glycerin-aqueous acid extract prepared directly from *the mucous* membrane of the fresh animal stomach, free from alcohol, but containing a trace of thymol and having an acidity due to combined hydrochloric acid equivalent to 0.26 to 0.3 per cent. of actual hydrochloric acid. It contains no free hydrochloric acid, but does contain a slight excess of protein over that combined with the acid. It is adjusted to a definite proteolytic power and contains 25 per *cent. of* glycerin by weight.

Enzymol is a light straw-colored fluid.

The presence of proteins is shown by coagulation by heat or by the addition of alcohol. The proteolytic power when acidified and tested by the method of the U. S. P. for pepsin should be such that 4 Cc. will dissolve 800 Gm. of coagulated egg-albumin in two and one-half hours.

Action and Uses.—When applied to morbid tissues enzymol is said to have the power of dissolving *them by its* proteolytic action even without the addition of acid. It is said to dissolve necrotic bone, by virtue of the combined acid which it contains. Its physiologic action is said to cease in contact with living tissue.

Enzymol is said to be useful as an application to purulent and necrotic surfaces for the removal of the morbid materials.

Dosage.—It is made ready for use by the addition of one half to one or two volumes of water; for the solution of necrotic and carious bone it may be applied undiluted.

Manufactured by Fairchild Bros. & Foster, New York. U. S. trademark No. 44,769.

ESSENCE OF PEPSIN-Fairchild.—A solution of the milk-curdling and proteolytic ferments of the gastric glands in a menstruum containing 18.5 per cent. of alcohol by volume.

The solution is prepared by direct extraction *from the* peptic glands of the stomach.

One Cc. will curdle 250 Cc. of milk at 38° C. in a few minutes, and dissolve 50 Gm. of coagulated egg albumin when tested *according to the* directions of the United States Pharmacopeia.

Actions and Uses.—Essence of pepsin has the action of rennin and of pepsin and is recommended by the manufacturers for preparing milk and in cases in which pepsin is indicated.

Dosage.—4 Cc. (1 fluidram) or more.

Manufactured by Fairchild Bros. & Foster, New York.

DIGITALIS PREPARATIONS

The chemistry of digitalis is very imperfectly understood, but several principles have been isolated in a greater or less degree of purity. These include digitalin, digitalein, digitoxin, digitonin and digitin. The term digitalin, unfortunately, is applied in a loose way to all of these principles, and in a more restricted sense to indicate digitalinum verum, or true digitalin, which is probably a definite substance.

Digitalinum purum, or German digitalin, is a mixture of several glucosides, consisting of 50-60 per cent. of digitonin and only 5-6 per cent. of true digitalin. German digitalin is the preparation usually found on the market and is ordinarily dispensed when "digitalin" is prescribed.

French Digitalin, or Homolle's digitalin, is also a mixture of several glucosides, but consists *mainly* of true digitalin.

Merck's crystallized digitalin is neither digitalin nor digitoxin, but digitonin or digitin, Merck using the three terms, crystallized digitalin, digitonin and digitin as synonyms.

Digitaline crystallisée of Nativelle is not digitalin, but is nearly identical with digitoxin.

It must be remembered, therefore, that Merck's "crystallized" digitalin, Merck's "pure" digitalin and the "true" digitalin of Boehringer and Sons, which naturally might be supposed to be identical, are *different in their action.*

DIGALEN—Liquor Digitoxini Solubilis.—Digalen is a mixture said to contain 1 part of Digitoxinum soluble Cloetta,[1] in 1,000 parts of glycerin and 1,600 parts distilled water with 7.5 per cent. of alcohol. 1 Cc. is said to contain 0.0003 Gm. of Digitoxinum Solubile Cloetta.

Digitoxinum solubile Cloetta is manufactured as follows:

The dried and finely powdered leaves of digitalis are extracted with dilute alcohol; then the extract is mixed with lead acetate solution in order to remove chlorophyll and resins, and filtered. From this filtrate the excess of lead is precipitated with sodium sulphate and the alcohol distilled off in vacuo. From the remaining aqueous solution the substance is extracted by ethereal solvents and precipitated afterward in an amorphous and pure condition according to a special secret method.

Digalen is a colorless or slightly yellowish fluid of an agreeable aromatic smell and a sweet taste which turns bitter afterward.

Digitoxinum soluble *Cloett* [illegible] an amorphous, white or slightly yellow powde [illegible] id to be about five times as great as that of [illegible] It is said to dissolve very readily in alcoh [illegible] d a little less readily in ether. It has an intensely bitter taste and causes violent sneezing. It is claimed to be the form in which *digitoxin* exists in the digitalis leaf before it is deposited in a crystalline and insoluble form.

In order to test for the active principle in digalen, a *few drops* of dilute *acetic acid* are added to 2 Cc. of digalen *solution and* then the mixture is shaken out with chloroform. This *solution* is evaporated and the residue dissolved in about 2 Cc. *of glacial* acetic acid containing traces of iron chloride. If to this solution concentrated sulphuric acid is added cautiously without mixing, so as to form a separate layer at the bottom of the test tube, a small brown ring will form between the two layers, which becomes broader in the course of some hours and expands toward the top of the tube in a blue-green to black shade, and toward the bottom of it in a reddish-brown one, while the acetic acid acquires finally a dark green-blue color.

---

[1] The Council has *not* determined whether digalen contains "soluble amorphous digitoxin" or *not*, bue accepts it *merely* as a standardized soluble and fairly stable digitalis preparation.

Actions and Uses.—The same as Digitoxin.

(See Jour. A. M. A., May 8, 1909, p. 1499.)

Note.—Under certain conditions which have not yet been determined satisfactorily, digalen sometimes deteriorates, even when the bottle remains unopened.

Dosage.—Average single dose 1 Cc. (16 min.) Maximum single dose 2 Cc. (32 min.). Maximum daily dose 6 Cc. (96 min.). Intravenous injections of 1 Cc. (16 min.) may be repeated at intervals of one-half to one hour as necessary. For protracted dosage from 1 to 2 doses daily of from 7 to 14 drops are given.

Manufactured by F. Hoffmann-LaRoche & Co., Basel, Switzerland (The Hoffmann-LaRoche Chemical Works, New York). U. S. trademark No. 43,593.

DIGIPURATUM.—Digipuratum is a digitalis preparation said to contain digitoxin and digitalin in the form of tannates. It is standardized biologically by the method of Gottlieb. It is claimed that 85 per cent. of the inactive substances found in the ordinary extract have been removed and that it is free from digitonin.

Digipuratum is obtained by removing objectionable constituents from an alcoholic extract of digitalis, neutralized with alkaline hydroxides, by the addition of ether, petroleum benzene, or other suitable precipitant, and reducing the purified liquid to a powder, by evaporation with milk sugar.

Digipuratum is a greenish yellow, odorless powder of bitter taste. The active constituents of digipuratum are insoluble in cold water and diluted acids, but are easily soluble in weak alkalies.

Digipuratum responds to the following identity test: If 0.1 Gm. digipuratum is underlaid with about 3. Cc. of glacial acetic acid which contains 1 per cent. of a 5 per cent. solution of ferric sulphate, there appears a red band (presence of digitalin) and above this another, at first bright green, later changing to dark green and finally blue (presence of digitoxin).

To determine the digitoxin content, 10 Gm. of digipuratum are dissolved with moderate heat in 50 Cc. of water; 5 Cc. of 10 per cent. ammonia water are added and the liquid is then extracted with chloroform. The chloroformic extractions are filtered into a tared vessel and the chloroform removed by distillation. The residue is dissolved in 3 Gm. of chloroform and mixed with 7 Gm. of ether and 50 Gm. of petroleum ether. The separated flakes are collected on a small filter. Then the residue on the filter is dissolved in absolute alcohol, allowing the solution to run into the tared distilling vessel. The alcohol is then distilled off and the residue dried to constant weight. The digitoxin thus found should not amount to more than 0.04 Gm.

The physiologic activity is determined by the method of Gottlieb: 1 Gm. of digipuratum is treated with 19 Cc. of hot water and 1 Cc. of a 2 per cent. solution of sodium bicarbonate. If now 0.15 Cc., 0.2 Cc., and 0.25 Cc., respectively, of this solution is injected into the femoral lymphatics of freshly caught land frogs (Rana temporaria), weighing 30 Gm. each, the exposed heart of the animals should permanently be brought to a stop in the majority of instances (say in five out of six experiments) within half an hour after the administration of a 0.2 Cc. dose. If 0.2 Cc. of the 5 per cent. solution=0.01 Gm. of digipuratum, is sufficient to stop the systolic heart-beat within half an hour, then 1 Gm. of digipuratum will contain 100 units; should 0.25 Cc. of the 5 per cent. solution be necessary, the number of units of digipuratum it contains would be 80; if 0.25 Cc. should not yet prove sufficient, the preparation would be too weak to be effective; and should the systole be arrested after a dose of 0.15 Cc. within half an hour after injection, the preparation would be too strong.

The total physiologic activity having been determined, the relative amount that is due to digitoxin can be determined by using the digitoxin separated in the above quantitative determination and by the difference between this amount and the total physiologic activity the amount due to the digitalin alone can be estimated.

Actions and Uses.—The same as digitalis, but it is claimed that it is less liable to disturb the stomach and on account of its exact dosage cumulative effects can be more easily avoided than with other preparations of digitalis.

Dosage.—The same as digitalis.

Manufactured by Knoll & Co., Ludwigshafen a. Rh., Germany, and New York. U. S. patent No. 943,578 (Dec. 14, 1909; expires 1926). U. S. trademark No. 73,012.

Digipuratum Tablets, 1 1-2 grains.—Each tablet is said to contain digipuratum 0.1 Gm. (1 1/2 grains).

DIGITALEIN, CRUDE.—Digitaleinum Crudum.—Digitalein crude is a mixture of glucosides from digitalis purpurea prepared according to the process of Schmiedeberg, containing digitoxin, digitalin and digitalein.

Commercial digitalein is an amorphous, yellowish-white, bitter powder, soluble in water and absolute alcohol, insoluble in chloroform and ether. The aqueous solution foams on shaking. The solution yields a precipitate on addition of lead acetate, ammonia water or tannic acid.

Actions and Uses.—Digitalein acts on the heart like digitalis. It is a diuretic.

Its uses are the same as those of digitalis.

Dosage.—0.001 to 0.002 Gm. (1/60 to 1/30 grain) two or three times a day.

DIGITALIN, TRUE—Digitalinum verum Kiliani.—Schmiedeberg's digitalin. Digitalin, true, is a glucoside, $C_{35}H_{56}O_{14}$, found in the seeds and leaves of digitalis purpurea and derived commercially from German digitalin.

To a solution of one part German digitalin in four parts of 95 per cent. alcohol, five parts of ether by weight (Sp. Gr. 0.720) are added and the mixture allowed to stand in a closed vessel for twenty-four hours. In the clear supernatant solution the quantity of dissolved substance is estimated and the whole then subjected to a vacuum distillation until its weight becomes 1.6 times that of the total dissolved substance. To this concentrated solution water, in an omunt 2.4 times the weight of dissolved substance, is added, forming a solution containing approximately 20 per cent. alcohol, from which crude digitalin gradually separates on standing. The crude product is washed first with 10 per cent. alcohol and then with water, and finally dried at a [illegible] rther purification is effected by boiling [illegible] animal charcoal. (Kiliani's method. [illegible] Praxis, Vol. 1, p. 1030.)

Digitalin occurs as a white amorphous powder, or in characteristic, granular masses. It melts at 217° C. (412.6° F.) and becomes yellow. It is soluble in 1,000 parts of water and in 100 parts of 50 per cent. alcohol at the ordinary temperature; easily soluble in strong hot alcohol, but nearly insoluble in ether and [illegible] dissolved in alcohol and treated with very [illegible] yields digitaligenin and two sugars.

[illegible] sulphuric acid digitalin forms a golden yel[illegible] on the addition of potassium hypobromite [illegible] magnificent rose red or violet red.

[illegible] is dissolved in 3 to 4 Cc. of glacial acetic acid to which a trace of ferric chloride solution has been added and the mixture carefully underlaid with concentrated sulphuric acid (Keller's reaction) a deep carmine red band appears; the lower layer of the acetic acid is light yellow changing to brownish. (Difference from digitoxin.)

Sulphuric acid containing a little ferric sulphate gives with a little digitalin at first an intense golden yellow color, and then a red solution; this color rapidly changes to a beautiful and permanent violet. If too much digitalin is used the red color remains and only the surface layer becomes violet.

On heating on platinum foil digitalin should burn without leaving a weighable residue.

If a granule of digitalin is covered with 2 Cc. of 10 per cent. potassium hydroxide solution no color should develop within one minute (absence of other glucosides).

If digitalin is stirred to a thin paste with water and for every 100 parts of water used 22 parts of amyl alcohol is added with shaking, and the mixture set aside in a closed vessel for 24 hours, the presence of digitonin will be indicated by the formation of distinct masses of crystals.

Action and Uses.—The same as those of digitalis. Its cumulative action is probably not so great as that of digitoxin.

Dosage.—It is impossible at present to state the correct dose for digitalinum verum Kiliani. Some authorities give the same dose as that for digitoxin, whereas others give it as much larger. It is best given in pills made by trituration with sugar of milk and massing with glucose. Solutions of digitalin rapidly lose their strength and should be freshly prepared.

DIGITALIN, "FRENCH."—Homolle's Digitalin. Digitaline Amorphe. Digitaline Chloroformique. Digitalin, French, is a mixture obtained from Digitalis purpurea by the method of Homolle, consisting mainly of digitalinum verum, Kiliani.

100 Gm. powdered digitalis leaves are moistened with one liter of water and slowly exhausted in a percolator until the percolate amounts to three liters. This is precipitated with 250 parts of lead acetate and the filtrate from the precipitate treated with 40 parts of crystallized sodium carbonate and 20 parts of sodium ammonium phosphate, in order to remove the xcess of lead. The filtrate is precipitated with 40 parts of tannic acid. The tannate is mixed with 25 parts of powdered litharge and 50 parts of purified animal charcoal and dried. From the dried mass the digitalis bodies are extracted with 90 per cent. alcohol, the latter is distilled off and the residue washed with distilled water and again taken up in 90 per cent. alcohol. This is again distilled and the residue exhausted with chloroffrm. On expelling the latter the digitalin remains behind (Hager's Pharm. Praxis, Vol. I, p. 1935).

French digitalin is a yellowish-white, amorphous powder of a peculiar aromatic odor and little taste. It is neutral to litmus, almost insoluble in water, soluble in alcohol and chloroform and insoluble in ether. It softens at 90° C. and begins to melt at 100° C. It is not precipitated by solutions of lead salts, but with tannic acid it forms a tannate insoluble in water. It is colored emerald green by concentrated sulphuric acid.

Concentrated sulphuric acid dissolves digitalin French, producing a yellow color, which finally goes over to an emerald-green color.

Action and Uses.—Action like that of digitoxin. Uses the same as those of digitalis.

Dosage.—What has been said with regard to the dose of digitalinum verum, applies to the French digitalin: the dose is variously given as 0.00025-0.002 Gm. (1/250 to 1/35 grain). Maximum daily dose 0.006 Gm. (1/10 grain). It must be used with caution and its action carefully watched.

DIGITALIN, GERMAN—Digitanilum Germanicum.—Digitalin, German, is a mixture of glucosides obtained from digitalis seeds according to the process of Walz, and consisting largely of digitonin, with digitalin verum and other glucosides.

Digitalis seeds are extracted with alcohol, the alcohol driven off, the extract diluted with water and purified by precipitation with lead acetate. The filtrate is freed from lead by sodium phosphate. From the liquid thus purified the digitalis bodies are precipitated with tannic acid, the tannate well washed with water and decomposed with lead or zinc acetate. The digitalin thus separated is taken up in alcohol, the latter carefully distilled off and the residue washed with ether as long as it takes up anything. The digitalin purified in this way is dried at a low temperature and finally powdered. (Hager's Handbuch der Pharm. Praxis, 1903, Vol. I, p. 1032.)

German digitalin is a yellowish-white, amorphous powder, soluble in water and alcohol, insoluble in ether and chloroform. It is said to contain about 50-60 per cent. of digitonin and 5-6 *per cent. of digitalinum* verum, the remainder being digitalein and other glucosides.

Sulphuric acid containing a trace of ferric sulphate produces with digitalin, German, an intense golden-yellow coloration, changing to red and finally to a permanent reddish-violet.

Action and Uses.—Similar to those of digitalis.

Dosage.—0.001 to 0.002 Gm. (1/60 to 1/30 grain). Maximum dose 0.004 Gm. (1/16 grain): maximum per day, 0.02 Gm. (⅓ grain). Doses of from 1/10 to ⅓ grain, and even higher, have been used by some clinicians.

As German digitalin (so-called digitalinum purum) is a mixture of very powerful active principles, the proportion of which may vary with changes in the manipulations, it is very important that the directions for its preparation should be very carefully followed, and caution should be exercised to purchase only such products as the manufacturers can guarantee to have been made with the necessary care.

DIGITONIN.[1]—Digitonin is a glucoside $C_{27}H_{48}O_{14} + 5H_2O$ *derived from the seeds of digitalis purpurea and belonging to* the saponins.

Digitonin is separated from German digitalinum purum by the addition of ether to the alcoholic solution (see digitalin). The *precipitate is dissolved in 10 parts of 85 per cent. alcohol* and the solution put into water at 45° C. After standing from six to eight hours the greater part of the digitonin will crystallize out.

Digitonin crystallizes in colorless needles or thick warty masses which dissolve in 600 parts of cold water and 50 parts of warm water to a turbid solution, but dissolves to a clear solution in 50 parts of 50 per cent. alcohol. Its solutions are levorotatory. When heated in alcoholic solution with hydrochloric acid it is split into dextrose, galactose and digitogenin.

Concentrated sulphuric acid dissolves it with a red color which is intensified by the addition of a drop of bromine water.

Concentrated hydrochloric acid dissolves digitonin without color, but the solutions become yellow and finally reddish violet on heating or on long standing.

Keller's reaction gives a rose red zone which soon fades.

Action and Uses.—Digitonin acts as a heart depressant when introduced into the circulation, but it is not absorbed from the alimentary canal, and therefore exerts no action on the circulation when taken by the mouth, but it renders digitoxin more soluble whether in infusion or when the leaf is taken by the mouth.

DIGITOXIN—Digitoxinum.—Digitoxinum (Pharm. Helvetica, edit. 4). Digitaline Crystallinée (Pharm. Française, 1908). Digitoxin, $C_{34}H_{54}O_{11}$ is the chief active principle of digitalis, having the character of a glucoside.

The leaves of Digitalis purpurea having been extracted with water and dried, are extracted with 50 per. cent. alcohol. This solution is treated with lead acetate, forming a precipitate, which is allowed to settle. The supernatant liquid is decanted. The remaining alcohol is evaporated *in vacuo* and the residue repeatedly extracted with ether. The ether extract is then shaken out with water and concentrated by distillation and the residue recrystallized from hot alcohol (85 per cent.) and decolorized by boiling with animal-charcoal (Schmidt's Pharm. Chemie, 3d edit., Vol. II, p. 1640).

Depending on the solvent from which it is crystallized, it is either hydrated on anhydrous. The hydrated form is obtained when crystallized from alcohol and the anhydrous from chloro*form and* alcohol mixture, forming colorless rectangular leaflets melting at 243° C. (470° F.) (Pharm. Française, 1908). The anhydrous preparation is official in the Pharm. Française, 1908.

It is insoluble in water, benzin or carbon disulphide, slightly soluble in ether and easily soluble in chloroform. At 15° C. it is soluble in 79.80 parts of absolute alcohol and in 43.04 parts of 90 per cent. alcohol. It is slightly soluble in fatty oils (Pharm. Française, 1908).

Digotoxin dissolved in 2 Cc. glacial acetic acid containing a trace of ferric chloride when poured onto 2 Cc. of concentrated sulphuric acid containing a trace of ferric chloride, will produce a brown color at the zone of contact of the two solutions. This color gradually changes to green and finally an indigo blue; after one-half hour the entire acetic acid layer will become blue. (Pharm. Française, 1908).

It dissolves to a colorless solution in cold concentrated hydrochloric acid, but when this solution is heated on the water bath for some time a green color is obtained. Concentrated sulphuric acid dissolves it, producing a green color.

It should not lose weight appreciably when heated to 100° C. It should be insoluble in water and in benzin, but completely soluble in chloroform. It should leave no residue when ignited (Pharm. Française, 1908).

Action and Uses.—Digitoxin acts much like digitalis. Its activity varies with the method of preparation. Digitoxin from an unknown source should be tested on animals before it is used on patients. Owing to its slow excretion, it is cumulative in action when too frequently repeated. Locally it is very irritant, and when given by mouth is liable to derange the digestion. Penzoldt claims that gastric irritation may be avoided by giving it only when the stomach is full. Owing to its irritant action it is not suitable for hypodermic injection.

Dosage.—Single dose 0.00025 (1/250 grain); maximum daily dose 0.0010 Gm. (1/67 grain). It should be given largely diluted and repeated cautiously.

Antidotes: Emetics, tannin, nitroglycerin, morphine, alcoholic stimulants or camphor.

DOLOMOL.—Dolomol is magnesium stearate, $Mg(C_{18}H_{35}O_2)_2$, containing small amounts of magnesium palmitate and oleate.

It is a white powder, insoluble in water, unctuous to the touch, nearly odorless and tasteless. It is claimed to be practically free from oleate. Its magnesium content corresponds to nearly 7 per cent. MgO.

Actions, Uses and Dosage.—Acting as a protective to the skin, Dolomol is employed in cutaneous affections as a dusting powder, alone or mixed with various remedies.

The following dolomol compounds are listed: Dolomol-Acetanilid, 25 per cent.; Dolomol-Acid Boric, 20 per cent.; Dolomol-Acid Carbolic, 5 per cent.; Dolomol-Acid Picric, 25 per cent.; Dolomol-Acid Pyrogallic, 5 per cent.; Dolomol-Acid Salicylic, 5 per cent.; Dolomol-Acid Salicylic, 10 per cent.; Dolomol-Acid Tannic, 10 per cent.; Dolomol-Alum, 10 per cent.; Dolomol-Aristol, 10 per cent.; Dolomol-Balsam Peru, 10 per cent.; Dolomol-Bismuth Subgallate, 25 per cent.; Dolomol-Calendula, 25 per cent.; Dolomol-Calomel, 25 per cent.; *Dolomol-Camphor*, 10 per cent.; Dolomol-Chrysarobin, 5 per cent; *Dolomol-Europhen*, 10 per cent.; Dolomol-Guaiacol, 5 per cent.; Dolomol-Ichthyol, 10 per cent.; Dolomol-Iodoform Deodorant, 10 per cent.; Dolomol-Menthol, 5 per cent.; Dolomol-Naphthol, 5 per cent.; Dolomol-Oil of Cade, 10 per cent.; Dolomol-Resorcin, 10 per cent.; Dolomol-Salol, 10 per cent.; Dolomol-Sulphur Sub., 25 per cent.; Dolomol-Tar, 10 per cent; Dolomol-Thymol, 2 per cent.

Manufactured by Pulvola Chemical Co., New York. Not patented or trademarked.

EMETINE HYDROCHLORIDE—Emetinæ Hydrochloridum.—Methyl-cephaeline. Emetine hydrochloride is the hydrochloride, $C_{15}H_{22}N.O_2.HCl.3H_2O$, of a base found together with cephaeline in Cephaelis Ipecacuanha.

Emetine hydrochloride occurs as a white crystalline powder, soluble in water and alcohol. A freshly prepared concentrated solution of ammonium molybdate in concentrated sulphuric acid is colored brown by emetine; this color changes to violet when a drop of concentrated hydrochloric acid is added. The general alkaloidal reagents precipitate emetine, even from dilute solutions. Alkalies precipitate emetine from aqueous solutions of its salts.

Actions and Uses.—Emetine acts similarly to Ipecac but is relatively more nauseant and less emetic, and causes relatively less renal irritation, but more cardiac depression.

Dosage.—Expectorant, 0.005-0.01 Gm. (1/12-1/6 grain). 0.01-0.02 Gm. (1/6-1/3 grain) causes emesis, but cephaeline is preferred as an emetic.

EMPYROFORM.—Empyroform is a condensation of birch tar and formaldehyde.

According to the patent specifications birch tar is boiled with formaldehyde solution and the hot liquid poured into hydrochloric acid. When cold, the solid mass is collected and washed until *free from acid.*

It is a grayish-brown, almost odorless powder, insoluble in water, but soluble in acetone and chloroform.

Actions and Uses.—Empyroform is an antipruritic, sedative *and desiccant.* It is said to be superior to tar and free from irritant or toxic effects. See note under Creosote Carbonate.

---

[1] Crystallized digitalin—Merck.

It is claimed to be useful in all stages of eczema, psoriasis, lichen, urticaria, prurigo, pityriasis, etc.

Dosage.—It is applied as a 5 to 10 per cent. ointment, 10 to 20 per cent. zinc paste, 10 to 20 per cent. tincture, and 37.5 per cent. suspension.

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin, Germany (Schering & Glatz, New York). U. S. patent No. 761,260 (May 31, 1904; expires 1921). U. S. trademark No. 43,419.

EPICARIN.—Oxynaphthyl-Ortho-Oxytoluic Acid.—Epicarin, $C_6H_3(OH)(COOH)(CH_2C_{10}H_6OH)2:3:1 = C_{18}H_{14}O_4$, is β-naphthol-hydroxy-toluic acid.

It is obtained by the action of chlormethyl-salicylic acid on a solution of *b*-naphthol, in glacial acetic acid, thus:

$$C_6H_3(OH)\ (COOH)\ (CH_2Cl + C_{10}H_7OH = C_6H_3(OH)\ (COOH)\ (CH_2C_{10}H_6OH) + HCl$$

It forms colorless or yellowish needles, melting at 190° to 195° C. (380° to 389° F.) difficultly soluble in water, but easily soluble in alcohol, ether, acetone, and in soaps. It dissolves in oils on the addition of a little ether. It has the character of a strong acid, forming well crystallized salts, which, however, are sparingly soluble in water, particularly the sodium salt. On exposure to air it acquires a reddish color due to oxidation; if it is then recrystallized from glacial acetic acid, colorless crystals are again obtained which melt at 166° C. (338° F.). These, however, retain a little acetic acid, but lose this by heating at 120° C. (248° F.).

The alcoholic solution of epicarin produces an intense blue color with ferric chloride. When heated with concentrated sulphuric acid, a red-brown solution, having a vivid green fluorescence, is produced. If shaken with chloroform and solution of potassium hydroxide, a yellowish color, changing later to yellowish green, is developed, thus distinguishing epicarin from *b*-naphthol, which produces a deep blue color under the same conditions.

Being a strong acid, it is incompatible with alkaline hydroxides or carbonate, especially those of sodium, with which it forms an almost insoluble salt. It should not be exposed to the air, which colors it red.

Actions and Uses.—Epicarin is a non-poisonous antiseptic and parasiticide. Administered internally, it is excreted mostly undecomposed. It is said to be useful in the treatment of skin diseases, particularly scabies, tinea tonsurans, prurigo and certain forms of eczema. (See note under Creosote Carbonate.)

Dosage.—It is used only externally in the form of a 5 to 20 per cent. ointment, with petrolatum or wool fat (lanolin) as base, or in the form of oily or alcoholic solutions (10 per cent).

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 671,622 (April 9, 1901; expires 1918).

EPINEPHRINE PREPARATIONS

EPINEPHRINE.—Epinephrine is 1, 2-dihydroxy-4^2-methyl-amino ethyl-4^1-ol benzene, $C_6H_3(OH)_2(CHOH.CH_2NHCH_3)$, a substance with feeble basic properties, obtained from the suprarenal gland of the sheep or other animal.

Epinephrine is a finely crystalline white or yellowish powder, odorless and slightly bitter. It melts at 201 to 207° C. (401 to 404° F.), turning brown and decomposing at the higher temperature.

The alkaloid shows a slightly alkaline reaction to moistened red litmus paper. It is almost insoluble in cold water, more readily in hot water. It is difficultly soluble in alcohol and insoluble in ether. The colorless aqueous solution of the alkaloid is easily oxidized on contact with the air, becoming pink, then red, and eventually brown. The base reacts with acids to form salts which are readily soluble in water; it is also soluble in the fixed alkalies, but not in ammonium hydroxide or in solutions of the alkaline carbonates. The following reactions are the most characteristic: The addition of ferric chloride to a solution of the alkaloid produces a beautiful emerald green color which by careful addition of caustic alkali becomes purple, and then carmine red. Strong acid prevents the reaction with ferric chloride, limiting the change of color to a dirty yellowish-green. It gives a vivid pink color with iodine. The alkaloid reduces silver salts and gold chloride very energetically, and the liquid turns red. A drop of 1:10,000 solution instilled into the eye will, within a few seconds, produce a pallor of the conjunctiva.

Its incompatibilities are the same as those of other alkaloids. Its solutions should be kept tightly stoppered and protected from the light.

Actions and Uses.—Epinephrine acts peripherally on a variety of structures, probably by stimulating the sympathetic nerve endings. Its most important therapeutic actions consist in a constriction of the blood vessels, with consequent high rise of blood pressure; a stimulation of the vagus center with slowing of the heart, and a direct stimulant and tonic effect on the heart muscle, similar to digitalis. Large doses also cause glycosuria. Continued administration of large doses leads to atheroma. The effect of a single dose is very fleeting. It is not irritant. The effects are seen on local application and intravenous and intramuscular injection. When given to animals, by mouth or hypodermically, moderate doses have almost no action.

Dilute watery solutions rapidly lose their strength, the deterioration being accompanied by a reddish or brownish discoloration.

The alkaloid is used mainly locally for its vasoconstrictor action, in hemorrhage, and in catarrhal and congestive conditions. It is said to cut short the asthmatic paroxysm (being used by spraying the larynx and by hypodermic injections). Intravenous injections are effective in shock and anesthesia accidents (care being taken not to give an overdose). It has also been recommended in heart disease, Addison's disease, etc., but opinions are divided as to the benefits to be expected from oral administration.

The vasoconstrictor action of epinephrine is used to intensify and prolong the anesthetic effect of local anesthetics by retarding the circulation in the affected part and thus hindering the dilution of the anesthetic agent by too rapid absorption into the general blood stream.

Dosage.—0.3 to 2.0 Cc. (5 to 30 minims) of a 1:1,000 solution every two or three hours. Hypodermically, 0.06 to 1 Cc. (1 to 15 minims) of a 1:1,000 solution, diluted with sterile water. Locally it is used in solution varying in strength from 1:15,000 to 1:1,000, for ordinary applications, in oily solution for sprays, in ointment for application to mucous membranes, such as the eye or the nose, where a slower but more lasting action is desired and in suppositories. Since the alkaloid is insoluble, solutions in water should be made of some salt, but for the oily solutions the alkaloid itself should be employed.

Proprietary Preparations:

ADNEPHRIN.—The name used for epinephrine by F. Stearns & Co., Detroit, Mich.

Adnephrin Emollient.—An ointment composed of adnephrin and a neutral base (1:1,000).

Adnephrin Oil Spray.—A 1:1,000 solution of adnephrin in a neutral oil, aromatized.

Adnephrin Solution.—A sterile solution (1:1,000 of adnephrin in physiologic salt solution containing one-half of 1 per cent. of methaform (chlorbutanol). A small proportion of sodium sulphite is added to the extraction of the glands.

Adnephrin Suppositories.—Each suppository represents a 1 to 1,000 with oil of theobroma and weighs about

ADRENALIN.—The name used for epinephrine by Parke, Davis & Co., Detroit, Mich. It is prepared by the method of Takamine.

For Tests, Incompatibilities, Actions and Uses see Epinephrine. U. S. patents Nos. 730,175, 730,176, 730,196, 730,197, 730,198 (June 2, 1903; expires 1920); 753,177 (Feb. 23, 1904; expires 1921). U. S. trademark.

Adrenalin Chloride Solution.—A 1:1,000 solution of adrenalin hydrochloride in physiologic salt solution, preserved by the addition of 0.5 per cent. of chloretone (chlorbutanol).

Adrenalin Inhalant.—A neutral oily solution containing adrenalin chloride 1:1,000, 3 per cent. of chloretone, 13 per cent. of alcohol, and aromatics.

Adrenalin Ointment.—One part of adrenalin chloride in 1,000 parts of oleaginous ointment base.

Adrenalin and Chloretone Ointment.—Contains 0.1 per cent. of adrenalin chloride, and 5 per cent. of chloretone in an ointment base of hydrous wool fat and petrolatum.

Adrenalin Suppositories.—1 part of adrenalin to 1,000 parts of oil of theobroma (cacao butter). Each suppository weighs about 1 Gm. (15 grains).

Adrenalin Tablets.—Each tablet contains 0.001 Gm. (3/200 grain) adrenalin, as borate, yielding a 1:1,000 solution when dissolved in 15 minims (1 Cc.) of water.

Adrenalin and Cocaine Tablets.—Each hypodermic tablet contains cocaine hydrochloride 0.01 Gm. (1/6 grain), and adrenalin, as borate, 0.0002 Gm. (1/300 grain).

ADRIN.—The name (word mark) used for epinephrine by H. K. Mulford Co., Philadelphia. It is prepared by the method of von Fuerth (Zeit. f. physiol. chem., vol. 26, p. 18). It is not marketed in its pure form. All the preparations contain boric acid.

U. S. trademark No. 41,916.

Adrin Compound Vaginoids.—Vaginal Suppositories of Epinephrine Compound, Mulford. Each suppository contains adrin 0.00065 Gm. (1/100 grain), ichthyol 0.13 Cc. (2 minims), phenol 0.13 Gm. (2 grains), zinc phenolsulphonate 0.08 Gm. (1¼ grains) in a boroglyceride and gelatin base and weighs about 7.63 Gm. (118 grains).

Adrin Inhalant Comp.—Epinephrine Inhalant Comp., Mulford. —Each 100 Cc. contains epinephrine (as hydrochloride), 0.1 Gm. (7/16 of a grain in a fluidounce), camphor, 0.3 Gm. (1 1/3 grains in a fluidounce), menthol 0.22 Gm. (1 grain in a fluidounce), thymol, 0.043 Gm. (1/5 of a grain in a fluidounce), oil of eucalyptus, 0.22 Gm. (1 minim in a fluidounce), and hydrastine, 0.0053 Gm. (1/40 of a grain in a fluidounce), oil of wintergreen, 0.99 (4.5 minims in a fluidounce). The solvent is a mixture of castor and cotton seed oils, together with 10 per cent. absolute alcohol by volume.

Adrin Troches.—Troches of E[illegible] troche contains epinephrine, 0.000033 [illegible] 0.0013 Gm. (1/50 grain), benzoic acid, [illegible], oil of gaultheria, 0.0034 Gm. (1/20 grain), and eucalyptol, 0.0013 Gm. (1/50 grain). The base is sugar with a small amount powdered acacia.

Adrin Ointment.—Ointment of Epinephrine, Mulford. An ointment containing 0.1 per cent. each of adrin and boric acid in a base of petrolatum and anhydrous wool fat, flavored with oils of wintergreen and eucalyptus.

Adrin Solution 1:500.—Solution of Epinephrine, 1:500, Mulford. A solution of adrin, 1 to 500, in normal salt solution, containing boric acid, 0.25 per cent., and also small quantities of sulphite and chloroform.

Adrin Suppositories.—Suppositories of Epinephrine, Mulford. Each suppository contains adrin 0.0027 Gm. 1/25 grain) and oil of theobroma, 1.23 Gm. (19 grains).

Adrin Tablets, 1/65 grain.—Tablets of epinephrine, 1/65 grain, Mulford. Each tablet contains adrin, 0.001 Gm. (1/65 grain); sodium chloride, 0.007 Gm. (1/10 grain); boric acid, 0.002 Gm. (1/33 grain). A 1:1,000 solution is prepared by dissolving a tablet in 1 Cc. (16 minims) of water. The tablets can be used hypodermically.

Adrin Tablets, Hypodermic, 1/100 grain.—Tablets of Epinephrine, hypodermic, 1/100 grain, Mulford. Each tablet contains adrin 0.00065 Gm. (1/100 grain) and represents 0.6 Cc. (10 minims) of the 1:1,000 solution.

Adrin Tablets, Hypodermic, 1/200 grain.—Tablets of Epinephrine, 1/200 grain, Mulford. Each tablet contains adrin 0.00033 Gm. (1/200 grain) and represents 0.3 Cc. (5 minims) of the 1:1000 solution.

Adrin and Cocaine Tablets. Tablets of Epinephrine and Cocaine, Mulford. (For dental practice). Each tablet contains adrin, 0.00065 Gm. (1/100 grain) and cocaine hydrochloride, 0.016 Gm. (¼ grain).

Adrin and Sparteine Tablets, Hypodermic.—Tablets of Epinephrine and Sparteine, Hypodermic, Mulford. Each tablet contains adrin 0.00033 Gm. (1/200 grain) and sparteine sulphate, 0.008 Gm. (⅛ grain).

SUPRACAPSULIN.—The name used for epinephrine by The Cudahy Packing Co., South Omaha, Neb.

Not patented. U. S. trademark No. 72,580.

Supracapsulin Solution.—A solution 1:1,000 of supracapsulin in normal salt solution with small quantity of sulphite and 0.5 per cent. of chloral.

Supracapsulin Inhalant.—A solution 1:1,000 of supracapsulin in an aromatized neutral oil, containing approximately 2.5 per cent. of chloral and 10 per cent. of alcohol.

SUPRARENALIN.—The name used for epinephrine by Armour & Co., Chicago.

An organic base is used for the the final precipitation.

U. S. patent No. 829,220 (Aug. 21, 1906; expires 1923).

Suprarenalin Inhalant.—A 1:1,000 solution of suprarenalin in an aromatized oil, containing approximately 10 per cent. of alcohol.

Suprarenalin Ointment.—An ointment containing 0.1 per cent. of suprarenalin, dissolved in a petrolatum base.

Suprarenalin Solution.—A 1:1,000 solution of suprarenalin sulphite in normal saline solution, free from other preservatives.

Suprarenalin Triturates.—Triturates composed of suprarenalin, milk sugar, and boric acid, in such proportion that each 0.03 Gm. (½ grain) triturate dissolved in 15 minims of water, yields a 1:1,000 solution.

L-SUPRARENIN SYNTHETIC.—L-suprarenin synthetic is epinephrine produced synthetically according to the method of Stolz & Flaecher (*Ztschr. f. physiol. Chem.*, 58, p. 189).

L-suprarenin synthetic is a white odorless powder nearly insoluble in water, alcohol and ether. It melts at 211°-212°. It has the power of rotating polarized light to the left:—

$$[a]\frac{19.6^\circ}{D} = -51.4^\circ$$

L-suprarenin synthetic has the chemical and physical properties and physiologic effect of natural epinephrine obtained from suprarenal glands.

Manufactured by Farbwerke vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany. (Victor Koechl & Co., New York.) German patent No. 222,451.

L-SUPRARENIN SYNTHETIC BITARTRATE.—L-suprarenin synthetic bitartrate is the acid tartrate of l-suprarenin synthetic.

It is a white odorless powder readily soluble in water yielding an acid solution. It melts at 149° and rotates polarized light to the left.

Manufactured by Farbwerke vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany. (Victor Koechl & Co., New York). German patent No. 222,45

SUPRARENAL LIQUID—Liquor Suprarenalis (P. D. & Co.). —Suprarenal liquid is an aqueous extract of suprarenal glands, preserved with 0.8 per cent. of chlorbutanol (chloretone). Each Cc. (16 minims) of the solution represents 1 Gm. (15.4 grains) of the fresh glands.

Dosage.—The preparation is used undiluted for spraying, especially for mucous membranes.

Prepared by Parke, Davis & Co., Detroit, Mich.

ERGOTININE CITRATE—Ergotininæ Citras.—The citrate of ergotinine, a crystalline alkaloid, probably $C_{35}H_{39}O_5N_5$, (Barger and Carr) derived from ergot.

Ergotinine is obtained by extracting the residue left on evaporation of an alcoholic tincture of ergot with light petroleum to remove oily matter, dissolving the residue in ethyl acetate and shaking with citric acid solution. Sodium bromide or hydrobromic acid is then added and the precipitated hydrobromides of the alkaloids, ergotinine and ergotoxin are collected. The mixed hydrobromides are dissolved in caustic soda and shaken with ether; in this way ergotinine is removed first. Finally, the ergotinine is crystallized from alcohol, leaving ergotoxine and impurities in the mother liquor. By interaction of ergotinine with citric acid, ergotinine citrate is obtained.

Ergotinine citrate is a grayish-white, amorphous powder, slowly soluble in water; it has an acid reaction to litmus paper.

Ergotinine crystallizes in long needles, the sides of which are not quite parallel, which darken and melt at temperatures from 219° to 229° C. One part of ergotinine dissolves at 18° in 292 parts of alcohol, 1,020 parts of absolute ether, in 91 parts of ethyl acetate, and is moderately soluble in acetone and benzene, and readily soluble in chloroform. It is insoluble in light petroleum and in water. Its specific rotation in alcoholic solution saturated in the cold is + 338°. It forms salts which produce colloidal solutions in water which are precipitated by electrolytes so that they are little soluble in the presence of the stronger mineral acids.

Tests: Ergotinine citrate when carefully decomposed by alkali, the mixture extracted with ether and the ether evaporated yields a residue which responds to the test for ergotinine. Solutions of ergotine have a bluish violet fluorescence, especially when acidified. Concentrated sulphuric acid colors the alkaloid at first yellow, after some hours violet and at length blue. If a small quantity of ergotinine is dissolved in concentrated sulphuric acid and a trace of ferric chloride added, the mixture takes on an orange red coloration, which soon passes into red while the edges of the liquid are colored blue or bluish green.

If a few milligrams of ergotinine are dissolved in about 4 Cc. of glacial acetic acid a trace of ferric chloride added and the mixture underlaid with concentrated sulphuric acid a beautiful violet color appears at the junction of the two liquids.

Actions and Uses.—According to the investigations of Barger and Dale, ergotinine has very slight physiologic activity when it enters the system unchanged, but it is liable to be converted to a certain extent into ergotoxine, which possesses marked physiologic activity and appears to represent the pharmacologic actions of ergot. The action of ergotinine when given per os or when injected hypodermically, is variable in intensity but represents the action of ergot.

Ergotinine citrate can be used as a substitute for ergot, and is said to act efficiently, when injected hypodermically, in the treatment of headaches and of uterine hemorrhage. Combined with strychnine it is said to be useful as a stimulant in uterine hemorrhage.

Dosage.—.00032 to .00064 Gm. (1/200 to 1/100 grain), hypodermically.

Proprietary Preparations:

TABLOID ERGOTININE CITRATE—Tabloid Ergotininæ Citratis.—Each tablet contains ergotinine citrate 0.00032 Gm. (1/200 grain).

Dosage.—One or two, hypodermically.

Prepared by Burroughs, Wellcome & Co., London, England, and New York. U. S. trademark on "Tabloid" Nos. 11,993, 43,563, 43,559, 43,569, 44,219.

TABLOID ERGOTININE CITRATE AND STRYCHNINE SULPHATE.—Tabloid Ergotininæ Citratis et Strychninæ Sulphatis.—Each tablet contains ergotinine citrate 0.00065 Gm. (1/100 grain) and strychnine sulphate 0.0032 Gm. (1/20 grain).

Dosage.—One or two, hypodermically.

Prepared by Burroughs, Wellcome & Co., London, England, and New York. U. S. trademark, as for Tabloid Ergotinine Citrate.

EXTRACT OF ERGOT, PURIFIED — Extractum Ergotæ Purificatum.—Ergotin Bonjean. Extractum secalis cornuti (Pharm. Helvetica, edit. 4); Extractum ergoti (Pharm. Française, 1908). Purified extract of ergot is an aqueous extract of ergot purified by alcohol.

Powdered ergot is extracted by percolation with water and the percolate concentrated, diluted with alcohol, allowed to stand, then filtered and the filtrate evaporated to a soft extract.

It is reddish brown, of characteristic odor and taste, soluble in water and in a mixture of equal parts of water and alcohol. The aqueous solution is yellowish brown and acid in reaction (Pharm. Helvetica, edit. 4).

If 2 Cc. of an aqueous solution (1:20) is mixed with 7 Cc. of water and 1 Cc. Mayer's reagent there should appear at most but slight turbidity; the turbidity is increased by the addition of a trace of hydrochloric acid; the further addition of 5 drops of dilute acid produces within a few minutes a flocculent precipitate.

10 Cc. of a 1:20 *solution of purified* extract of ergot should become turbid upon the addition of 1 Cc. picric acid solution and precipitation should occur within five minutes.

If a solution of 0.2 Gm. purified extract of ergot in 5 Cc. water is made alkaline with 1 to 2 drops of ammonia water and then shaken out with ether, the ether extract evaporated and the residue dissolved in 2 Cc. acetic acid to which a trace of ferric chloride has been added and the mixture carefully poured upon concentrated sulphuric acid, a bluish violet color appears at the zone of contact (Pharm. Helvetica, edit. 4).

Action and Uses.—Purified extract of ergot has the action and uses of ergot.

Dosage.—0.2 to 0.5 Gm. (3 to 8 grains).

This preparation should not be confused with the following:

Ergotin Wernich (Pure Dried) is a purified and dialyzed dried aqueous extract of ergot.

Ergotin Wernich (Liquid) is a dialyzed extract of ergot, in the form of a reddish brown liquid.

Ergotin Wernich (Soft) is a purified and dialyzed soft extract of ergot; a reddish brown syrupy liquid.

Ergotin Wiggers (Pure Dried) is a dried, alcohol purified extract of ergot.

Ergotin Yvon is a fluidextract of ergot prepared by extracting with dilute solution of tartaric acid.

ERYTHROL TETRANITRATE.—Tetranitrol.—Erythrol tetranitrate, $C_4H_6(NO_3)_4 = C_4H_6O_{12}N_4$, is the tetranitrate of erythrite (butane-tetrol) $C_4H_6(OH)_4$.

It is obtained by the nitration of the tetratomic alcohol erythrite.

It forms colorless crystalline scales, insoluble in cold water, readily soluble in alcohol, melting at 61° C. (141.8° F.). On percussion it expodes much like nitroglycerin.

Actions and Uses.—It is a vasodilator and antispasmodic, like nitroglycerin. Its action is slower and more lasting; it begins in 15 minutes and persists for three or four hours.

It is said to be useful in angina pectoris and vascular diseases. It is reported as especially useful as a prophylactic in preventing anginal pain.

Dosage.—0.03 to 0.06 Gm. (½ to 1 grain) every four to six hours. Because of its explosiveness it is best dispensed in tablets.

Proprietary Preparations:

ERYTHROL TETRANITRATE TABLETS, Merck. Each tablet contains erythrol tetranitrate 0.03 Gm. (½ grain).

Prepared by E. Merck, Darmstart, Germany (Merck & Co., New York). German patent No. 81.664.

ETHYL AMINOBENZOATE.—Aethylis Amino-Benzoas.—Paramidobenzoic Acid Ethyl Ester.—Ethyl aminobenzoate, $C_6H_4NH_2COO(C_2H_5)$ 1:4, is the ethyl ester of paraminobenzoic acid, $C_6H_4NH_2COOH$, 1:4.

Paranitrobenzoic acid is obtained by the oxidation of paranitrotoluene, and this *may be ethylized* by the action of sulphuric acid and alcohol and the ester so obtained reduced *to* paramidobenzoic acid ethyl ester by the action of zinc and *hydrochloric* acid, or the acid may first be reduced and subsequently converted into the ethyl ester.

It is a white, crystalline powder, easily reduced to impalpability, melting at 90° to 91° C. *(194° to* 195.8° F.); odorless and tasteless, but producing a sensation of numbness when placed on the tongue; *almost insoluble* in cold and difficultly soluble in hot water; soluble in *six parts of alcohol*, in ether, benzene and to the amount of 2 to 3 per cent. in fatty oils. In oil solutions it may be *sterilized* without decomposition, but by prolonged boiling or by warming with dilute alkalies it is split up into alcohol and paramidobenzoic acid.

It should form clear, colorless and neutral solutions in alcohol or ether; after acidification with *nitric acid* it should not give a precipitate with silver nitrate. Its solution in dilute hydrochloric acid (1 to 10) is not *affected* by *hydrogen* sulphide. If a few drops of sodium nitrate solution be added to the slightly acidulated aqueous solution followed by some alkaline betanaphthol solution, a cherry red *coloration* of bluish shade is produced, which changes to orange on *further addition* of hydrochloric acid. It is decomposed by prolonged heating with water and is incompatible with alkalies and their carbonates.

Action and Uses.—It was introduced as a substitute for cocaine and is a local *anesthetic, similar* in its action to orthoform and said to be equally *effective*, but free from irritant action and toxicity. The anesthetic action, like that of the related compound orthoform, resembles that of cocaine, but is purely local, does not penetrate the mucous membranes, and in consequence of its insolubility the compound cannot be used by hypodermic injection. In consequence of its insolubility the anesthetic effect is more prolonged than that of cocaine.

It is said to be useful in various forms of gastralgia, in ulcer and cancer of the stomach for the relief of pain, and is applied locally in rhinologic and laryngeal affections, urethritis, etc.; it is also employed for anesthetizing wounded surfaces, burns, ulcerations and painful affections of the skin. It is more effective in cases where the skin is broken.

Dosage.—Internally, 0.3 to 0.5 Gm. (5 to 8 grains), in pastilles. Externally it is applied as a dusting powder, either pure or diluted. It may be applied in ointment or in the form of suppositories.

Manufactured by Farbwerke, vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York). German patents Nos. K 19,416 Onm.

ETHYL BROMIDE—Aethylis Bromidum.—Aether Bromatus (Pharm. Germanica, edit. 4; Pharm. Belgica, edit. 4; Pharm. Helvetica, edit. 4). Aethylium bromatum (Pharm. Française, 1908).

Ethyl bromide, C_2H_5Br, is the hydrobromic acid ester of ethyl alcohol, containing approximately 1 per cent. ethyl alcohol.

Ethyl bromide is a colorless, strongly refractive, easily volatile liquid, having a pleasant ethereal odor. It is insoluble in water, but readily soluble in alcohol and in ether. It boils at from 38° *to* 40° C. (101° to 104° F.). Its specific gravity at 15° is 1.453 to 1.457 (Pharm. Germanica).

It is stable when pure, but when contaminated with ethyl iodide it becomes colored when exposed to light. It burns with difficulty. It is very difficultly saponified by potassium hydroxide and it is not attacked by sulphuric or nitric acids. Silver nitrate gradually precipitates silver bromide (Pharm. Française, 1908). If a mixture of 1 Cc. ethyl bromide, 5 Cc. alcohol and 10 drops of (15 per cent.) sodium hydroxide solution is heated to boiling, cooled, acidified with dilute sulphuric acid, then shaken with chloroform and chlorine water added a brown coloration will be produced in the chloroform layer. If equal volumes of ethyl bromide and sulphuric acid are shaken together in a bottle previously rinsed with sulphuric acid and closed with a *glass* stopper, the acid should not be colored yellow within an hour. *After shaking equal volumes* of ethyl bromide and water, no change of volume should occur in the two liquids, the water separated from the ethyl bromide should not have an acid reaction nor should it become turbid immediately on the addition *of a* drop of silver nitrate solution (Pharm. Helvetica).

When a small portion is evaporated from a porcelain plate by causing it to flow to and fro over the surface little or no foreign odor *is yielded as* the last-portions pass off, and the plate is covered with a slight deposit of moisture.

1 Cc. of ethyl bromide mixed with 3 drops of anilin and 2 Cc. of alcoholic solution of potassium hydroxide should not give *off* the *odor* of isonitrile even after warming. (Absense of chloroform) (Pharm., Belgica.)

About 1 Gm. of ethyl bromide accurately weighed added to 30 Cc. of 80 per cent. alcohol containing 2 Gm. silver nitrate will precipitate, after several hours, silver *bromide*, which when washed and dried should weigh 1.72 Gm. for each Gm. ethyl bromide used (Pharm. Française).

Action and Uses.—Ethyl bromide is a rapid anesthetic, acting much like chloroform. The anesthesia is quickly and pleasantly induced and the recovery *is rapid*, but subsequently the patient may have general mild depression. Pain is abolished before consciousness. The respiration is paralyzed at about the same time as the reflexes, so that the zone of safety is very narrow. Tetanic spasms have occurred. Deaths were formerly attributed to impurities, but several have occurred when a pure article was given. It has been recommended for short operations in obstetrics, gynecology and *minor* surgery, but is not to be used for long operations. It must be regarded as a very dangerous agent in inexperienced hands.

Dosage.—3 Cc. to 12 Cc. (45 minims to 3 fluidrams) is sufficient *to induce* anesthesia. It should be administered rapidly with little or no air. The administration requires from 20 to 40 seconds; the anesthesia lasts about two *minutes*. The dose for children should not exceed 1 Cc. per year *of* age.

It should be protected from the *light and* a *bottle once* opened should be used at once, as it *deteriorates* rapidly. (To be preserved carefully in small, opaque bottle containing not more than 50 Cc. Pharm. Helvetica, edit. 4.) *It should* not be confounded with ethylene bromide, which is said to be very poisonous. The Sp. Gr. of ethylene bromide is 2.179, while that of ethly bromide is about 1.45

ETHYL CARBAMATE

Ethyl Carbamate is official in the United States Pharmacopeia. For description see the Pharmacopeia or the Physician's Manual of the Pharmacopeia and National Formulary.

URETHANE.—A name applied to Æthylis Carbamas, U. S. P.

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York).

URETHAN-Hoechst.—A name applied to Aethylis Carbamas, U. S. P.

Manufactured by Farbwerke. vorm. Meister Lucius & Bruening, Hoechst a. M., Germany (Victor Koehl & Co., New York). Not patented or trademarked.

ETHYL CHLORIDE

Ethyl Chloride is official in the United States Pharmacopeia. For description see the pharmacopeia or the Physician's Manual of the Pharmacopeia and National Formulary.

KELENE.—A name applied to Æthylis Chloridum, U. S. P., supplied in a special form of container.

Manufactured by Fries Bros., New York.

ETHYL SALICYLATE—Æthylis Salicylas.—Ethyl salicylate $C_6H_4.OH.COO(C_2H_5)=C_9H_{10}O_3$. is the salicylic acid ester of ethyl alcohol and is analogous to methyl salicylate (oil of wintergreen).

It is made by the action of salicylic acid on ethyl alcohol in the presence of sulphuric acid and subsequent purification.

It is a transparent, colorless, volatile liquid, possessing a pleasant characteristic odor and taste. Its sp. gr. is 1.184 at 20° C. (68° F.) and it boils at 231.5° C. (448.7° F.). It is insoluble in water, but soluble in alcohol.

Actions and Uses.—Ethyl salicylate has the same action as the salicylates, but is said to be less toxic.

Dosage.—3 to 6 c.c. (5 to 10 minims) 3 or 4 times a day.

Proprietary Preparation:

SAL ETHYL.—A name applied by Parke, Davis & Co., Detroit, Mich., to their preparation of ethyl salicylate, which is marketed in gelatin globules containing 0.33 Cc. (5 minims) each. U. S. trademark.

ETHYLENEDIAMINE. — Æthylendiamin — Æthylene Diamine — Ethane Diamine — *a.b.*Diamino-Ethane. — Ethylenediamine. is 1,2-diamino-ethane, $CH_2(NH_2).CH_2(NH_2)=C_2H_8N_2$.

It is prepared by heating 1.2-dibrom-ethane, ethylene bromide, with an excess of alcoholic ammonia, for 12 hours at 100° C. (212° F.), removing the ammonium bromide formed by filtration, evaporating the filtrate to dryness, distilling the residue with potassium hydroxide, and collecting the fraction distilling between 115° and 130° C. (239° to 266° F.) and bringing the liquid by successive purifications to a constant boiling point at 117° C. (242.6° F.).

It is a clear, colorless, thick liquid, having a sp. gr. 0.97 boiling at 117° C. (242.6° F.), without decomposition, having a strong alkaline reaction, an ammoniacal odor and a caustic taste. It is freely soluble in water, and may be mixed with cresols, but is not miscible with benzene (benzol) or ether. It dissolves albumin, even when boiled, very readily.

Being a strong base its incompatibilities are about the same as those of sodium hydroxide.

Actions and Uses.—It is said to be non-corrosive and useful as an albumin solvent for the solution of false membranes in diphtheria and similar affections of the mucous membranes. It is presented for use in the form of kresamine (which see).

Proprietary Preparation:

ETHYLENEDIAMINE SOLUTION, 10 Per Cent.—A solution containing 10 per cent. ethylenediamine (which see).

Actions and Uses.—See ethylenediamine.

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin. Germany (Schering & Glatz, New York).

ETHYLENEDIAMINE PREPARATIONS

KRESAMINE.—*Ethylene-Diamine Trikresol.*—Kresamine is a clear watery solution of 25 per cent. of trikresol (which see) and 25 per cent. of ethylene-diamine.

It is a clear, colorless liquid, miscible in all proportions with glycerin, and soluble to the extent of about 20 per cent. in water, but insoluble in petrolatum.

Actions and Uses.—Kresamine is a bactericide, with a claimed minimum of toxicity. It is said that the bactericidal effect of the cresol and its power of penetrating the animal tissues are greatly enhanced by the presence of ethylenediamine and it is claimed to be less irritating when used as a wet dressing than other antiseptics. It is said to be useful in all cases where an active bactericide is required and particularly when microbes are in an albuminous menstruum. The preparation is not so dangerous as carbolic acid. It has been employed for the treatment of ulcers, eczema, lupus and other skin affections.

Dosage.—It is used only in dilutions (2 to 25) containing 2 per cent. or less of each of its active constituents.

Kresamine may be applied in the form of ointment.

A dilution containing 2 per cent. of each ingredient was formerly marketed under the name "Ethylene-diamine Trikresol Solution." This was used without dilution.

Prepared by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin, Germany (Schering & Glatz, New York). German patent No. 74,634.

EUCAINE

The "Eucaines" are two closely allied synthetic bases, differentiated as eucaine "A" and eucaine "B." or "Alpha-eucaine" and "Beta-eucaine" alpha-eucaine being a synthetic derivative of triacetonamine, while beta-eucaine is a synthetic derivative of vinyl-diacetone-alkamine.

Alpha-Eucaine Hydrochloride has been withdrawn from the American market by the agents, Schering & Glatz, New York.

BETA - EUCAINE HYDROCHLORIDE — Beta - Eucainæ Hydrochloridum.—*Trimethylbenzooxypiperidinum Hydrochloricum* (Pharm. Helvetica edit. 4). Eucainum Hydrochloricum β (Pharm. Hungarica, edit. 3). Chloretum Eucaicum (Pharm. Danica, 1907). Eucaine Hydrochloride β. Beta-eucaine hydrochloride. $C_5H_7N(CH_3)_3(C_6H_5COO).HCl$, is 2,6,6-trimethyl-4-benzoxy-piperidine hydrochloride.

It is prepared by treating diacetonamine with paraldehyde, reducing the product with metallic sodium, benzoylating the vinyl-diacetonalkamine (melting at 138° C.) so produced by treatment with benzoylchloride, neutralizing the resulting benzoyl-vinyl-diacetonalkamine (trimethyl-benzoxypiperidin) with hydrochloric acid and crystallizing.

It forms a white crystalline powder, soluble in 20 to 30 parts of water at the ordinary temperature, but more soluble in warm water, soluble in 25 to 30 parts of alcohol, producing neutral solutions which can be sterilized by boiling without change. The aqueous solutions yield ether soluble precipitates of the free base on addition of alkali hydroxides or carbonates. Ammonia water produces a precipitate which redissolves, but is reprecipitated on the addition of more ammonia.

The saturated aqueous solution gives no precipitate with mercuric chloride, which distinguishes it from the corresponding alpha-eucaine salt. It gives no color reactions with sulphuric or nitric acid, but yields a yellow precipitate with chromic acid, orange yellow with bismuth-potassium iodide, lemon yellow with picric acid and a white precipitate with phosphomolybdic acid. It is incompatible with alkalies and their carbonates.

If to a solution of 0.1 Gm. of beta-eucaine hydrochloride in 20 Cc. of water 1 drop of ammonia water (10 per cent.) is added. a white precipitate is produced which gradually disappears on shaking. If 3 drops more or ammonia water are added, a precipitate again occurs which dissolves on the addition of 20 Cc. of water. Further addition of ammonia produces a precipitate which is again dissolved on the addition of 10 Cc. of water. If to this liquid ammonia is again added no precipitate occurs, but merely a milky turbidity which disappears on the addition of water.

Beta-eucaine hydrochloride dissolves in sulphuric acid without color.

If 1 drop of a 1 per cent. solution is mixed with 1 drop of mercuric chloride test solution, no precipitate should occur (absence of cocaine and alpha-eucaine).

0.1 Gm. of beta-eucaine hydrochloride should leave no weighable residue on incineration.

Quantitative Determination: 0.5 Gm. eucaine hydrochloride is dissolved in 100 Cc. of alcohol. This solution is titrated with tenth normal sodium hydroxide solution, using phenolphthalein as indicator. 1 Cc. tenth normal sodium hydroxide solution= 0.0269 Gm. of eucaine hydrochloride. Instead the alkaloid may be extracted with chloroform from the aqueous solution made alkaline with ammonia water, the chloroform allowed to evaporate spontaneously, the residue dried in a desiccator, and weighed. The alkaloid should weigh 86.56 per cent. of the weight of the salt.

Actions and Uses.—Beta-eucaine hydrochloride is a local anesthetic like cocaine, but weaker and devoid of the stimulating properties of the latter. It does not dilate the pupil, nor does it contract the blood vessels as does cocaine. It has the advantage of stability even on prolonged boiling. It may be used in all cases in which cocaine is indicated as a local anesthetic, especially in ophthalmology.

Dosage.—It may be applied in a 2 to 3 per cent. solution to the eye, 5 to 10 per cent. for nose and throat and 5 to 10 per cent. for ointment for hemorrhoids.

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin, Germany (Schering & Glatz, New York). U. S. patent No. 657,880 (Sept. 11, 1900; expires 1917). German patent No. 97,672.

BETA-EUCAINE LACTATE—Beta-Eucainæ Lactas.—Beta-eucaine lactate, $C_5H_7N(CH_3)_3(C_6H_5COO).C_3H_6O_3$, is 2,6,6-trimethyl-4-benzoxy-piperidine lactate.

It is prepared in a manner similar to the method for beta-eucaine hydrochloride, lactic acid being substituted for hydrochloric.

Beta-eucaine lactate forms a white crystalline powder soluble in about 5 parts of water at the ordinary temperature in 10 parts alcohol and in 5 parts chloroform and in fatty oils with the aid of chloroform. It melts at about 152° C. (305.6° F.). The aqueous solution is feebly alkaline to litmus. In aqueous solutions the base can be thrown down by solutions of sodium or potassium hydroxide as an oily deposit which solidifies after a time. Ammonia produces a precipitate which redissolves, but is reprecipitated on the addition of more ammonia.

Tests: The precipitate caused by 4 drops of ammonia water (10 per cent.) in a solution of 0.1 Gm. of beta-eucaine lactate in 20 Cc. of water is redissolved on the addition of 20 Cc. of water.

If a few drops of diluted sulphuric acid and 1 Cc. of potassium bichlorate solution (1:10) are added to 0.1 Gm. of eucaine lactate, heating develops an odor of acetaldehyde.

0.1 Gm. of eucaine lactate should dissolve without coloration in 1 Cc. of cold sulphuric acid (sp. gr. 1.84). 0.2 Gm. of eucaine lactate, on combustion, should leave no weighable residue.

Quantitative Determination: 0.5 Gm. eucaine lactate is dissolved in 100 Cc. of alcohol. This solution is titrated with tenth-normal sodium hydroxide solution, using phenolphthalein as indicator. 1 Cc. tenth-normal sodium hydroxide solution = 0.0323 Gm. of eucaine lactate. Instead the alkaloid may be extracted with chloroform from the aqueous solution made alkaline with ammonia water, the chloroform allowed to evaporate spontaneously, the residue dried in a desiccator, and weighed. The alkaloid should weigh 72.30 per cent. of the weight of the salt.

Actions and Uses.—The same as those of beta-eucaine-hydrochloride, over which it possesses the advantage of greater solubility.

Dosage.—For hypodermic injections, 2 to 4 per cent. solutions (preferably in 0.6 to 1.0 per cent. sodium chloride solution with or without epinephrine); in the eye, 1 to 2 per cent. solutions; for penciling or tamponading mucous membranes, 10 to 15 per cent. solutions; for infiltration, 1 to 500 solutions with sodium chloride 0.6 to 1 per cent. and epinephrine; for painful wounds, 5 to 10 per cent. ointments with wool fat (adeps lanæ).

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin, Germany (Schering & Glatz, New York). U. S. patent No. 657,880 (Sept. 11, 1900; expires 1917).

EUGALLOL.—Eugallol is a solution consisting of two parts of monoacetylpyrogallol, $C_6H_3(OH)_2(CH_3COO)$, and one part of acetone.

It is prepared by treatment of pyrogallol with acetic anhydride or acetyl chloride, in the presence of a solvent and subsequent removal of the solvent by distillation. It is also obtained by other methods.

Actions and Uses.—Eugallol acts as an energetic substitute for pyrogallol, but is liable to produce local irritation when applied to the skin.

It is said to be useful externally in old and persistent cases of psoriasis.

Dosage.—It is applied pure by penciling once a day, covering the painted part with powdered zinc oxide, suspending the application a few days if it is followed by irritation.

Manufactured by Knoll & Co., Ludwigshafen a. Rh., Germany, and New York. German patent No. 104,663.

EUMYDRIN — Methylatropinæ Nitras. — Atropinmethyl Nitrate.—Eumydrin, $C_6H_5(HO.CH_2)CH.CO_2.C_7H_{11}N(CH_3)_2NO_3 = C_{18}H_{26}O_6N_2$, is the nitrate of methylated atropine.

It is obtained by the interaction of methyl-atropine halide with metallic nitrates, or by treatment of the methyl atropine base with nitric acid, by interaction of atropin with methyl nitrate and by other patented processes.

It is a white, crystalline salt, melting at 163° C. (325.4° F.), odorless, permanent and readily soluble in water or alcohol, but very sparingly soluble in ether or chloroform. A quantity of 100 parts contains atropin equivalent to about 90 parts of atropine sulphate.

On warming 0.01 Gm. of eumydrin with 1.5 Cc. of sulphuric acid until the solution begins to darken, and at once adding, carefully, 2 Cc. of water a violet color develops and at the same time a faint peculiar aromatic odor appears. A solution of 0.05 Gm. of eumydrin in 3 Cc. of water, remains clear on the addition of either 1 Cc. of sodium hydroxide solution or of ammonia water.

Being an alkaloidal salt it is incompatible with alkaline solutions, etc.

Actions and Uses.—Eumydrin is a mydriatic and antihidrotic, replacing atropine sulphate both internally and externally in corresponding doses. It is claimed that it dilates the pupil more rapidly than atropine and the dilatation is of shorter duration—being intermediate in these respects between atropine and homatropine. It is said to be much less toxic than atropine, so that larger doses may be given to secure the effect. It is said to be particularly useful for the treatment of night sweats, whooping cough and for the relief of enuresis.

Dosage.—Internally as an antihidrotic, 0.001 to 0.0025 Gm. (1/60 to 1/24 grain). Externally as mydriatic, in solutions about one-tenth stronger than the usual atropine solutions.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). German patent Nos. 137,622 and 138,443.

EUPHORIN—Æthylis Phenylcarbamas.—Phenyl Urethane—Phenylethylurethane—Phenylcarbamic Acid Ethyl Ester.—Euphorin, $CO(NH.C_6H_5)(OC_2H_5) = C_9H_{11}O_2N$, is a compound closely allied to Æthylis Carbamas, U. S. P. (urethane) and differing from this by the replacement of the group NH_2 by NHC_6H_5.

It is prepared by the action of aniline on chlorformic acid ethyl ester.

It forms colorless needles or a white powder, melting at 50°-51° C. (122° to 123.8° F.), having a faint aromatic odor and clove-like taste. It is almost insoluble in water, readily soluble in diluted alcohol, in alcohol and in ether.

Actions and Uses.—Euphorin is anodyne, antipyretic and antiseptic.

It is said to be useful in rheumatism, sciatica, headache, etc. Externally it is recommended to be applied as a dusting powder in venereal and skin diseases, ulcers, burns, etc.

Dosage.—0.5 to 1 Gm. (8 to 15 grains) dissolved in wine or suspended in water; externally in powder, in lanolin ointment and in superfatted soap.

Manufactured by Fabrik von Heyden, Radebeul near Dresden, Germany. U. S. trademark.

EUPHTHALMIN—Euphthalmine Hydrochloride—Phenylglycolyl-Methyl-Vinyl Diacetonalkamine Hydrochloride.—Euphthalmin, is 1,2,6,6-tetramethyl-4-mandeloxy-piperidine hydrochloride, $C_5H_6N(CH_3)_4(C_6H_5.CHOH.COO).HCl$. It is closely related to trimethyl-benzoxy-piperidine hydrochloride (see Beta Eucaine Hydrochloride).

It is prepared by methylating [illegible] [illegible] hydrochloric acid into the solu- [illegible] its ether solution.

Actions and Uses.—Euphthalmin produces prompt mydriasis free from anesthetic action, pain, corneal irritation, or rise in intraocular tension. It has little or no effect on accommodation, and this disappears more rapidly than with atropine, cocaine, homatropine, etc. In its effects on the general system, euphthalmine very closely resembles atropine.

It is useful as an aid in ophthalmoscopic examinations in place of atropine, homatropine, etc.

Dosage.—2 or 3 drops of a 5 to 10 per cent. solution, according to age of the patient and the nature of the case, are instilled into the eye.

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin, Germany (Schering & Glatz, New York). U. S. patent No. 663,754 (Dec. 11, 1900; expires 1917). U. S. trademark No. 35,541.

EUPYRINE. — Vanillin-Ethylcarbonate-Para-Phenetidin.—Eupyrine, $C_6H_4(OC_2H_5)N:[CH.C_6H_3(O.CO.OC_2H_5)(OCH_3)]$ 1:4 $= C_{19}H_{23}O_5N$ is a compound of para-phenetidin, differing from acet-phenetidine in that the acet-amino group, $NH(CH_3CO)$, is replaced by the group, $N:[CH.C_6H_3(O.CO.OC_2H_5)(OCH_3)]$.

It is prepared by the action of vanillin ethyl-carbonate, $C_6H_3(COH)\ O.CH_3)\ (O.CO.OC_2H_5)$ 1:3:4 on an equivalent amount of para-phenetidin, $C_6H_4(O.C_2H_5)(NH_2)$ 1:4. Chemically it differs from acetphenetidin (phenacetin) in that the vanillin ethyl-carbonate group has replaced the acetyl group of acetphenetidin.

It occurs in light yellow, needle-shaped crystals, melting at 87° to 88° C. (188.6° to 190.4° F.); tasteless, with faint odor of vanillin. It is insoluble in cold water, sparingly soluble in warm water and in cold alcohol, readily soluble in warm alcohol and in ether or chloroform.

Concentrated sulphuric acid is colored by eupyrine greenish yellow in the cold and dark brown on heating to the boiling point. Heated on platinum foil it burns without residue. Acids and alkalies decompose it.

Actions and Uses.—The toxic action of phenetidin is said to be counteracted in eupyrine by the vanillin. Doses twenty times as great as those used for man show no production of an amount of methemoglobin recognizable by the spectroscope. It is claimed to be a stimulant antipyretic.

Eupyrine is claimed to be useful as an antipyretic, especially for patients with a weak stomach or otherwise sensitive, on account of its freedom from side effects. *For internal use it is open to the same objections as the other coal tar derivatives* (see Acetphenetidin).

Dosage.—For adults, 1.5 Gm. (23 grains) once or twice daily. It can be given by itself as a powder.

Manufactured by Vereinigte Chininfabriken, Zimmer & Co., Frankfort a. M., Germany. (C. Bischoff & Co., New York.) U. S. patent No. 658,446 (Sept. 25, 1900; expires 1917). U. S. trademark No. 39,577.

EURESOL.—Resorcin Monacetate.—Euresol is resorcinyl acetate, $C_6H_4(OH)(CH_3COO) = C_8H_8O_3$, the acetic acid ester of resorcinol, $C_6H_4(OH)_2$,1:4.

It is obtained by acting on resorcinol with acetic anhydride or acetyl chloride, $C_6H_4(OH)_2 + CH_3COCl = C_6H_4(OH)(CH_3COO) + HCl$ or by otherwise replacing one hydroxyl group in resorcinol with an acetyl group.

It is a thick, honey-yellow, oily liquid, having an agreeable odor, boiling at 283° C. (541.4° F.) and soluble in acetone.

Actions and Uses.—Its action is similar to that of resorcinol, but milder and more lasting because of the gradual liberation of the phenol.

Euresol is said to be useful in acne, sycosis, seborrhea, and particularly in the treatment of chilblains.

Dosage.—It is applied in 5 to 20 per cent. ointments and in acetone solution.

Manufactured by Knoll & Co., Ludwigshafen a. Rh., Germany, and New York. German patents Nos. 103,857 and 122,145.

Euresol Soap.—A soft soap, supplied in tubes, containing euresol, eucalyptol and oil of turpentine.

EUROPHEN — Di-Isobutyl-Cresol Iodide. — Europhen, $C_6H_3(C_4H_9)(CH_3)(OI).C_6H_2(CH_3)(:O)(.C_4H_9) = C_{22}H_{29}O_2I$, is a condensation product of 2 molecules of isobutylorthocresol, *with 1 atom of iodine, analogous to Thymolis Iodidum, U. S. P.*

It is prepared by the addition of a solution of iodine in potassium iodide to an alkaline solution of isobutylcresol, washing the precipitate with water, and drying it at a moderate temperature.

It forms a yellow, voluminous powder, fusing at 110° C. (230° F.), containing 28 per cent. of iodine, and having a faint saffron-like odor. It is insoluble in water or glycerin, but readily soluble in alcohol, ether, chloroform and the fixed oils. It is permanent in the dry state, but splits off iodine readily when moistened and rapidly when heated with water at 70° C. (158° F.), particularly in the presence of alkalies.

When triturated with glycerin and water, it yields a filtrate which is turned bluish by the addition of freshly prepared starch paste. Its alcoholic solution produces a yellow precipitate with mercuric chloride.

It should not be exposed to heat, light or damp air; it is incompatible with starch, metallic oxides, mercuric salts, and alkaline hydrates and carbonates.

Actions and Uses.—Its action is similar to that of iodoform and thymol iodide. It is claimed to be useful especially in the treatment of venereal ulcerations.

Dosage.—Europhen may be given internally in the form of pills in doses of from 0.2 to 0.3 Gm. (3 to 5 grains). Locally it may be used as a dusting powder in substance or mixed with an equal quantity of finely powdered boric acid, as an ointment, with wool fat (lanolin), or as a 5 per cent. embrocation, dissolved in olive oil.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 495,204 (expired); German patent No. 56,830. U. S. trademark No. 17,888.

EXODIN.—Exodin is a mixture of derivatives of rufigallic acid (*hexahydroxy-anthraquinone*). It contains diacetyl rufigallic acid tetra-methyl ester, acetyl-rufigallic acid pentamethyl ester and rufigallic acid hexa-methyl ester.

According to the patent it is obtained by treating rufigallic acid tetra-methyl ester with acetic anhydride and sodium acetate and purifying the product by crystallization.

Actions and Uses.—Exodin is claimed to be a pleasant and reliable cathartic. It is said to produce a mild and protracted tonic effect on the digestive tract and to produce neither gastric pains nor colic.

Exodin is claimed to be useful in acute and chronic constipation of the atonic form and also in cases in which regular evacuation of the bowels must be stimulated in consequence of hemorrhoids, etc.

Dosage.—For children, 0.5 Gm. (7½ grains); adults, 1 to 1.5 Gm. (15 to 22 grains) in tablets or in powder stirred up with water.

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin, Germany (Schering & Glatz, New York). U. S. patent No. 751,216 (Feb. 2, 1904; expires 1921). U. S. trademark No. 43,029.

FERRATIN—Sodii Ferrialbuminas.—Sodium Ferrialbuminate.—*Ferratin is the sodium salt of ferrialbuminic acid*, containing iron in the ferric state in organic combination, equivalent to 6 per cent. metallic iron.

Sodium ferrialbuminate occurs naturally in the organs of mammals, especially in the liver Ferratin is prepared from egg albumin and chemically pure iron salts in the presence of alkalies.

Ferratin is a light brown, tasteless powder, having a faint odor. It is soluble in weak alkaline aqueous solutions, from which solutions it is precipitated by hydrochloric acid. On dissolving 0.3 Gm. ferratin in 10 Cc. of water with the aid of a few drops of ammonia water, and then adding an equal volume of a 25 per cent. potassium carbonate solution, no precipitation occurs.

Actions and Uses.—See Organic Iron Compounds.

Dosage.—0.5 Gm. (7½ grains) three to four times daily.

Manufactured by C. F. Boehringer & Soehne, Waldhof, Mannheim, Germany. (Merck & Co., New York). U. S. patent No. 505,986 (expired). U. S. trademark No. 24,228.

FERRIC ARSENITE, SOLUBLE—Ferri Arsenis Solubilis.—Ferric Arsenite and Ammonium Citrate.—Soluble Ferric Arsenite is Ferric Arsenite made soluble by the addition of ammonium citrate.

Soluble ferric arsenite occurs in green scale, easily soluble in water; it contains 1.06 per cent. arsenic, equivalent to 1.4 per cent. arsenous oxide, and iron, equivalent to from 15 to 18 per cent. elementary iron.

Actions and Uses.—Soluble ferric arsenite is a hematinic said to be particularly indicated in anemia complicated with malaria, in pernicious anemia and in pellagra.

Dosage.—0.03 to 0.065 Gm. (½ to 1 grain). It may be given by subcutaneous injections in the gluteal region in doses of 0.03 Gm. (½ grain) dissolved in 1 Cc. (15 minims) of water every two or three days.

Non-Proprietary Preparations:

Ampules Iron Arsenite Solution S. & D.—Each ampule is said to contain soluble iron arsenite, 0.06 Gm. (1 grain), dissolved in 1 Cc. (16 minims) of distilled water, representing closely 0.00092 Gm. (1/70 grain) of arsenic trioxide and 0.0092 gm. (1/7 grain) of metallic iron.

Prepared by Sharp & Dohme, Baltimore, Md.

FERRO-MANGAN Dieterich—Liquor Ferro-Mangani Peptonati "Dieterich."—Ferro-mangan is a solution of a compound of peptone with iron and manganese, containing 0.6 per cent. *of iron, 0.1 per cent. of manganese* and 1.5 per cent. of peptone.

It is prepared by covering 40.0 Gm. of iron and manganese peptonate "Dieterich" with distilled water for one hour, then heating to boiling with 550.0 Cc. of distilled water and allowing to cool. An aromatic mixture is added consisting of 100.0 Cc. cognac, 75.0 Cc. alcohol, 90 per cent., 0.25 Gm. saccharin, 12.5 Cc. aromatic tinctures, and sufficient distilled water to make 1000.0 Cc.

Ferro-mangan is a clear liquid of a dark-brown color and pleasant odor and taste. It is slightly acid in reaction.

The iron is in the organic or non-ionic form (see "Organic Iron preparations").

Method of Valuation: The specific gravity at 15° C. (59° F.) should be about 1.056. The percentage of dry residue at 100° C. (212° F.) varies between 13.25 and 16.80. The percentage of residue after ignition varies between 0.99 and 1.05. The percentage of iron and manganese determined by well-known methods varies between 0.58-0.64 per cent. of iron and 0.13-0.19 per cent. of manganese.

Actions and Uses.—It has the actions of iron and manganese.

It is said to be useful in anemia, chlorosis, convalescence and as a general tonic.

Dosage.—4 to 16 Cc. (1 to 4 fluidrams), according to age, three times a day.

Manufactured by Chemische Fabrik Helfenberg A. G., near Dresden, Germany (The Reinschild Chemical Co., New York). Not patented or trademarked.

FERROUS LACTATE—Ferri Lactas.—Iron Lactate—Ferrum Lacticum. (U. S. P., 1890; Pharm. Germanica, edit. 4; Pharm. Helvetica, edit. 4; Pharm. Belgica, edit. 3; Pharm Francaise, 1908); Ferrous lactate, $Fe(C_3H_5O_3)_2 + 3H_2O$ is the ferrous salt of lactic acid. The salt contains approximately 19 per cent. of metallic iron.

Ferrous lactate occurs in pale greenish-white crusts, consisting of small needle-shaped crystals, or transparent green scales, having a slight, peculiar odor and a sweetish, ferruginous taste.

It is slowly soluble in about 40 parts of cold, and in 12 parts of boiling water; almost insoluble in alcohol; freely soluble in a solution of an alkali citrate yielding a green solution.

When strongly heated the salt froths, gives out dense, white, acid fumes, chars and finally leaves a brownish red residue.

The aqueous solution of the salt has a greenish-yellow color, a slighly acid reaction, and gives a deep blue precipitate with potassium ferricyanide, and a light blue one with potassium ferrocyanide.

A 2 per cent. aqueous solution of the salt should not yield more than a faint opalescence with a solution of lead acetate (limit or absence of sulphate, chloride, citrate, tartrate and malate). The aqueous solution after acidulation with hydrochloric acid should not yield any precipitate or coloration when treated with hydrogen sulphide (absence of foreign metals).

The aqueous solution, acidulated with nitric acid, should not afford more than a slight opalescence with barium chloride solution or with silver nitrate solution (limit of sulphate or chloride). If 25 Cc. of a 2 per cent. aqueous solution of the salt be mixed with 5 Cc. of diluted sulphuric acid, the mixture boiled for a few minutes, an excess of sodium hydroxide added and the mixture filtered, the filtrate when mixed with a few drops of alkaline cupric tartrate solution and boiled, should not yield a red precipitate (absence of sugar).

If a portion of the salt be triturated with strong sulphuric acid no offensive odor should be developed (absence of butyric acid), nor should any gas be evolved (absence of carbonate), and the mixture after standing for some time should not assume a brown color (absence of sugar, gum, or other readily carbonizable impurities).

If 1 Gm. of the salt, contained in a porcelain crucible, be moistened with nitric acid and carefully ignited, it should leave a residue of ferric oxide weighing not less than 0.270 nor more than 0.278 Gm. This residue should not have an alkaline reaction on litmus paper, nor yield anything soluble to water (absence of foreign salts).

Actions and Uses.—Ferrous lactate is a mild chalybeate which because of its feeble taste may be taken without difficulty.

Dosage.—0.06 to 1.3 Gm. (1 to 20 grains). Owing to its liability to oxidation, it is best prescribed in solutions containing much sugar. Syrup dissolves 1 Gm. in 120 Gm. (4 grains to the fluidounce).

FILICIC ACID AND RELATED SUBSTANCES

Aspidium and pharmaceutical preparations thereof have long been used as teniafuges. The most recent work indicates that aspidium probably contains the following constituents, in approximately the amount indicated: Filicic acid, 3.5 per cent.; flavaspidic acid, 2.5 per cent.; albaspidin, 0.05 per cent.; aspidinol, 0.10 per cent.; flavaspidin, 0.10 per cent.; amorphous acid, 5.0 per cent. and filicic nigrine, 6.0 per cent. These substances are, for the greater part, derivatives of phloroglucinol, and some of them are ketones possessing acid characters.

The various formulas assigned to the filicic acids and the different results reported regarding their physiological activity, have given rise to much confusion, leaving the chemistry in an unsettled condition. One of the first formulas assigned to filicic acid is that of Luck—$C_{26}H_{30}O_9$, which differs considerably from the formula—$C_{14}H_{18}O_5$—given this substance by Grabowski and $C_{14}H_{16}O_5$, as suggested by Daccoma. Later two forms, a crystalline and an amorphous filicic acid, were recognized by Poulson, who suggested the formula, $C_{36}H_{40}O_{12}$ for the crystalline filicic acid and $C_{36}H_{42}O_{13}$ for the amorphous acid, which latter he considered as the active therapeutic principle of aspidium. Poulson believed the crystalline acid to be the anhydride of the amorphous acid. More recently, Gallas has stated the formula for both the crystalline and the amorphous filicic acid to be $C_{14}H_{22}O_6$. Gallas and later Kraft concluded that one form of the acid was the lactone of the other form. Filicinic acid, which has the formula ($C_8H_{10}O_3$) is sometimes confused with filicic acid. Besides a difference in the theories regarding the constitution of the various filicic acids, there has been considerable controversy over the anthelmintic properties of these substances.

Our knowledge of the subject is very imperfect, but the majority of authors still accept filicic acid as one of the active constituents of aspidium.

FILICIC ACID, AMORPHOUS.—Acidum Filicicum Amorphum.—Amorphous filicic acid is an organic acid $C_{36}H_{42}O_{13}$, obtained from several species of aspidium.

Amorphous filicic acid is a white, or yellowish powder, without odor or taste, melting at 125° C. (257° F.), soluble in cold alcohol.

Actions and Uses.—Amorphous filicic acid has been recommended as an anthelmintic, and is generally considered one of the active principles of several species of aspidium.

Dosage.—0.5-1.0 Gm. (8 to 15 grains) given with calomel or calomel and jalap.

Note:—The crystalline filicic acid, also designated as filicinic acid, which is considered as an anhydride of the amorphous, is devoid of anthelmintic action, and must not be used in place of the amorphous.

FILMARON.—Filmaron, $C_{47}H_{54}O_{16}$, is an active anthelmintic constituent obtained from the ethereal extract of aspidium (the rhizome of Dryopteris Filix Mas).

Filmaron is obtained from the male fern extract by isolating it in the form of a metallic salt, from which the free filmaron is liberated and suitably purified.

Filmaron occurs as a straw-colored amorphous powder, insoluble in water, difficultly soluble in ethyl and methyl alcohols, and rather difficultly soluble in petroleum ether. It is readily soluble in all proportions in ether, acetic ether, amyl alcohol, chloroform, benzine, carbon disulphide, and acetone, and also, though with partial decomposition, in solutions of the alkalies and alkali carbonates. The alcoholic solution exhibits a slightly acid reaction. Filmaron melts at about 60° C. (140° F.). It exhibits a strong tendency to cake together to form a resinous mass, which is difficult to reduce to powder and dispense; hence it is not marketed in substance, but as a 10 per cent. castor oil solution, which is known as "Filmaron oil."

0.5 Gm. filmaron and 5 Gm. pumice stone, and 1 Gm. magnesia are finely triturated with 250 Cc. water, the mixture shaken for half an hour, and then filtered. On passing a rapid current of carbon dioxide through the filtrate a voluminous, flocculent precipitate forms; the filtrate should afford but very slight precipitate on the addition of hydrochloric acid.

On dissolving 0.1 Gm. filmaron in 0.2 Gm. acetic ether or 0.2 Gm. carbon disulphide by rotation in a test tube, and setting the stoppered tube aside for three days, no separation should have taken place at the end of this time (absence of other male fern constituents; filicic acid and flavaspidic acid).

0.1 Gm. filmaron should completely dissolve in 0.5 Gm. warm petroleum ether, and leave no more than a slight trace of undissolved substance. To detect the filmaron in the castor oil solution (filmaron oil), dilute the filmaron oil with ether, shake out with sodium hydroxide solution, acidulate the alkaline liquid, and then take up the liberated filmaron with ether. On evaporating the ether the filmaron is obtained as a residue.

Actions and Uses.—Filmaron is said to exhibit the specific action of male fern extract and to be useful as an anthelmintic for expelling intestinal parasites.

It is claimed to be devoid of the injurious side actions sometimes exhibited by the oleoresin of male fern and to be harmless when given in the dose necessary for the expulsion of tape worm.

Dosage.—See Filmaron Oil.

Manufactured by C. F. Boehringer & Soehne, Waldhof near Mannheim, Germany (Merck & Co., New York). U. S. trademark No. 40,558.

Filmaron Oil.—Filmaron oil is a 10 per cent. solution of Filmaron in castor oil.

Dosage: 10 Cc. (2½ fluidram).

FLUORESCEIN—Fluoresceinum. — Resorcinolphthalein (a term not strictly correct but commonly used), dioxyfluoran.—Fluorescein, $O:(C_6H_3OH)_2:C.C_6H_4.COO = C_{20}H_{12}O_5$, is the anhydride of fluoresceinic acid $O:(C_6H_3OH)_2:C(OH).C_6H_4(COOH) = C_{20}H_{14}O_6$.

Fluorescein is prepared by the fusion of phthalic anhydride and resorcinol at 195-200° C. (383-392° F.) till the mass becomes solid. This is extracted with water and the residue dissolved in potassium hydroxide solution, which is then filtered and the fluorescein precipitated with acid.

Fluorescein is an orange red powder, insoluble in water, ether, chloroform, and benzol; soluble in hot glacial acetic acid and boiling alcohol. It dissolves in alkaline solutions with formations of a salt

The alkaline solution by transmitted light is red; by reflected light it has a green fluorescence even in very dilute solutions. When fluorescein is boiled, with chalk and water, the calcium salt of fluorescein is formed which is recognized by its red brown color and green sheen.

Actions and Uses.—The soluble sodium salt of fluorescein (fluorescein 2 Gm., sodium bicarbonate 3 Gm., water to make 100 Cc.) has been used for the diagnosis of corneal lesions and detection of minute foreign bodies imbedded in the cornea. While a weak solution of fluorescein will not stain the normal cornea, ulcers or parts deprived of epithelium will become green and remain so for a time; foreign bodies will appear surrounded by a green ring; loss of substance in the conjunctiva is indicated by a yellow hue. Fluorescein also reveals defects or disease of the endothelium of the cornea, producing a deep coloration of the diseased area.

Non-Proprietary Preparation:

Tabloid (Ophthalmic) Fluorescein B.-W. & Co.—Each tablet contains fluorescin 0.00026 Gm. (1-250 grain) in combination with sodium, and weighs 0.0032 Gm. (1-20 grain).

Prepared by Burroughs-Wellcome & Co., London, England, and New York.

FORMIC ACID—*Acidum Formicum.*—Acidum formicum (Pharm. Helvetica, edit. 4; Pharm. Germanica, edit. 4).

Formic acid is a liquid containing 24-25 per cent. of anhydrous formic acid (HCOOH).

Formic acid is a clear colorless liquid possessing a sharp acid odor and taste. It has a specific gravity of 1.058-1.061. With lead acetate, formic acid produces a white crystalline precipitate. On warming with silver nitrate a gray turbidity and with mercuric chloride a white turbidity is produced. A solution (1-10) after the addition of a few drops of nitric acid should yield no precipitate with silver nitrate or barium chloride; and after neutralizing with ammonia water calcium chloride or hydrogen sulphide should produce no precipitate. If 1 Cc. formic acid is mixed with 5 Cc. water and 1.5 Gm. mercuric oxide (yellow) and heated on the water bath there will follow an evolution of gas leaving a mixture which when filtered will yield a filtrate which should not react acid (acetic acid). Five Cc. formic acid should quire 27.6 Cc. to 28.8 Cc. normal alkali for neutralization, denoting a content of 24-25 per cent. by weight or 254-265 Gm. anhydrous formic acid per liter. The titrated solution should yield no burned or sharp odor (*Pharm. Helv. and Pharm. Germ.*).

Action and Uses.—The actions resemble those of acetic acid but it is more volatile, more irritant and more antiseptic Formic acid is much more resistant to oxidation, in the body than the other organic acid, and is therefore excreted to a large extent as formates, in the urine. These have an irritant action on the kidneys and urinary tract, and are diuretic Large doses cause methemoglobinemia, but the toxicity is quite low. It has no effect on the general circulation or on the motor system, as has been claimed. It has been lauded in a great variety of disorders, but there is no good evidence that its internal use produces any benefits other than psychical Its external use as a counterirritant is rational, but it possesses no special advantages.

Dosage.—Internally, 1-20 drops of the 25 per cent. acid, largely diluted; or 0.1-0.25 Gm. (1½-4 grains) of sodium formate. Externally usually in a solution containing 1 per cent. of the absolute acid in alcohol or diluted alcohol.

FORTOIN—Methylene-Dicotoin.—Fortoin, $CH_2(C_{14}H_{11}O_4)_2 = C_{29}H_{24}O_8$, is a condensation product of cotoin and formaldehyde.

It is prepared by condensation of cotoin and formaldehyde by means of dehydrating agents (hydrogen chloride): $2C_{14}H_{12}O_4 + CH_2O = CH_2(C_{14}H_{11}O_4) + H_2O$.

Fortoin forms yellow, needle-shaped, tasteless crystals, melting at 211° to 213° C. (411.8° to 415.4° F.) It is insoluble in water, sparingly soluble in alcohol, ether or benzol, but freely soluble in dilute alkalies, acetone or chloroform.

Fortoin dissolves in cold concentrated sulphuric acid with an orange color, and on warming the solution becomes ruby red. Heated on platinum foil it should burn without leaving any residue. On shaking with cold water or alcohol it should not yield any soluble constituents.

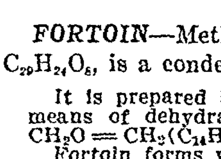
Actions and Uses.—Fortoin has an antiputrefactive, bactericidal action. It is said to cause an active, not passive, dilatation of the intestinal vessels by which the nutrition of the epithelium is improved and its regeneration hastened.

Fortoin is said to be useful as an antidiarrheic in acute and chronic intestinal catarrh and in the obstinate diarrheas due to pellagra and to tuberculosis. (See note under Beta-naphthol Benzoate.)

Dosage.—0.25 Gm. (4 grains) three times a day for adults.

Manufactured by Vereinigte Chininfabriken, Zimmer & Co., Frankfort a. M., Germany (C. Bischoff & Co., New York). German patent No. 104,362. U. S. trademark No. 39,523.

GALLOGEN—Ellagic Acid.—Benzoaric Acid.—Gallogen,



$$\begin{array}{c} C_6H(OH)_2 \\ CO \quad O \\ C_6(OH)_2.COOH \end{array} = C_{14}H_6O_8$$

is anhydrous ellagic acid prepared from Divi-divi, the pods of *Cæsalpina coriaria.*

It is prepared by prolonged boiling of an aqueous extraction of divi-divi, whereby the amorphous acid assumes a crystalline condition and is completely precipitated, then collecting the precipitate, washing and drying.

It is a yellowish, odorless, tasteless powder, insoluble in all acid and neutral liquids, but soluble in alkaline liquids to the amount of 2 per cent., such solutions being, however, very readily oxidized.

Its solutions in alkaline media give all the reactions of tannic acid with iron salts, gelatin solution, etc. With fuming nitric acid it gives a characteristic dark red color.

It is incompatible with alkaline liquids.

Actions and Uses.—Gallogen is an astringent and antidiarrheic, slowly decompose in the intestinal tract, thus exerting its astringent action gradually during its passage.

It is said to be useful in dysentery, cholera infantum, diarrhea, even in cases of a syphilitic or tuberculous origin.

Dosage.—0.3 to 0.5 Gm. (5 to 8 grains) for children; 0.6 to 1 Gm. (10 to 15 grains) for adults, suspended in neutral or slightly acid media.

Manufactured by Ad. Heinemann, Eberswalde, Germany (C. Bischoff & Co., New York). German patents Nos. 137,033 and 137,034.

GELSEMINE HYDROCHLORIDE—Gelseminæ Hydrochloridum.—Gelsemine hydrochloride is the hydrochloride of an alkaloid, $C_{24}H_{28}N_2O_4,HCl$ (*Gerrard*) ($C_{22}H_{26}N_2O_2$ by Spiegel, Ber. d. deut. Chem. Ges., vol. 26, p. 1054) derived from Gelsemium (Gelsemium sempervirens (L) Ait. f. Fam. Loganiaceæ).

Gelsemine hydrochloride occurs in prismatic crystals or a white crystalline powder. Soluble in water, but difficultly soluble in alcohol.

With concentrated sulphuric acid it gives a yellowish, and with concentrated nitric acid a *green coloration. If potassium* dichromate is introduced *into a solution of gelsemine in strong* sulphuric acid a cherry red coloration shading into violet which soon becomes green is produced at the point of contact.

Action and Uses.—Pure gelsemine appears to have a very slight toxic action, increasing reflex action in frog, to some extent, its action resembling strychnine. The effects of the commercial preparations are thought to be due to the gelseminine which they contain in varying quantities.

It has been used in neuralgia, especially trigeminal.

Dosage.—0.0005 to 0.002 Gm. (1/134 to 1/33 grain).

Note.—Gelseminine is a very poisonous alkaloid, found in gelsemium, which has an action very similar to that of coniine but is more depressant to the central nervous system, and must be carefully distinguished from gelsemine. Gelseminine is a mydriatic but is seldom used as such owing to its irritating action. Merck's "gelseminin" appears to consist of gelsemine and not gelseminine.

Gelsemine (Gerrard) is, according to Cushny (Proc. Am. Ph. Assn., Vol. 41, p. 850), the same as the German "crystallized gelsemine."

GLUTOL-Schleich.—Formalin Gelatin.—A chemical combination of gelatin and formaldehyde.

It is prepared by dissolving 500 Gm. of gelatin in 375 Gm. of water, adding 25 drops of formaldehyde solution, exposing the mass so obtained, in a covered box over lime, to the vapor of formaldehyde by the aid of a layer of cotton wool saturated with it until a dry mass is produced, and reducing this to powder.

It is a white, odorless powder, insoluble in water under ordinary conditions, but dissolved when heated with water under pressure, the solution thus produced gelatinizing on cooling. It is not changed by the action of acids, but is slowly decomposed in contact with living cells. It may be sterilized without decomposition.

Actions and Uses.—It is claimed that while in itself non-antiseptic, non-irritant and non-toxic, it becomes antiseptic and bactericidal in contact with living cells, in consequence of the elimination of nascent formaldehyde, which is split off very slowly but steadily.

Glutol is said to be useful as an odorless, non-irritant, non-poisonous aseptic dressing, having sustained antiseptic action for wounds, ulcers, burns, etc. (See note under Creosote Carbonate.)

Dosage.—It is employed undiluted as a dusting powder, etc.

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin, Germany (Schering & Glatz, New York). German patent No. 104,365. U. S. patent No. 572,295 (Dec. 1, 1896; expires 1913). U. S. trademark No. 28,431.

GLYCEROPHOSPHATES.

Glycerophosphates are the salts of glycerophosphoric acid, $H_2(CH_2OH.CHOH.CH_2)PO_4$.

The calcium compound is prepared by heating glycerin and phosphoric acid under certain conditions for a considerable time and then neutralizing with lime. The precipitated calcium phosphate is removed, while the calcium glycerophosphate remains in solution From the calcium salt the other salts can be prepared by precipitating calcium by the appropriate salt of the metal whose glycerophosphate is desired. Thus the addition of sodium carbonate to a solution of calcium glycerophosphate yields insoluble calcium carbonate and a solution of sodium glycerophosphate.

The potassium and sodium glycerophosphates are dense syrupy liquids, exceedingly soluble in water, and represent 75 per cent. of the respective salts in a dry condition. The calcium, iron, lithium, magnesium and manganese glycerophosphates are pulverulent salts, moderately soluble in water.

When a solution of glycerophosphate is tested by ammonium molybdate for the presence of a phosphate, only a slight yellow precipitate should form at once.

The watery solutions of glycerophosphates decompose in a short time. They should be made from sterilized water, but hot liquids should not be used for their preparation.

Actions and Uses.—These salts were introduced as "nerve foods" and tonics on the theory that their phosphorus, being a step nearer lecithin, is assimilated more readily than that of hypophosphites. Neither the experimental nor the clinical evidence is considered conclusive by all authorities.

Dosage.—The potassium and sodium salts may be given hypodermically 0.2 to 0.25 Gm. (3 to 4 grains) in normal saline solution, or *per os* 0.25 to 0.65 Gm. (4 to 10 grains) in water or syrup. The calcium, iron, lithium, magnesium and manganese salts 0.2 to 0.65 Gm. (3 to 10 grains) doses, preferably in the form of tablets; the quinine salt in 0.1 to 0.33 Gm. (1½ to 5 grains), and the strychnine salt in 0.001 to 0.003 Gm. (1/60 to 1/20 grain) doses.

TONOLS.—The name applied by E. Schering to identify glycerophosphates of his manufacture. See appendix, Schering & Glatz.

GUAIACOL COMPOUNDS.

Guaiacol Carbonate is official in the United States Pharmacopeia. For description see the pharmacopeia or the Physician's Manual of the United States Pharmacopeia and National Formulary.

DUOTAL.—A name applied to Guaiacolis Carbonas, U. S. P.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No 466,913 (expired). U. S. trademark.

DUOTAL-Heyden.—A name applied to Guaiacolis Carbonas, U. S. P.

Manufactured by Chemische Fabrik von Heyden, Radebeul, near Dresden, Germany (Schering & Glatz, New York). U. S. patent No. 466,913 (expired). U. S trademark No. 28,957.

BENZOSOL—Guaiacolis Benzoas.—Guaiacol Benzoate—Benzoyl-guaiacol. — Benzosol, $C_6H_4(OCH_3)(C_6H_5COO) = C_{14}H_{12}O_3$, is methoxy-benzoxy-benzene. It is closely related to guaiacol, $C_6H_4(OH)(CH_3)$, from which it differs in that the hydroxy-group is replaced by the benzoxy-group.

It is prepared by warming the potassium salt of guaiacol with benzoyl chloride and crystallizing the product from hot alcohol.

It forms colorless, minute crystals which melt at 59° to 61° C. (138.2° to 141.8° F.); they are odorless and tasteless or nearly so. It is practically insoluble in water, sparingly soluble in ether, but readily soluble in hot alcohol. It contains 54 per cent. of guaiacol.

It forms with sulphuric acid a permanent yellow coloration which on the addition of acetone assumes a characteristic, brilliant cherry red color, distinguishing it from salol, which gives a yellow color. Ferric chloride produces in the benzosol sulphuric acid mixture a violet color, changing to green and blue, and on the further addition of *nitric acid*, to orange and green, or of potassium nitrite to green, violet and yellow. When heated (saponified) with alcoholic potash, the odor of guaiacol is developed.

It is incompatible with the alkalies, which split up benzosol into guaiacol and benzoic acid.

Actions and Uses.—Benzosol is decomposed slowly in the intestinal tract into guaiacol and benzoic acid which exert their usual actions. The liberated constituents are absorbed and excreted in the urine. It is claimed to be not irritating.

Its uses are analogous to those of creosote and of benzoic acid. It is said to be useful in incipient pulmonary tuberculosis, as an intestinal antiseptic in fermentation, diarrhea, typhoid fever, diabetes mellitus and as a urinary disinfectant in cystitis, etc. (See note under Beta-naphthol Benzoate.)

Dosage.—0.2 to 0.6 Gm. (3 to 10 grains), in powder, capsule, pill, or suspended in liquids or as an emulsion.

Manufactured by Farbwerke, vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York). U. S. patent No. 453,035 (expired).

GUAIACODEINE. — Codeine-Ortho-Guaiacol-Sulphonate. Guaiacodeine is Codeine-Ortho-Guaiacol-Sulphonate $C_{18}H_{21}NO_3C_6H_3(OH)(OCH_3)(HSO_3)1:2:6 = C_{25}H_{29}O_8NS$, the neutral codeine salt of guaiacol sulphonic acid.

Guaiacodeine is produced by the *double* decomposition of a soluble salt of codeine with the potassium or barium salts of ortho-guaiacol-sulphonic acid taken in molecular quantities.

It is a white crystalline powder Soluble in 90 parts of water, 450 parts of alcohol and 30 parts of methyl alcohol, insoluble in ether; very slightly soluble in chloroform. Very soluble in hot water.

A drop of solution of ferric chlorid added to a solution of the salt in water or alcohol produces a deep blue color, indicating the presence of ortho-guaiacol-sulphonic acid.

The salt melts between 163° C. and 165° C. (325.4 and 327.20 F.) to a white liquid. 0.1 Gm. dissolves in 10 Cc. concentrated sulphuric acid without color.

Theoretically the salt contains 59.44 per cent. anhydrous codein, or 63.20 U. S. P. codeine (containing 1 molecule of water of crystallization) and 40.56 per cent. ortho-guaiacol-sulphonic acid.

Ammonia and alkalies precipitate from a concentrated solution of the salt the alkaloid, codeine, which should respond to the tests of the U. S. P. for that alkaloid

Actions and Uses.—Those of Codeine. Since the proportion of guaiacol is small it cannot well be used to secure the action of this agent.

Manufactured by the New York Quinine and Chemical Works, New York.

U. S. patent No. 963,254 (July 5, 1910; expires 1927). Not trademarked.

GUAIACOL-SALOL—Guaiacolis Salicylas.—Salicylate of Guaiacol.—Guaiacol-salol is guaiacyl salicylate, $C_6H_4.OH.COO(.C_6H_4.OCH_3) = C_{14}H_{12}O_4$, the salicylic acid ester of guaiacol, closely related to phenyl salicylate (salol).

It is prepared by treating a mixture of sodium salicylate and sodium guaiacolate, in molecular proportions, with phosphorus oxychloride, washing the product of the reaction with water and crystallizing from alcohol.

It is a white crystalline powder, tasteless, but having a salol-like odor. It is insoluble in water, but soluble in alcohol, ether and chloroform. It melts at 65° C. (149° F.).

Being an ester, it is decomposed by alkalies and alkaline carbonates with the formation of alkali salicylate and alkali *guaiacol* and salicylic acid. The alcoholic solution is colored wine red by the addition of ferric chloride, but if the alcoholic solution be dropped into a watery solution of ferric chloride a turbidity but no coloration is produced.

Actions and Uses.—This compound acts like its constituents, being antiseptic and antirheumatic. It is said to be useful in phthisical diarrhea, dysentery, rheumatism, marasmus, chorea, etc. (See note under Beta-naphthol Benzoate.)

Dosage.—1 Gm. (15 grains).

Manufactured by Fabrik von Heyden, Radebeul, near Dresden, Germany (Merck & Co., New York).

GUAIAMAR — Guaiacolglycerylester.—Guaiamar is glyceryl guaiacolate, $C_6H_4.OCH_3.O(CH_2OH.CHOH.CH_2)$, $1:2 = C_{10}H_{14}O_4$, the monoguaiacol ester of glycerin.

It is prepared by the reaction of two molecules of sodium hydroxide, one of guaiacol and two of monochlorhydrin at from 140° to 150° C. (284° to 302° F.). When the alkaline reaction has disappeared, the mass is diluted with water which leaves the greater part of the glycerin ester undissolved. The portion dissolved in the water *solution may* be extracted from the latter by ether.

It is a white crystalline, non-hygroscopic powder, melting at 75° C. (167° F.) and having a bitter, aromatic taste. It is soluble in 20 parts of water at the ordinary temperature, but dissolves best in warm water; it is soluble in alcohol, chloroform, ether and glycerin. Its solutions are *neutral* to test paper. It is decomposed by soluble hydroxides and carbonates and by strong acids.

Actions and Uses.—Guaiamar liberates guaiacol, partly in the stomach and partly in the intestinal canal, it being split up by the gastric and intestinal contents, with the assimilation of one molecule of water, into guaiacol and glycerin. By this evolution of guaiacol it is believed to exert an antiseptic action in the intestinal canal. It is said not to interfere with the normal process of digestion, but, on the contrary, exerts a tonic action. (See note under Beta-naphthol Benzoate.)

It is intended to be used as a substitute for guaiacol in any cases where the latter is indicated. In the form of ointment it has been recommended in acute articular rheumatism.

Dosage.—0.3 to 1.3 Gm. (5 to 20 grains) in capsules or dissolved in warm water. Locally, in the form of 25 per cent. ointment with wool fat (lanolin), by itself, or combined with belladonna, zinc or mercurial ointment, etc.

Manufactured by Mallinckrodt Chemical Works, St. Louis. U. S. patent No. 599,123 (Feb. 15, 1898; expires 1915).

GUJASANOL — Diethylglycocoll-Guaiacol Hydrochloride.—Gujasanol, $C_6H_4(OCH_3)(CH_2N(C_2H_5)_2.COO).HCl = C_{13}H_{19}NO_3$ HCl, is the hydrochloride of diethylglycocoll-guaiacol.

It is prepared by the action of chloracetylchloride on guaiacol and decomposition of the product with diethylamine.

It forms small, colorless, prismatic crystals, melting at 183° to 184° C. (361.4° to 363.2° F.), having a slight odor of guaiacol and a bitter saline taste. It is soluble in its own weight of water and in 25 parts of alcohol, but *insoluble* in ether.

The solution in water should be clear, colorless, and give a white precipitate with silver nitrate. The oily base separates on the addition of an alkali hydroxide. When incinerated on platinum it leaves no residue.

It is incompatible with alkalies and their carbonates.

Actions and Uses.—It is antiseptic and anesthetic. It is readily absorbed and splits off guaiacol in the organism with facility. Its antiseptic power is said to be about equivalent to that of boric acid.

Gujasanol has been recommended for the treatment of tuberculosis, both internally and subcutaneously. It is also said to be useful as a deodorant and to have given good results in putrid cystitis.

Dosage.—1 to 3 Gm. (15 to 45 grains) in wafers; subcutaneously, 3 to 4 Gm. (45 to 60 grains) in 20 per cent. aqueous solution; locally it may be used in from 0.1 to 2 per cent. solutions.

Manufactured by Farbwerke, vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York). U. S. patent No. 624,772 (May 9, 1899; expires 1916).

MONOTAL—Guaiacolis Methylglycolas.—Monotal is guaiacyl methyl glycolate, $CH_2(O.CH_3).COO.(C_6H_4.OCH_3)=C_{10}H_{12}O_4$, the methyl-glycolic acid ester of guaiacol.

Monotal is prepared by the action of methoxacetyl chloride on guaiacol.

Monotal occurs as a limpid, colorless oil, of a faintly aromatic odor, easily soluble in alcohol, ether, benzol, and chloroform; difficultly soluble in water. It is soluble in about 6 parts of olive oil. It boils under 15 mm. pressure at about 156° C. (312.8° F.). It is split up into guaiacol and methylglycolic acid when treated with caustic alkalies.

Monotal is easily saponified by aqueous or alcoholic solutions of potassium hydroxide and then gives the reactions characteristic of guaiacol and methylglycolic acid. When incinerated on platinum foil it leaves no residue. Its watery solution is not rendered turbid by solution of silver nitrate. It has a specific gravity of 1.17 to 1.18 at 20° C.

Actions and Uses.—Monotal is said to give the systemic effects of guaiacol without having its caustic and poisonous properties. It is easily absorbed by the skin. (See note under Creosote Carbonate.)

It is said to be useful as an analgesic for various painful affections in phlebitis and in pulmonary tuberculosis.

Dosage.—2 to 4 Cc. (½ to 1 fluidram) rubbed in or painted over the affected area once or twice daily.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 822,339 (June 5, 1906; expires 1923). U. S. trademark No. 62,612.

STYRACOL—Guaiacolis Cinnamas.—Guaiacol Cinnamate.—Styracol is guaiacyl cinnamate, $C_6H_5CH{:}CH.COO(C_6H_4.OCH_3 = C_{16}H_{14}O_3$, the cinnamic acid ester of guaiacol.

It is prepared by allowing guaiacol and cinnamyl chloride in molecular proportions to react on each other for two hours at the ordinary temperature, then heating the mixture on the water bath for a short time and purifying the product of the reaction by several crystallizations from boiling alcohol.

It forms colorless, odorless and tasteless crystalline needles, melting at 130° C. (266° F.). It is insoluble in water, but easily soluble in alcohol, acetone, chloroform and benzine. It contains 55 per cent. of guaiacol, which is split off by the action of alkalies.

It is incompatible with alkalies.

Actions and Uses.—Styracol is claimed to be an intestinal antiseptic and to combine the antituberculous actions of guaiacol and cinnamic acid. It is said to liberate in the intestinal canal a larger proportion of its guaiacol (up to 85 per cent.) than other synthetic preparations of that substance.

It is said to be useful in the initial stage of phthisis, chronic enteritis and intestinal disturbances in general, catarrh of the bladder, etc. (See note under Beta-naphthol Benzoate.)

Dosage.—1 Gm. (15 grains) in powder or tablets.

Manufactured by Knoll & Co., Ludwigshafen a. Rh., Germany, and New York. German patent No. 62,176. U. S. trademark No. 42,487.

THIOCOL—Potassii Guaiacolsulphonas.—Potassium Guaiacol-Sulphonate.—Thiocol is potassium guaiacol sulphonate, $C_6H_3(OH)\ (OCH_3)\ (KSO_3)1{:}2{:}6 = C_7H_7O_5KS$, the potassium salt of ortho-guaiacol sulphonic acid.

It is prepared by sulphonating guaiacol at a temperature not exceeding 70° to 80° C. (158° to 17[illegible] sulphuric acid, converting the guaiacol [illegible] into the barium salt, and this by double [illegible] sium [illegible] sulphate into the p[illegible] or faintly alkaline,

It is a colorless, [illegible] odorless, and having a faint bitter, followed by a sweet taste.

It is readily soluble in water, slightly soluble in ordinary alcohol, but insoluble in absolute alcohol and in ether or oils.

Its aqueous solution is not precipitated by barium chloride; ferric chloride produces an intense violet-blue color, which disappears on the addition of ammonia, or of concentrated solution of alkali chlorides or sulphates.

Actions and Uses.—Thiocol is said to be non-irritating to the mucous membranes of the digestive tract, readily absorbed, and is claimed to promote appetite and improve nutrition.

It is claimed that it is useful in pulmonary tuberculosis, acute and chronic bronchitis, pneumonia, whooping cough, emphysema of the lungs, etc., as a means of lessening expectoration, diminishing night sweats and improving nutrition.

Dosage.—0.3 to 1.3 Gm. (5 to 20 grains), in solution with orange syrup or in tablets.

Manufactured by F. Hoffmann-LaRoche & Co., Basel, Switzerland (The Hoffmann-LaRoche Chemical Works, New York). U. S. patent No. 650.218 (May 22, 1900; expires 1917). U. S. trademark No. 78.327.

Syrup Thiocol Roche.—A syrup containing thiocol 10.5 Gm. in 100 Cc. (6 grains in a fluidram).

HEDONAL—Methylpropylcarbinol Urethane.—Pentan-2-Ol-urethane.—Hedonal is pentan-2-ol urethane, $CH_3.CH_2.CH_2.CH(CH_3)O.CO.NH_2 = C_6H_{13}O_2N$. It is a derivative of urethane differing from ethyl carbamate, U. S. P., in that the ethyl radicle has been replaced by the radicle of methyl-propylcarbinol (pentan-2-ol) $.CH_3.CH_2.CH_2.CHOH.CH_3$.

It is prepared by heating the secondary methylpropylcarbinol or pentan-2-ol, $CH_3.CH_2.CH_2.CHOH.CH_3$ with urea nitrate under pressure (U. S. patent No. 659,202), also by other methods (German patents Nos. 120,863, 120,864, 120,865).

It is a white, crystalline powder, having a faint aromatic odor and taste, melting at 74° C. (165.2° F.), and boiling at 215° C. (419° F.). It dissolves in 120 parts of water at 37° C. (98.6° F.), but is more soluble at higher temperatures and is readily soluble in alcohol, ether, chloroform and other organic solvents. It is readily volatilized with the vapors of water or alcohol, and when boiled with alkalies is split up into its constituents, methylpropylcarbinol, ammonia and carbon dioxide.

On boiling with dilute sodium hydroxide, ammonia is evolved and recognized by the odor and the usual reagents; if then an aqueous solution of iodine in potassium iodide is added, and the mixture allowed to cool, the odor of iodoform derived from the alcohol is distinctly manifested.

It is incompatible with alkalies, their carbonates and bicarbonates.

Actions and Uses.—Hedonal appears to have a greater hypnotic effect than ethyl carbamate. It is said to be followed by no after-effects and is oxidized in the body to urea and carbon dioxide. It is employed in insomnia due to mental overwork or nervous excitement occurring in the course of neurasthenia or hysteria. It is claimed to be particularly useful preliminary to anesthesia, a hypnotic dose being given and anesthesia effected with chloroform after the patient has been asleep for an hour.

Dosage.—1 to 2 Gm. (15 to 30 grains), administered dry, followed by a swallow of water, or in wafers or capsules.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 659,202 (Oct. 9, 1900; expires 1917); German patents Nos. 11,496, 120,863, 120,864, 120,865.

Hedonal Tablets, 8 grains.—Each tablet contains hedonal 0.52 Gm. (8 grains).

HEMABOLOIDS.—Hemaboloids is a liquid said to contain in each 100 Cc. iron, combined with proteins, equivalent to 0.40 Gm. elementary iron, proteins and nucleoproteins (nitrogen x 6.25) 4.0 Gm., bone marrow extract 5.0 Gm., nuclein 0.04 Gm., in a menstruum containing 17 per cent. alcohol by volume. It is claimed that 75 per cent. of the iron is in a stable organic combination with vegetable nucleoproteins and does not react with hematoxylin (see Organic Iron), while the remaining 25 per cent. is more loosely combined.

Actions and Uses.—Hemaboloids is claimed to act as a promptly absorbable and non-irritant form of food-iron. It is said not to constipate nor stain the teeth.

Dosage.—15 Cc. (½ fluidounce) after each meal. Children in proportion. Each average dose of 15 Cc. (½ fluidounce) contains iron 0.06 Gm. (0.92 grains), proteins and nucleoproteins 0.62 Gm. (9.6 grains), bone marrow extract 0.775 Gm. (12 grains), nuclein 0.006 Gm. (0.1 grain).

Manufactured by the Palisade Manufacturing Company, Yonkers, N. Y. U. S. trademark.

HEMOGLOBIN DERIVATIVES.

Hemoglobin is the coloring matter of the blood corpuscles and is the most important iron-containing compound of the body. It exists in venous blood as hemoglobin, sometimes called reduced hemoglobin, and in the lungs takes on oxygen in a loose chemical combination becoming oxyhemoglobin.

Hemoglobin is obtained from oxyhemoglobin by the action of various reducing agents.

When ingested it is decomposed in the stomach, being converted into a protein, globin, and into hematin, an acid nonalbuminous substance, containing the iron of hemoglobin. The same decomposition is produced by heating in solution to 70°, and by various chemical agents. It is doubtful whether hematin is absorbed into the blood from the gastrointestinal canal.

Various preparations of hemoglobin have been put on the market. These are of two classes. 1. Preparations consisting essentially of oxyhemoglobin usually sold under the name hemoglobin. 2. Preparations derived by the action of reducing agents on the blood, such as zinc, pyrogallol, etc. They consist of reduced hemoglobin, or of some modification of it.

CUPRO-HEMOL—Hæmolum Cupratum.—Cupro-hemol is hemol containing 2 per cent. of copper and 0.4 per cent. of iron in organic combination.

It is prepared by precipitating a solution of blood with a dilute neutral solution of a copper salt at a temperature not materially exceeding 0° C. (32° F.).

Actions and Uses.—Cupro-hemol is said to be useful in tuberculosis, scrofula, anemia, chlorosis, etc.

Dosage.—The maximum dose is 0.5 Gm. (8 grains).

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York). German patent No. 86,146.

HEMOGALLOL.—Hemogallol is an organic iron compound produced from blood by reduction of its hemoglobin by means of pyrogallol.

Fresh defibrinated blood suitably diluted with water is mixed with an equal volume of saturated solution of pyrogallol which causes the precipitation of a voluminous precipitate which is separated, washed with water to remove pyrogallol, and finally with alcohol.

It is a reddish-brown, almost tasteless powder, insoluble in water, alcohol, etc.

It does not show the spectroscopic absorption bands of hemoglobin between D and E.

Actions and Uses.—It is claimed that hemogallol acts as a preparation of organic iron (see Organic Iron).

It is claimed to be useful in anemia, chronic nephritis, and convalescence.

Dosage.—0.25 to 0.5 Gm. (4 to 8 grains), one-half hour before meals in powder with sugar or in tablets.

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York). U. S. patent No. 541,096 (June 18, 1895; expires 1912).

HEMOGLOBIN—Hæmoglobinum.—Hæmoglobin, Hæmatocrystallin. Hemoglobin is the red coloring matter of blood.

Hemoglobin is a brownish-red powder, soluble in water. It is decomposed by extremely small amounts of acids, coagulates at 64° C. (147.2° F.) and is dextro-rotatory. It does not give characteristic albumin or iron reactions until decomposed. A solution mixed with a little sodium chlorid, evaporated over sulphuric acid to a syrupy consistence, mixed with 15 times its volume of glacial acetic acid and heated on a water bath for several hours, yields on cooling flat rhombic crystals of haematin hydrochloride with a dark violet-red color and metallic luster.

Action and Uses.—See organic iron. It is converted into hematin in the stomach.

Dosage.—0.3 to 2 Gm. (5 to 30 grains).

HEMOL—Hæmolum.—Reduced Hemoglobin—Parahemoglobulin—Hemoglobin Deoxidized by Zinc, Merck.—Hemol is an organic iron compound produced from blood by reduction, said to contain about 3 per cent. of iron in organic combination.

Neutralized blood is shaken with zinc dust and water, and the zinc removed from the product of the reduction (Zinc parahemoglobulin).

Hemol is a dark-brown, almost tasteless powder, insoluble in water, alcohol, etc. It contains traces of zinc oxide. The amount of iron may be determined by the method described in Merck's Prüfungsvorschriften für die pharmazeutischen Spezial-Präparate.

Actions and Uses.—It is claimed to have the action of an organic iron compound.

Hemol is claimed to be useful in anemia, chlorosis, etc.

Dosage.—0.12 to 0.5 Gm. (2 to 8 grains) in powder with sugar or in wafers.

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York). U. S. patent No. 541,033 (July 2, 1895; expires 1912).

HEXAMETHYLENAMINE AND HEXAMETHYLENAMINE COMPOUNDS

Hexamethylenamine is official in the United States Pharmacopeia. For description see the pharmacopeia, or the Physician's Manual of the United States Pharmacopeia and National Formulary.

AMINOFORM.—A name applied to Hexamethylenamina, U. S. P.

Sold by C. Bischoff & Co., New York.

FORMIN.—A name applied to Hexamethylenamina, U. S. P.

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York).

UROTROPINE.—A name applied to Hexamethylenamina, U. S. P.

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin, Germany (Schering & Glatz, New York). U. S. trademark No. 58,394.

HEXAMETHYLENAMINE METHYLENCITRATE—*Hexamethylenaminæ Methylencitras.*—Hexamethylenamine methylencitrate, $C_6H_8O_7(CH_2)_6N_4 = C_{12}H_{20}O_7N_4$, is a compound of hexamethylenamine with anhydromethylencitric acid.

It is a white, crystalline powder, melting with decomposition at 165° to 175° C. (329° to 347° F.), having an agreeable, acidulous taste and acid reaction. It is soluble in about 10 parts of water, but almost insoluble in alcohol and ether. By dilute acids and more easily by alkalies it is decomposed with the liberation of formaldehyde. On addition of 1 per cent. solution of phloroglucin to a solution of hexamethylenamine methylencitrate, followed by sodium hydroxide, the intense rose-red color characteristic of the liberated formaldehyde is developed.

It is incompatible with acids and alkalies.

Actions and Uses.—It is a urinary antiseptic and germicide claimed to be more prompt and energetic in its action than hexamethylenamine, acting equally well whether the urine be alkaline or acid in reaction, rapidly clearing it up and allaying pain.

It is said to be useful in cystitis, pyelitis, prostatic diseases and urethritis. It is also said to be an efficient urinary antiseptic in infectious diseases in which bacteria are present in the urine.

It may be used as a phophylactic against infection in case of operations or instrumental manipulation of the genitourinary tract.

Dosage.—0.6 to 1 Gm. (10 to 15 grains).

Proprietary Preparation.

HELMITOL.—A name applied to Hexamethylenamine Methylencitrate.

Manufactured by Farbenfabriken, vorm. Friedr, Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 722,275 (March 10, 1903; expires 1920). U. S. trademark No. 39,580.

Helmitol Tablets, 5 grains. Each tablet contains helmitol 0.3 Gm. (5 grains).

SALIFORMIN—Hexamethylenaminæ Salicylas, Merck.—Hexamethylenamine salicylate, Merck.—Saliformin is hexamethylenamine salicylate, $(CH_2)_6N_4C_6H_4.OH.COOH$, a weak salt of hexamethylenamine and salicylic acid.

It is prepared by dissolving equal weights of hexamethylenamine and salicylic acid in water and evaporating the solution to dryness at a temperature below 60° C. (140° F.).

It is a white, crystalline powder, having an acidulous and disagreeable taste, readily soluble in water or alcohol.

It is soluble in cold sulphuric acid without color, becoming crimson on heating. Its aqueous solution is colored deep green by copper sulphate, violet by ferric chloride, and forms a yellow precipitate with bromine.

It is decomposed by basic substances (soluble hydroxides, carbonates, etc.) and by strong acids. It is incompatible with salts of iron and other metals which form insoluble compounds with salicylates.

Actions and Uses.—Saliformin is recommended as a genitourinary antiseptic and uric-acid solvent. Its action does not differ materially from that of a mixture of hexamethylenamine and salicylic acid, for it is largely hydrolysed into its constituents in the presence of water.

IODOFORMOGEN — Iodoformalbumen. —Iodoformogen is a nearly odorless mixture of iodoform and albumin.

It is prepared by precipitating a solution of albumin with alcoholic solution of iodoform and heating the precipitate at 120° C. (248° F.).

It is a very fine, voluminous, light-yellow, nearly odorless powder, non-hygroscopic and non-conglutinating. It is insoluble in water, and sterilizable at 100° C. (212° F.) without decomposition or change. It contains about 12 per cent. iodine.

Actions and Uses.—Its action is that of iodoform, which is slowly liberated when it is in contact with wound surfaces, making the action more persistent. It limits secretion, favors granulation and promotes drying.

Iodoformogen is recommended by the manufacturer as a dusting powder for ulcerated surfaces.

Dosage.—Being about three times as voluminous as iodoform, it is usually applied undiluted to the affected parts. It may be used as a snuff in ozena, mixed with an equal amount of boric acid.

Manufactured by Knoll & Co., Ludwigshafen a. Rh., Germany and New York. German patent No. 95,580. *U. S. trademark* No. 31,186.

IODO-MANGAN — Liquor Ferro-Mangani Iodopeptonati "Dieterich."—Iodo-mangan is Ferromangan Dieterich with the addition of 1 per cent. of iodopeptone.[1] Iodopeptone contains 15 per cent. of iodine.

The process of preparation is the same as that given under Ferro-Mangan "Dieterich," with the addition of a solution of iodopeptone.

Iodo-mangan is a clear dark-brown liquid of agreeable odor and taste, and a slight acid reaction.

Method of Valuation: After determination of the percentage of iron and manganese a test method should be employed, as described by Dr. Karl Dieterich in Helfenberg Annals, 1901, pages 162-165, to ascertain the percentage of halogens in Iodopeptone: About 0.5 iodopeptone should be thoroughly mixed with a few grams of a mixture of 1 part potassium nitrate and 2 parts sodium carbonate either in a porcelain or platinum crucible. The mixture is then covered with a light layer of sodium carbonate, covered and carefully heated until reaction sets in. When finished a little potassium nitrate is added to obtain a smooth flux, then the molten mass is exposed to glowheat for about 15 minutes. After cooling it is dissolved in hot water, rinsed into a beaker, filtered if necessary, acidulated dith diluted acetic acid and any iodate reduced with sulphurous acid. The excess of acid is driven off by heat, the liquid strongly acidulated with nitric acid, again heated, until the gas formation ceases, then precipitated while hot with silver nitrate. The silver iodide is collected on a weighed filter, washed with very dilute ammonia water, as the preparation contains hydrochloric acid, dried and weighed.

Actions and Uses.—It is claimed to be a reconstructive tonic and blood making adjuvant, with favorable action in affections of the glandular system.

Iodo-mangan is said to be useful in scrofulosis, rheumatism, etc.

Dosage.—4 to 16 Cc. (1 to 4 fluidrams), according to age, three times a day.

Manufactured by Chemische Fabrik Helfenberg A. G., near Dresden, Germany. (Reinschild Chemical Co., New York.) No patents. U. S. trademark No. 57,870.

IODONE.—Iodonum—Iodone $(C_6H_4C_2O_2)_2 KI.I_4$, is a periodide of phthalic acid anhydride.

Iodone is prepared by treating a solution of phthalic-acid anhydride in acetic ether, with a solution of iodine and potassium iodide, and crystallizing the product from suitable solvents.

Iodone occurs in the form of dark green prismatic crystals which melt with decomposition at 163° C. (325.4° F.). When freshly prepared it is odorless, but on standing, traces of iodine are liberated, giving it a faint odor of iodine. It is gradually decomposed into phthalic acid, iodine, and potassium iodide by water, in which the decomposition products dissolve until a saturated iodine potassium iodide solution results. Any excess of iodine remaining in contact with the supernatant liquid remains unchanged. Alcohol, chloroform, and ether decompose iodone, but more slowly than water. Iodone crystals are stable in dry air; exposed to damp air, they gradually liberate iodine.

When 0.1 Gm. iodone is heated in a crucible at not more than a dull red heat, the compound chars, iodine vapor is driven off, and a residue of white potassium iodide remains. At a bright red heat the latter is dissipated, leaving no weighable residue (absence of metallic impurities).

About 0.1 Gm. iodone, accurately weighed, is allowed to react, with occasional agitation, with a solution of 1 Gm. potassium iodid in 50 c.c. water. At the end of 15-20 minutes the titration of this solution with tenth-normal thiosulphate solution should indicate the presence of not less than 51.1 per cent. iodine.

Iodone surgical dressing and dusting powder, assayed by the above process, should yield not less than 2 per cent. of available iodine. (About 2.5 Gm. should be taken for the assay.)

Actions and Uses.—Like iodine, iodone is a potent germicide and stimulant to the processes of repair in wounds. It is said to be useful in all conditions in which the local use of iodine is indicated.

Dosage.—Iodone is not used in substance but the employment of its preparations should be regulated on the basis of their iodine content.

Manufactured by the Henry C. Blair Co., Philadelphia, Pa. U. S. patent applied for. Not trademarked.

Iodone Oil—Oleum Iodoni.—Iodone oil is a 2 per cent. solution of iodone crystals in a mixture of alcohol, castor oil, and cotton seed oil. It is said to yield about 1 per cent. of iodine, slowly liberated on prolonged contact with moisture and to contain about 20 per cent. alcohol.

Iodone oil is prepared by dissolving iodone crystals in a mixture of alcohol and oils to which sufficient iodine has been added to overcome the decomposing effects of the solvent on iodone.

It is a clear dark reddish-brown oily liquid, having a specific gravity of about 0.912 at 25° C. (78° F.) and a faint alcohol-like odor.

When shaken with chloroform and water the chloroform acquires a violet color, which is decolorized by shaking with a solution of sodium thiosulphate.

If 5 Cc. of the oil is dissolved in 15 Cc. of chloroform and treated as under iodone ointment, considerable time being allowed during the titration for the complete liberation of the iodine (at least twenty-four hours), about 1 per cent. iodine, calculated from the volume of volumetric sodium thiosulphate solution, should be indicated.

Actions and Uses.—Iodone oil has the germicidal and alterative actions due to the iodine which is liberated on contact with moisture.

It is said to be useful in all catarrhal affections of mucous membranes, hay fever, etc.

Dosage.—Its employment should be regulated on the basis of its liberating 1 per cent. of iodine on contact with moisture. It may be applied as a spray or on pledgets of cotton or tampons. It can be injected hypodermically into tuberculous joints, etc.

Iodone Ointment—Unguentum Iodoni.—Iodone ointment is a mixture of iodone crystals with petrolatum, said to contain about 4 per cent. of iodine and to yield about 2 per cent. of available iodine slowly liberated on contact with moisture.

Iodone ointment is a dark green unctuous mass, having the consistency of petrolatum and a faint iodine-like odor.

A small amount dissolved in chloroform in a test tube and shaken with water should impart to the chloroform a violet color, which is destroyed by addition of sodium thiosulphate solution.

If 2 to 3 Gm. of iodone ointment be weighed and dissolved in 15 Cc. of chloroform and 30 Cc. of water added, the mixture shaken frequently during one hour, and titrated with tenth normal sodium thiosulphate solution using starch as indicator, not less than 2 per cent. of iodine should be indicated.

Actions and Uses.—Iodone ointment has germicidal, alterative and stimulant powers due to the iodine liberated.

It is said to be useful in all conditions in which the local use of iodine in ointment is indicated.

Dosage.—Its employment should be regulated on the basis of the liberation of 2 per cent. of available iodine on contact with moisture.

Iodone Surgical Dressing and Dusting Powder—Pulvis Iodoni Compositus.—Iodone surgical dressing and dusting powder is a mixture of four parts of iodone and 96 parts pure sterile talcum.

Dosage.—Its employment as a surgical dressing and dusting powder should be regulated on the basis of its containing 2 per cent. of available iodine, slowly liberated on contact with the moisture of wound secretions, etc.

IOTHION — Di-Iodo-Hydroxy-Propane. — Iothion is 1,3-di-iodo-propane-2-ol $CH_2I.CHOH.CH_2I = C_3H_6OI_2$.

Dichlorhydrin, obtained by chlorinating glycerin, is heated with the theoretical quantity of potassium iodide in the presence of water, chlorine being replaced by iodine with the production of di-iodo-hydroxy-propane.

Iothion is a yellowish, oily, heavy liquid, of sp. gr. 2.4 to 2.5, containing 77 per cent. of iodine. It is volatile at the body temperatu [illegible] unpleasantly odorous. It is insoluble in water but so [illegible] alcohol and other organic solvents. It is [illegible] weak alkalies.

If Iothion be heated on the water bath under a reflux condenser for 5 to 6 hours, with 33 per cent. solution of potassium hydroxide and the iodine liberated from the residue by sulphuric acid and sodium nitrite and extracted with carbon disulphide, the titration of this iodine carbon disulphide solution with sodium thiosulphate in the usual way, should indicate 77 per cent. of iodine.

Actions and Uses.—Iothion acts like iodine and the iodides, but it is said to be rapidly absorbed by the intact skin.

It is said to be a satisfactory substitute for iodine and iodides. It is applied to the surface of the body in the same manner as mercurial inunctions.

Dosage.—It is applied in the form of a 25 to 50 per cent. ointment with a mixture of equal parts of wool fat (lanolin) and petrolatum as a base.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. trademark No. 39,252.

KEFIR FUNGI—Kefir fungi is a mixture of bacteria and yeasts capable of causing lactic acid fermentation of milk.

Kefir occurs in the form of white irregular roundish bodies, of the size of a walnut, with a very rough, furrowed surface, and of a tough gelatinous consistency. The substance contains Saccharomyces cerevisiæ (Heyden), Bacillus acidi lactici (Pasteur),

---

[1] Iodomangan formerly contained 0.45 per cent. of iodopeptone.

Dispora Caucasica (Kern). It acts on milk as follows: Fat, salt and water of the milk remain unaffected. The lactose is gradually decreased and the lactic acid increased. Alcohol is produced along with carbon dioxide. 10 per cent. of the casein is converted into acid albumin and peptones, 10 per cent. into hemialbumose and the rest loses its lime. (U. S. Disp., 19th ed., p. 1540.)

Action and Uses.—Kefir fungi are used for the preparation of fermented milk which contains lactic acid, alcohol, the fats, salt and water of the milk. Kefir milk acts as an easily digestible food in many cases of dyspepsia and lack of digestive power. It is also serviceable in some cases in the prevention of intestinal putrefaction.

Dosage.—Kefir kumyss may be prepared by adding active kefir grains to fresh cows' milk, kept at a temperature of 21°-27° C. (70° to 80° F.) until the effect of fermentation becomes apparent by the rising of the grains to the surface. The grains may then be strained off, and the milk, which now contains sufficient yeast-cells to insure continuance of the fermentation, left to itself in well-corked bottles.

KERATIN—Keratinum.—Keratin is a proteid substance which forms the chief part of horns, hoofs, feathers, wool, etc.

To prepare keratin horn shavings are macerated for some days in a mixture of equal parts of ether and alcohol; decanting the liquid and washing the residue with warm water. The washed shavings are then treated with an acid solution of pepsin at 40° C. (104° F.). After further washing with water the residue is dried and powdered.

Keratin occurs as a brownish yellow powder or in transparent white or grayish white scales, tasteless and odorless. It is soluble in concentrated acetic acid, caustic alkalies and ammonia, but insoluble in water, alcohol, ether, dilute acetic acid or acid pepsin solutions. It is decomposed by long boiling under pressure forming a turbid solution with the liberation of hydrogen sulphide. Boiling with dilute sulphuric acid converts it to leucine, tyrosine and other products. On ignition it emits the odor of burning feathers and the remaining carbon is very difficultly burned. On complete combustion the ash should not exceed 1 per cent. 24 hours' digestion with 15 times its volume of ammonia or glacial acetic acid solution at 25°-40° C. (77°-104° F.) should not leave more than 0.3 per cent. insoluble matter.

Uses.—For coating pills to pass the stomach unchanged.

LACTOPHENIN — Lactopheninum. — Phenetidinum lactylatum (Pharm. Helvetica. edit. 4)—Lactylparaphenetidin.—Lactophenin is lactylparaphenetidin. $C_6H_4.OC_2H_5.NH(CH_3.CHOH.CO{=}C_{11}H_{15}NO_3$. a phenetidin derivative differing from acetphenetidine (Phenacetin) in that the acetic-acid radicle of acetphenetidine is replaced by the lactic-acid radicle (lactyl).

It is prepared by heating lactic acid and paraphenetidin. in molecular proportions, at 180° C. (356° F.) until all the liberated water is expelled and crystallizing the product from hot water

Lactophenin occurs as a white, crystalline, odorless powder, of slightly bitter taste and neutral reaction. It melts at 117.5° to 118° C. (243.5° to 244.4° F.). It is rather difficultly soluble in cold water (1:330), and is soluble in 55 parts of boiling water. It is soluble in 8.5 parts of alcohol, and is not precipitated from this solution by water. In ether and petroleum it is difficultly soluble.

On boiling 0.2 Gm. of lactophenin with 2 Cc. hydrochloric acid for one minute, then diluting the solution with 20 Cc. water, and filtering when cold, the filtrate will become colored a ruby red on the addition of chromic acid solution.

On dissolving 0.1 Gm. lactophenin in 10 Cc. hot water, and filtering when cold, the filtrate, on the addition of bromin water, should afford a decided turbidity which disappears on the addition of much water.

The aqueous solution of lactophenin must not have an acid reaction.

No blue coloration should develop on adding potassium dichromate solution to the cold aqueous solution of lactophenin (absence of phenetidin salts).

Lactophenin should dissolve in concentrated sulphuric acid in the cold without coloration (absence of foreign organic mixtures), and on incineration should leave no weighable residue (absence of inorganic admixtures).

Actions and Uses.—Lactophenin is an antipyretic and analgesic similar to acetphenetidin (phenacetin). It is claimed that it has a more marked action as a hypnotic than acetphenetidin (phenacetin) and that at the same time respiration and circulation remain unchanged. It is also claimed that the lactic acid constituent is more easily separated from the compound than is the case with the acetic acid radicle of acetphenetidin. It is stated that the preparation is absorbed from the stomach to a large extent, so that the activity of the doses given reaches its maximum in a short time.

The therapeutic indications of lactophenin are similar to those of acetphenetidin (phenacetin). It is claimed by the manufacturers to be particularly valuable in the treatment of typhoid fever on account of its combined antipyretic and sedative properties. On the other hand, it is the general opinion that antipyretics should not be used in the treatment of typhoid fever unless under very exceptional circumstances. In the opinion of good authorities the action and uses of lactophenin do not materially differ from those of acetphenetidin (phenacetin).

Dosage.—The initial dose is 0.5 Gm. (8 grains) for adults and the maximum daily dose 3 to 5 Gm. (45 to 75 grains).

Manufactured by C. F. Boehringer & Soehne, Waldhof near Mannheim, Germany (Merck & Co., New York). U. S. patent No. 503,743 (expired). U. S. trademark No. 24,643.

LECITHIN PREPARATIONS

LECITHIN.—Lecithin consists of the esters of oleic, stearic, palmitic or other fatty acid with glycerophosphoric acid combined with cholin; occurring in combination with proteids in many animal and vegetable tissues, especially in nervous matter and egg-yolk.

Lecithin is best prepared from egg-yolk (in which it exists as vitellin) by dissolving out the lecithin by strong alcohol.

It is a yellowish-brown, waxy solid of peculiar odor, soluble in an equal volume of cold absolute alcohol, readily soluble in chloroform, petroleum, benzin, and fats, less readily in ether. It is insoluble in water, but swells, giving the peculiar "myeline forms," and decomposes on prolonged contact. It is hygroscopic on exposure to air.

The alcoholic solution is precipitated by platinum or cadmium chloride. It is decomposed by alkalies with the formation of cholin and trimethylamine. The ash contains phosphoric acid. The different lecithins contain from 3.84 to 4.12 per cent, of phosphorus and 1.73 to 1.86 per cent. of nitrogen. The ratio of nitrogen to phosphorus should be as 1 to 2.21.

Lecithin is incompatible with alkalies; it should be kept in well-stoppered bottles and should be protected from the light.

Actions and Uses.—Lecithin is supposed to act as a stimulant to nutrition and not as a direct nutrient, and to increase the number of the red blood corpuscles and the amount of hemoglobin. Some investigators state that there is a slight increase in the proportion of large mononuclear leukocytes, that the appetite is improved, that there is a retention of nitrogen and a diminution in the excretion of phosphoric and sulphuric acids, indicating a storage of proteids, and that uric acid is perhaps slightly diminished. Lecithin, even in large doses, is not toxic. (See note under Creosote Carbonate.)

The ordinary diet contains from 5 to 15 Gm. (75 to 225 grains), and some observers claim that the benefits of the administration of lecithin can be obtained by an increased use of lecithin-containing food (eggs, etc.), but others claim that the raw or combined lecithin is ineffective.

Dosage.—It may be given by mouth in doses of 0.1 to 0.5 Gm. (1.5 to 8 grains) per day, in pill form, before meals, or, hypodermically 1 Cc. (15 minims) of a 5 per cent. solution in oil. daily. Infants, one-third of these doses.

GLYCEROLE OF LECITHIN—Glyceritum Lecithini.—Glycerole of lecithin is a solution of lecithin in pure glycerin, containing in each 100 Cc., 1.6 Gm. of pure lecithin.

Actions and Uses.—See Lecithin.

Dosage.—4 Cc. (1 fluidram) containing 0.06 Gm. (1 grain) of lecithin.

Manufactured by Fairchild Bros. & Foster, New York. Not patented or trademarked.

LECIBRIN.—Lecibrin is lecithin from the brain in combination with nucleoproteins, containing 33⅓ per cent. by weight of lecithin.

Lecibrin is put up in gelatin coated "pepules," each containing 0.2 Gm. (3 grains), the equivalent of 0.0027 Gm. (1/25 grain) of elementary phosphorus.

Actions and Uses.—See Lecithin. Said to be better borne than lecithin in some cases.

Dosage.—One to three pepules.

Manufactured by Fairchild Bros. & Foster, New York. U. S. trademark No. 50,967.

LECITHIN SOLUTION.—A solution of lecithin containing 1.6 Gm. of lecithin in 100 Cc. of a glycerin-alcoholic menstruum containing 18.5 per cent. of alcohol by volume.

Actions and Uses.—See Lecithin.

Dosage.—4 Cc. (1 fluidram), containing 0.06 Gm. (1 grain) of lecithin.

Manufactured by Fairchild Bros. & Foster, New York. Not patented or trademarked.

LECITHOL.—An emulsion-like solution of lecithin containing 18 per cent. of absolute alcohol by volume, and .06 Gm. (1 grain) of lecithin per 4 Cc. (1 fluidram).

The lecithin is separated from hogs' brains.

An opalescent yellow liquid of pleasant taste and odor.

Test: From lecithol, 10 Cc., the alcohol is removed by evaporating on the water-bath; then water, 90 Cc., is added. Next concentrated hydrochloric acid, 2 Cc. is added, and then, with thorough shaking, gradually 2 Cc. chloroform. The liquid precipitate which separates out, containing nearly all the lecithin, is collected and treated with strong sulphuric acid and fuming nitric acid. After all the organic matter is decomposed, the phosphorus is determined in the usual way. From this the percentage of lecithin is calculated.

Actions and Uses.—See Lecithin.

Dosage.—4 to 8 Cc. (1 to 2 fluidrams) immediately before or after meals.

Manufactured by Armour & Co., Chicago.

NEURO-LECITHIN-Abbott. — Neuro-lecithin-Abbott is a preparation of lecithin with small amounts of fats and cholesterin, the amount of lecithin being determined by assay.

Neuro-lecithin is said to be made from the brain and spinal cord of animals. The water and fat are separated by heat; the soluble portions are extracted from the residue with ether; this is precipitated with acetone.

For properties and tests see Lecithin. The amount of lecithin is determined by a quantitative estimation of phosphorus and nitrogen. The material is exhausted with ether-alcohol at the boiling point of the mixture, the solution evaporated, the residue fused with sodium carbonate and potassium nitrate and phosphorus determined in the fusion. The amount of phosphorus found multiplied by 26 (806/31) is taken to indicate the amount of lecithin.

Actions, Uses and Dosage.—See Lecithin.

Manufactured by the Abbott Alkaloidal Co., Chicago. U. S. trademark No. 65,384.

Neuro-Lecithin Tablets-Abbott.—Each tablet contains neuro-lecithin 0.03 Gm. (½ grain).

Neuro-Lecithin Pills-Abbott.—Each pill contains neuro-lecithin 0.03 Gm. (½ grain).

LENIGALLOL—Pyrogallol Triacetas. — Triacetylpyrogallol. Lenigallol is pyrogallol triacetate, $C_6H_3(CH_3CO_2)_3 = C_{12}H_{12}O_6$, obtained by replacing the hydroxyl groups of pyrogallol with acetyl groups.

It is prepared by boiling 10 parts of pyrogallol, 1 part of sodium acetate, and 25 parts of acetic anhydride for 2 hours, and washing the crystalline product on a filter with water.

It is a white, crystalline powder, melting at 165° C. (329° F.). It is insoluble in water, but soluble with decomposition in warm aqueous alkalies.

It is incompatible with alkalies, strong acids and oxidizing agents

Actions and Uses.—Lenigallol is said to be non-poisonous and non-irritating, but a mild and painless corrosive. (See note under Creosote Carbonate.)

It is introduced as a substitute for pyrogallol in psoriasis, lupus, acute and subacute eczema of children and other skin diseases.

Dosage.—In 5 to 10 per cent. ointment with zinc oxide.

Manufactured by Knoll & Co., Ludwigshafen a. Rh., Germany. German patent No. 105,240.

LYSIDIN.—Lysidin is a 50 per cent. solution of ethylene-ethenyl-amidine,  $\begin{matrix} CH_2.N \diagdown \\ | \qquad\quad C.CH_3 \\ CH_2.NH \diagup \end{matrix} = C_4H_8N_2$, a monatomic base derived from ethylene diamine.

It is prepared by subjecting ethylenediamine hydrochloride and sodium acetate to dry distillation, decomposing the hydrochloride of the new base with concentrated potassium hydroxide and crystallizing.

It forms small, colorless, very hygroscopic needles, melting at 105° to 106° C. (221° to 222.8° F.). It is very soluble in water and in alcohol forming alkaline solutions; it is also soluble in chloroform, but insoluble in ether. It forms a very soluble salt with uric acid.

It should form a clear and colorless solution and give the usual alkaloidal reactions.

Being a strong base it is incompatible with acids and with the salts of many metals and of the alkaloids, which it decomposes.

Actions and Uses.—Lysidin is said to be a diuretic and is recommended as a uric acid solvent on the theory that, because it forms a very soluble salt with uric acid, it will facilitate the elimination of that substance. It is claimed that it is superior to piperazine.

It is said to be useful in gout, lithiasis and the various forms of the so-called uric acid diathesis.

Manufactured by Farbwerke, vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York).

MASSOLIN—Cultura Bacilli Bulgarici-Lederle.—Massolin is a pure culture of the *Bacillus bulgaricus* of Massol, grown on *one of the following media:* Calcium carbonate lactose broth, calcium carbonate dextrose broth, calcium carbonate Cohendy broth, or Cohendy broth.

The material for one of the above broths is sterilized for thirty minutes on three successive days and then placed in the incubator for at least forty-eight hours to determine its sterility before using. The material is then put into large flasks, inoculated from test tube cultures of the bacillus and incubated at 37° C. (98.5° F.) for from twenty-four to ninety-six hours. It is then tested to see that it is free from contaminating organisms.

The preparation is of an amber color and has the odor and taste of the particular medium employed as its base.

The material should be inoculated into milk and into the above media in test tubes and smeared on Cohendy agar. The cultures should be examined microscopically for the detection of contaminating organisms.

Actions and Uses.—The culture tends to prevent the growth of putrefactive and pathogenic organisms. It is said to be useful in the treatment of suppurative conditions and is said to have been found especially beneficial in atrophic rhinitis, chronic nasal catarrh, inflammations of the frontal sinus, antrum, ethmoidal cells, middle ear, etc.

Dosage.—The culture should be liberally applied directly to the diseased area and in ordinary nose and throat affections the contents of one bottle, 7.5 Gm. (¼ ounce) may be employed at each treatment.

Manufactured by Lederle Antitoxin Laboratories, New York (Schieffelin & Co., New York).

No patent or trademark. U. S. Government License No. 17.

MEDICINAL FOODS

The so-called "Liquid Foods," "Medicinal Foods" or "Predigested Foods," as found on the market, are solutions containing as the essential constituents small amounts of protein substances and carbohydrates, preserved by alcohol.

The protein substances should be rendered soluble, i. e., converted to peptones and proteoses, by means of enzymes. While the hydrolysis of proteids to soluble proteoses may also be effected by means of acids or superheated steam, these products should be excluded from medicinal foods because of the uncertainty as to their composition and behavior—being held toxic and dangerous by some. The protein content of these liquid medicinal foods (obtained by multiplying the total nitrogen content by 6.25) ranges from 0.5 to more than 6 per cent. The carbohydrates present in these foods are sucrose (cane sugar), maltose, glucose, invert sugar, dextrin and possibly also lactose (milk sugar). In these foods, as found on the market, the quantity of carbohydrates ranges from 0.55 to more than 15 per cent. The alcohol content varies from 12.0 to 19 per cent. of absolute alcohol by weight. Some contain large amounts of glycerin.

Actions and Uses.—The value of medicinal foods depends on the proteins and carbohydrates contained therein. Glycerin does not, so far as known at present, possess any recognized food value, although there are a number of experiments on record to indicate that it influences metabolism. While the value of alcohol in the treatment of disease is fully appreciated, its value as a food product, pure and simple, in disease is an open question. It probably acts as a saver of fat and carbohydrate, but not as a tissue builder. The nutritive value of these medicinal foods, therefore, should be considered as based on their carbohydrate and protein content, exclusive of alcohol or glycerin. The calculated food value of a considerable number of medicinal foods, on the basis of the potential energy (calorific value) due to proteins and carbohydrates shows that some possess but one-sixth the value of milk, while the best have a trifle greater calorific value. The Council has decided that no liquid medicinal or predigested food be given consideration which contains less nutritive value, exclusive of alcohol and glycerin, than milk; and at least one-fourth of this should reside in nitrogenous constituents.

Dosage.—None of the commercial liquid medicinal or predigested foods contains sufficient food material to maintain normal nutrition. A man doing moderate work requires an amount of food which furnishes energy to 3,000 calories per day, and while, in sickness, this amount is not required, it should not fall much below 1,500 calories per twenty-four hours. The examination of commercial liquid food shows that the average daily dose recommended supplies from 10 to 111 calories based on protein and carbohydrate. To sustain the vitality of a patient during a serious illness, 2,000 Cc. of milk, giving about 1,430 calories, are required; to supply the same number of calories, even if the alcohol is considered to have direct food value, from 700 to 1,500 Cc. of the medicinal foods will be required. In many cases the amount of alcohol exhibited by these quantities would keep the patient in an alcoholic stupor continually. It should, therefore, be remembered that the patient is receiving a starvation diet when these preparations are given in ordinary doses. Unless the daily dose advised contains at least 100 calories, exclusive of alcohol and glycerol, a preparation should not be depended on as of noteworthy importance in helping to sustain life even for a very limited period.

DEXTROSE.—Saccharum Amylaceum.

Dextrose, $C_6H_{12}O_6 + H_2O$, is a carbohydrate prepared by the action of dilute acids on starch; it also occurs naturally.

Dextrose containing a molecule of water of crystallization occurs in white crystalline masses. It is soluble in its own weight of water at 15° C. (59° F.); in 50 parts alcohol (85 per cent.) at 17° C. (62.6° F.) and in 11 parts at the boiling temperature.

An aqueous solution (1-10) of dextrose should yield after the addition of dilute nitric acid not more than a slight turbidity with either barium nitrate or silver nitrate; and after the addition of ammonia should produce no precipitate with ammonium oxalate.

An aqueous solution (1-20) of dextrose should not change when heated with hydrogen sulphide.

Actions and Uses.—Dextrose is quite readily digested and may be used in place of cane sugar as a food.

Dosage.—180 Gms. (6 oz.) daily.

DRY PEPTONOIDS.—Dry peptonoids is stated to contain 40 per cent. of proteins and 53 per cent. of carbohydrates.

It is said to be made from beef, milk and wheat, by digesting the protein with pepsin and pancreatin and the carbohydrates with pancreatin and malt diastase. The resultant solutions are assayed, mixed in proper proportions and, the acid used in the digestion having been neutralized, concentrated *in vacuo*, sterilized, dried and brought to uniform composition by the addition of milk sugar.

It consists of light brown granules of pleasant odor and taste and is very soluble in water and other fluid media.

Actions and Uses.—See Medicinal Foods. The nutritive value of 500 Gm. of Dry Peptonoids corresponds to approximately 2,000 calories, of which 870 are due to protein and 1,130 to carbohydrates and fat. The largest dose usually given (16 Gm.) equals, therefore, almost 64 calories. It is claimed to be especially useful for nutrient enemata.

Dosage.—For an adult 8 to 16 Gm. (¼ to ½ ounce), taken in water, milk, wine, broths, soups, etc., also in gruels, in which case it should first be dissolved in a small quantity of water.

Manufactured by the Arlington Chemical Co., Yonkers, N. Y. U. S. trademark. Oct. 17, 1882.

LIQUID PEPTONOIDS.—Liquid peptonoids contain 4.5 to 5 per cent. nitrogenous matter (nitrogen x 6.25), 10.6 to 11.5 per cent. carbohydrates (glucose, lactose and sucrose) and 17.5 to 17.8 per cent. alcohol by volume (14 to 14.1 by weight).

It is said to be made from beef, milk and wheat by digesting the protein with pepsin and pancreatin and the carbohydrates with pancreatin and malt diastase.

It is a light brown fluid of aromatic taste and odor and acid in reaction. Its specific gravity is 1.047 to 1.049.

Actions and Uses.—See Medicinal Foods. The nutritive value of 500 Gm. of Liquid Peptonoids corresponds to 335 to 345.1 calories, of which 108.7 to 118.3 are due to protein and 216.7 to 236.4 to carbohydrates. The same quantity of milk represents 360 calories, of which 84 are due to protein and 98.4 to carbohydrates.

Dosage.—15 to 30 Cc. (4 to 8 fluidrams) from 3 to 6 times a day. Children in proportion.

Manufactured by the Arlington Chemical Co., Yonkers, N. Y. U. S. trademark.

LEVULOSE-Schering — Levulosum-Schering. — Fruit Sugar —Fructose.—Levulose Schering is a pure, crystallized fructose (levulose), $CH_2OH.CHOH.CHOH.CHOH.CO.CH_2OH = C_6H_{12}O_6$, absolutely free from dextrose (ordinary glucose).

It is prepared from invert sugar by precipitation as calcium salt, decomposing the precipitate with carbonic acid, and crystallizing. It is a colorless, odorless, slightly hygroscopic, crystalline powder, having a sweet taste compared with that of ordinary cane sugar (saccharose). It is readily soluble in water and in diluted alcohol, slightly soluble in alcohol, insoluble in absolute alcohol and in ether.

Its aqueous solution reduces Fehling's solution and rotates the ray of polarized light to the left.

Actions and Uses.—Levulose is in part at least metabolized in the body by other agencies than those that act on dextrose and most of the other sugars and appears to be sometimes more completely utilized by the diabetic organism than the other sugars.

It has been recommended for the nutrition and for sweetening the food and drink in suitable cases of diabetes, in pulmonary tuberculosis, infantile malnutrition and marasmus.

Dosage.—It is given in diabetes in daily quantities of 30 to 60 Gm. (1 to 2 ounces): in grave forms of the disease the amount is reduced to from 12 to 24 Gm. (3 to 6 drams) daily.

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin, Germany (Schering & Glatz, New York). U. S. trademark No. 21,864

NUTROSE — Sodii Caseinas. — Sodium Caseinate — Casein-Sodium.—Nutrose is a sodium salt of milk casein, containing 65 per cent. of proteids.

It is prepared by dissolving moist casein, freshly precipitated from skimmed milk and washed with water, in solution of sodium hydroxide, evaporating the solution to dryness *in vacuo*, powdering the residue, washing it successively with alcohol and ether, and drying.

It is a coarse, white, odorless and tasteless powder, forming a turbid, adhesive solution with water, having an alkaline reaction toward litmus, but being acid toward phenolphthalein.

Incinerated on platinum foil, it evolves vapors similar in odor to burning horn and leaves at least 3 per cent. of a white, nonvolatile residue, which has an alkaline reaction and colors the Bunsen flame yellow. Casein can be detected by the biuret reaction.

It is incompatible with acids.

Actions and Uses.—Nutrose has been recommended as a nonirritant nutrient in wasting diseases, such as the cachexias in carcinoma, anemia, diabetes, etc., and in acute and chronic febrile ailments, such as pneumonia, typhoid fever and tuberculosis.

Manufactured by Farbwerke, vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York). German patent No. 85,057.

PANOPEPTON.—Panopepton contains 6.33 to 6.38 per cent. of nitrogenous matter (nitrogen x 6.25), 10.05 to 11.92 per cent. of carbohydrates and 17 to 20.9 per cent. alcohol by volume (15 to 18.5 per cent. by weight).

It is said to be prepared from beef and wheat by digestion with gastric and pancreatic juices. The substance obtained by the digestion is mixed in fixed proportion of protein and carbohydrate, sterilized, concentrated *in vacuo* and dissolved in fortified Spanish sherry wine.

It is a light brown fluid, acid in reaction and possessing largely the odor and taste of sherry wine. Its specific gravity is 1.063 to 1.023.

Actions and Uses.—See Medicinal Foods. The nutritive value of 500 Gm. of Panopepton corresponds to 359.1 to 396.3 calories, of which 151.9 to 153.1 are due to protein and 244.4 to 206 to carbohydrates. The same quantity of milk represents 360 calories, of which 84 are due to protein and 98.4 to carbohydrates.

Dosage.—8 to 16 Cc. (2 to 4 fluidrams) several times a day and at bedtime; for infants from a few drops to 2 Cc. (30 minims).

Manufactured by Fairchild Bros. & Foster, New York. U. S. trademark.

PEPTONE—Peptonum.—Peptonum (Pharm. Belgica., edit. 3); Peptona Medicinalia (Pharm. Française, 1908).

Peptone is a product of the peptic or pancreatic digestion of albuminoid substances.

Peptone may be produced artificially as follows: Mince 1000 parts of lean beef freed from bone, etc., and mix it with 4000 parts of water, to this add a solution of 5 parts of pepsin in 1000 parts of water with 50 or 25 parts of hydrochloric acid. The mixture thus prepared is kept at a temperature not exceeding 50° C. (122° F.) until 10 Cc. of the filtrate or the addition of 1.5 Cc. of nitric acid in the cold no longer produces a precipitate. (Formation of a coagulum indicates incomplete peptonization.) The solution is then filtered, neutralized with sodium bicarbonate and evaporated to dryness *in vacuo*. It may be purified if necessary from adherent sodium chloride by dialysis or by precipitation by alcohol washing with ether and drying. By desiccating its concentrated solution upon plates peptone may be obtained in scales. (Brit. Codex.)

Peptone occurs as a white or yellowish-brown amorphous powder or in scales, with a somewhat cheesy but not unpleasant taste and nearly odorless. The pure substances when added to water hisses and froths at the same time evolving heat. It is soluble in water (1 in 20) forming a neutral solution or slightly acid. Aqueous solutions are pale yellow and clear or may be made quite clear by the addition of a little hydrochloric acid. The addition of alcohol precipitates peptone. Aqueous solutions are not coagulated by heat. No precipitate is formed in aqueous solution on the addition of nitric acid or potassium ferrocyanide (difference from albumen) nor is a precipitate formed by solutions of ferric chloride or cupric sulphate nor by saturation with ammonium sulphate or zinc sulphate (distinction from albumoses). The aqueous solutions are levarotatory. Neutral solutions are precipitated by tannin and by various salts of mercury. Acid solutions give precipitates with bismuth potassium iodide, potassium mercuric iodide, bromine water and other precipitants of alkaloids. Peptone is colored yellow with Millon's reagent on warming a red color and precipitate; with cupric sulphate and caustic alkali a violet-red color (biuret reaction). Picric acid gives yellow flakes. Peptone should not be precipitated by lead acetate, alum or hydrogen sulphide. On ignition it should not yield *more than 2 per cent.* ash.

Action and Uses.—Peptone is given as a nutrient in malnutrition and certain forms of dyspepsia. Its value is limited because larger amounts, often even small quantities, cause irritation.

Dosage.—Peptone is given in the form of pastilles, 5 Gm. in each prepared with gelatine. It is administered in rectal alimentation in the form of suppositories or it may be added to rectal enemata.

MERCURIC BENZOATE—Hydrargyri Benzoas.—Hydrargyrum benzoicum (Pharm. Française, 1908), Mercuric Benzoate, $Hg(C_6H_5COO)_2+H_2O$, is the mercuric salt of benzoic acid.

10 Gm. glacial acetic acid is diluted with 100 Cc. water and 10 Gm. yellow mercuric oxide added and the mixture agitated until solution is effected. 14 Gm. sodium benzoate is dissolved in 100 Cc. water and added to the mercury solution. The precipitate which forms is collected and washed with water till free from acid and dried at 100° C. (212° F.). (Pharm. Française, 1908).

Mercuric benzoate is a white crystalline powder, slightly soluble in water, yielding a weakly acid solution, but insoluble in alcohol or ether. At 20° C. (68° F.) a 10 per cent. solution of sodium benzoate dissolves 1 per cent. of its weight of mercuric benzoate. Heated with alcohol it is decomposed into a basic salt of a yellow color. (Pharm. Française, 1908).

A solution of 1 Gm. mercuric benzoate and 0.5 Gm. sodium chloride in 20 Cc. water yield a black precipitate with hydrogen sulphide and with ferric chloride solution it yields a fawn colored precipitate of ferric benzoate.

A solution produced by shaking 1 Gm. mercuric benzoate with 20 Cc. water should not produce more than a faint turbidity when added to silver nitrate solution, acidified with nitric acid (limit of chloride). 2 Cc. of a similar solution when mixed with ferrous sulphate solution and then concentrated sulphuric acid added so as to form a layer beneath, should produce no brown coloration ta the zone of contact of the two solutions (absence *of nitrates*).

Action and Uses.—The same as mercuric chloride.

Dosage.—Mercuric benzoate has been recommended for hypodermic use and in gonorrhea. In urethral cases the solution may be 1-2000 or 1-1000 with an equal quantity of sodium chloride. For hypodermic injection the following may be given: Mercury benzoate, 0.02 to 0.03 Gm.; sodium chloride, 0.01 Gm.; cocaine hydrochloride, 0.15 Gm.; distilled water, 40 Cc.

MERCURIC CYANIDE—Hydrargyri Cyanidum.—Hydrargyrum cyanatum (Pharm. Française, 1908).

Mercuric cyanide, $Hg(CN)_2$ is the mercuric salt of hydrocyanic acid.

Prussian blue and mercuric oxide in water are boiled until the mixture is brown; the mixture is filtered, acidified with hydrocyanic acid, evaporated and allowed to crystallize in a cool place. It is also prepared by the action of hydrocyanic acid on mercuric chloride. Colorless or white, prismatic crystals, odorless, and having a bitter, metallic taste (the salt is exceedingly poisonous). It is darkened on exposure to light. Soluble at 15° C. (59° F.) in 12.8 parts of water, and in 15 parts of alcohol; in 3 parts of boiling water, and in 6 parts of boiling alcohol; very sparingly *soluble in ether*.

When slowly heated in a glass tube, the salt decrepitates, and decomposes into metallic mercury and inflammable cyanogen gas, which burns with a purple flame. On further heating, the blackish residue, consisting of para-cyanogen with globules of metallic mercury, is wholly dissipated.

If 1 part of the salt be gently heated with 1 part of iodine in a dry test-tube it will produce at first a yellow sublimate which afterwards becomes red, and above this a *sublimate of* colorless, needle-shaped crystals.

On adding hydrochloric acid to the aqueous solution of the salt, the odor of hydrocyanic acid is evolved.

A 5 per cent. aqueous solution of the salt should be neutral to litmus paper, and should *not yield*, on the gradual addition of a few drops of potassium iodide test solution, either a red or a reddish precipitate, soluble in an excess of the precipitant, nor should it yield a white precipitate with silver nitrate test solution (absence of mercuric chloride).

If mercuric cyanide be dissolved in an aqueous solution of sodium chloride the addition of phenolphthalein *to this solution* should produce no red coloration (absence of mercuric oxide).

Ammonia should not color an aqueous solution blue (absence of copper) nor should a solution of copper give a brown color or precipitate (absence of potassium ferrocyanide). The presence of large quantities of potassium sulphate may be demonstrated by igniting, leaching the ash and testing the filtrate with barium. Dilute sulphuric acid should not liberate hydrocyanic acid (absence of potassium cyanide). Ammonia should dissolve mercuric cyanide without producing a white precipitate (absence of oxycyanide). (Pharm. Française, 1908).

Action and Uses.—Mercuric Cyanide has been reported to be as actively antiseptic as mercuric chloride and to be less irritating; but this has been questioned. It is used locally and internally like mercuric chloride.

Dosage.—Internally from 0.004 to 0.008 Gm. (1/16 to 1/8 grain); locally, solutions of 1-4000 to 1-2000 may be used for applications to the eye or mucous membranes; 25 to 35 minims of a 1 per cent. solution may be used hypodermically without causing local irritation. Death has occurred from the use of a vaginal injection containing 0.9 Gm. (14 grains) of mercuric cyanide.

In diphtheria and croup it is used in 0.01 per cent. solution as a gargle or internally in doses of 0.0005 Gm. to 0.001 Gm. (0.0077 to 0.0154 grain). In rhinitis fibrinosa it is used on a tampon in 0.04 per cent. solution.

MERCURIC OXYCYANIDE—Hydrargyri oxycyanidum.—Hydrargyrum oxycyanatum (Pharm. Helvetica, edit. 4).

Mercuric oxycyanide, $Hg(CN)_2.HgO$, is basic-mercuric cyanide.

22.2 Gm. mercuric oxide is triturated with 52 Cc. water and 12 Cc. of sodium hydroxide solution (U. S. P.) and then 27 Gm. of pulverized mercuric cyanide is added and the mixture triturated until it becomes colorless or nearly so. If the product is not entirely decolorized heating on a water bath for a short time will complete the reaction. The mixture is allowed to settle, the liquid portion decanted off and the solid residue recrystallized from hot water or is simply washed several times with cold water, collected and dried between filter papers. (Rupp and Goy, Arch. d. Pharm., 1908, p. 369.)

Mercuric oxycyanide occurs as a white, or nearly white, microcrystalline powder which colors moist litmus paper blue. It is soluble in 17 parts water.

Boiled with a mixture of sodium hydroxide, ferrous sulphate and ferric chloride solutions, cooled and then treated with hydrochloric acid, mercuric oxycyanide yields a blue precipitate. A 1 to 20 solution gives a white precipitate with ammonia water soluble in excess *of the precipitant*. Tannic acid solution gives a yellow precipitate. Stannous chloride produces a grey-black precipitate. Hydrogen sulphide and ammonium sulphide produce a black precipitate. When potassium iodide is added to a solu*tion of* mercuric oxycyanide until it becomes yellow the addition of ammonia produces a red color which finally becomes a brown precipitate, which dissolves to a colorless solution in potassium iodide. An aqueous solution should not give a test *for* chloride nor should 0.2 Gm. leave a weighable residue when ignited. (Pharm. Helvetica, edit. 4.)

1 Gm. of mercuric oxycyanide digested with 1 Gm. sodium chloride in 20 Cc. water yields a solution which should require not less than 37 Cc. of tenth normal hydrochloric acid for neutralization, methyl orange or paranitrophenol indicator being used.

Action and Uses.—Mercuric oxycyanide is recommended as a substitute for mercuric chloride. Its antiseptic power is said to be greater and it is claimed to be less irritating than mercuric chloride, because it does not act on albumin to the same extent. It has the advantage over the chloride that it does not corrode steel instruments.

Dosage.—It may be given by hypodermic injections in the same doses as mercuric chloride or may be applied locally in solution, 1-5,000 or slightly stronger.

MERCURIC SALICYLATE—Hydrargyri Salicylas.—Hydrargyrum salicylicum (Pharm. Germanica, edit. 4; Pharm. Helvetica, edit. 4).

Mercuric salicylate, $Hg.C_6H_4.O.COO$. is a mercuric salt of salicylic acid in which one atom of mercury has combined with one molecule of salicylic acid by replacing the hydrogen atoms of the phenolic hydroxyl and carboxyl groups.

Mercuric salicylate may be prepared by precipitating the mercuric oxide from 27 parts of mercuric chloride as directed in the case of Hydrargyri Oxidum Flavum, washing, placing in a flask with a little water and 15 parts of *salicylic acid*, and heating on a water-bath with agitation until the mixture is perfectly white. Collect the precipitate, wash until free from acid, dry at 30° to 40° C. (86°-104° F.), and finally at 100° C. (212° F.).

Mercuric salicylate occurs as a white amorphous powder, tasteless, odorless and neutral to litmus paper, slightly soluble in water or alcohol, but soluble at the ordinary temperature in solutions of sodium hydroxide and sodium carbonate with *formation of a double salt*. From these solutions it is reprecipitated by acids. It is soluble also in warm solutions of chlorides, bromides and iodides. On ignition it is entirely volatilized. Strong mineral acids decompose it, especially on heating, and after this decomposition hydrogen sulphide precipitates black mercuric sulphide from the solution.

When shaken with water the resulting solution gives a violet coloration with ferric chloride.

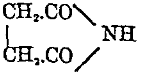
An aqueous solution of mercuric salicylate is not precipitated or colored immediately by hydrogen sulphide or ammonium sulphide.

0.1 Gm. of mercuric salicylate heated in a small tube with a small crystal of iodine produces the characteristic orange to red colored mercuric iodide (Pharm. Germanica, edit. 4). 0.3 Gm. mercuric salicylate mixed with about 3 Gm. sodium chloride and dissolved in 100 Cc. boiling water should upon diluting to 400 Cc., acidifying with hydrochloric acid and passing hydrogen sulphide, yield 0.2 Gm. mercuric sulphide.

Action and Uses.—Antiseptic and antisyphilitic. It has been stated that it is well tolerated by the stomach and that it does not produce salivation, but it may produce some gastrointestinal irritation occasionally, even when used hypodermically. The lack of salivation is probably due to its insolubility and slow absorption and not to any peculiarity of its effects. It is used as a disinfectant and as a remedy in syphilis and in certain skin diseases.

Dosage.—0.003 to 0.008 Gm. (1/20-1/8 grain). For hypodermic injections a suspension in liquid paraffin, one part in 10, is used; before injecting the mixture must be well shaken in order that the insoluble salt may not remain at the bottom. The needle and syringe should be thoroughly cleansed after each injection, as the insoluble drug readily clogs the instrument. At first, 0.65 Cc. (10 minims) of the mixture described should be injected deeply into the gluteal region every fourth day and this may be increased to every second day if no symptomatic evidences of the action of the drug appear. It is used in the form of dusting powder and ointment (1 in 10). A suspension in a mucilaginous vehicle (1 in 300) is used as an injection in gonorrhea, 1 Cc. (15 minims) being injected at a time. As a disinfectant the salicylate is as powerful as mercuric chloride, its great drawback being its insolubility; in order to overcome this difficulty the following formula has been devised: Mercuric chloride, 1 part; sodium salicylate, 3 parts; dissolved in distilled water, 100 parts.

MERCURIC SUCCINIMIDE—**Hydrargyri Succinimidum.**—Mercury succinimide $(Hg(CH_2.CO)_2N)_2 = HgC_8H_8O_4N_2$, is the mercuric salt of succinic acid-imide,



Mercury Succinimide may be prepared by dissolving freshly precipitated mercuric oxide in warm aqueous solution of succinimide and evaporating the mixture, which then deposits crystalline needles. (Schmidt's Pharm. Chemie, vol. II, pt. I, p. 482.) It may also be prepared by adding an alcoholic solution of succinimide containing a few drops of ammonia to an ethereal solution of mercuric chloride (Proceedings A. Ph. A., vol. 40, p. 1029).

Mercury succinimide is a white crystalline powder, soluble in 25 parts hot water and in 75 parts of cold water, and in 300 parts of alcohol. It is very stable in solution. The aqueous solution is not affected by albumin. Mercury succinimide should be protected *from light.* Toward hydrogen sulphide and potassium iodide it reacts as an inorganic mercuric compound. Addition of sodium hydroxide to an aqueous solution of mercuric succinimide produces a yellowish-white precipitate, which on heating is reduced to metallic mercury. If mercuric succinimide is heated with five times its bulk of zinc dust, pyrrol is given off, which may be recognized by the red color which is developed when a pine shaving moistened with hydrochloric acid is held in its vapors.

The aqueous solution must be neutral and should not be affected by solutions of silver nitrate or egg albumin (absence of mercuric chloride and other mercuric salts).

On ignition it should volatilize completely, leaving no residue. If one gram is shaken with 10 Cc. of dry ether, the liquid filtered and the ether removed by evaporation, no residue should remain. If one gram is suspended in ether and hydrogen sulphide passed through the mixture *for some* time, the mercury succinimide will be decomposed, the mercury being precipitated as mercuric sulphide. If the ether be filtered from this precipitate, and evaporated, a residue of succinimide will remain which should have a melting point of 124-125° C.

Actions and Uses.—Mercuric succinimide has the action of other salts of mercury, but its solutions are said to be nonirritating. This preparation is used like other compounds of mercury in the treatment of syphilis.

Dosage.—Mercuric succinimide is used mainly by hypodermic injection, a 2.5 per cent. solution being employed. From ½ to 1 Cc. (8 to 16 minims) of this solution may be injected once daily. Mercuric succinimide may be given by the mouth in doses of 0.01 to 0.015 gm. (1/6 to 1/4 grain).

Non-Proprietary Preparations:

Tabloid Mercury Succinimide (Hypodermic) 1/5 grain: Each tablet contains mercuric succinimide 0.013 Gm. (1/5 grain). Prepared by Burroughs-Wellcome & Co., London and New York.

Hypodermic Tablets Mercuric Succinimide, 1/5 grain: Each tablet contains mercuric succinimide 0.013 Gm. (1/5 grain). Prepared by Sharpe & Dohme, Baltimore Md.

Hypodermic Tablets Mercuric Succinimide, 1/10 grain: Each tablet contains mercuric succinimide 0.006 Gm. (1/10 grain). Prepared by Sharpe & Dohme, Baltimore Md.

MERCUROL—**Hydrargyri Nucleinas.**—**Mercury Nucleinate.**—Mercurol is an organic compound of mercury with nucleinic acid from yeast, containing 10 per cent. of metallic mercury.

It is prepared by adding a solution of mercuric chloride to an alkaline solution of nuc [illegible] xcess of alkali, precipitating the resulting [illegible] by the addition of alcohol and a concentr [illegible] utral salt (sodium chloride), separating the [illegible] and drying it.

It is a brownish-white powder, soluble in water, especially in warm water, insoluble in alcohol. Its watery solution has a distinct metallic taste, a weak alkaline reaction, and is not precipitated by alkalies, nor by albuminous liquids.

The mercury in this preparation resists the action of hydrogen sulphide to a marked degree.

Actions and Uses.—Mercurol does not coagulate albumin; it has marked bactericidal power and possesses the pharmacologic action of soluble mercury compounds.

It is recommended as a local antiseptic application and as an antisyphilitic remedy.

Dosage.—0.3 to 0.12 Gm. (½ to 2 grains).

Manufactured by Parke, Davis & Co., Detroit, Mich. U. S. patent No. 637,355 (Nov. 21, 1899; expires 1916).

MERGAL.—Mergal is a mixture of 1 part of mercuric cholate and 2 parts of albumin tannate put up in capsules. Each capsule said to contain approximately 0.15 Gm. (2¼ grains) of mergal equivalent to 0.05 Gm. (¾ grain) mercuric cholate and 0.1 Gm. (1½ grains) albumin tannate. Mergal contains approximately 4.4 per cent. mercury.

Mercuric cholate is prepared by a patented process, mixed with albumin tannate, and inserted into gelatin capsules in the usual way.

Mergal is a yellowish white, loose, somewhat light powder, insoluble in water and alcohol and almost insoluble in solution of sodium chloride.

When 0.1 Gm. of mergal is shaken with a few drops of saturated solution of cane sugar and underlaid with concentrated sulphuric acid, a purplish red to reddish violet zone is produced.

If 0.2 Gm. of mergal is warmed on the water bath with 10 Cc. of hydrochloric acid for about fifteen minutes and the evaporated water replaced after cooling and filtering, there *results a colorless* or slightly yellowish solution which gives a black precipitate with solution of hydrogen sulphide. The same filtrate gives with a drop of stannous chloride solution an immediate precipitation of metallic mercury.

Mergal should leave no weighable residue on incineration.

0.2 Gm. of mergal boiled for one minute with 20 Cc. of water gives a clear filtrate which is colored dark violet on the addition of a drop of solution of ferric chloride.

0.1 Gm. of mergal when heated with a mixture of 5 Cc. of concentrated sulphuric acid and 5 Cc. of water to boiling, produces a turbid reddish solution. The filtrate after *dilution* with 3 to 4 parts of water and the addition of a drop of solution of copper sulphate gives on careful underlaying or on mixture with an excess of sodium hydroxide solution an evanescent violet-red color. Mergal should be protected from the light.

Actions and Uses.—Mergal is said to pass through the stomach without decomposition and to be decomposed into its constituents in the small intestine, where the mercury is quickly absorbed into the blood and excreted through the kidneys. It is said to be useful in all forms of syphilis and in the para-syphilitic affections, such as tabes and general paralysis. It is also said to be useful for the intermittent *treatment* according to the method of Fournier and Neisser.

Dosage.—One capsule three times a day after meals, gradually increasing to two capsules five or six times a day.

Manufactured by J. D. Riedel Aktiengesellschaft, Berlin, Germany (Riedel & Co., New York). U. S. patent No. 811,193 (Jan. 30, 1906; expires 1923). U. S. trade-mark No. 53,919.

MESOTAN—**Ericin.**—Mesotan is methyl-oxymethyl salicylate, $C_6H_4.OH.COO(CH_2.O.CH_2) = C_9H_{10}O_4$, an ester of salicylic acid, analogous to methyl salicylate.

It is prepared by the action of chlormethyl ether on salicylates thus: $C_6H_4.OH.COONa + CH_2Cl.O.CH_3 = NaCl + C_6H_4.OH.COO(CH_2.O.CH_3)$.

It is a clear, yellowish, faintly aromatic, oily fluid, sp. gr. 1.2 at 15° C. (60° F.) and boiling at about 162° C. (323.6° F.). It is difficultly soluble in water, but readily soluble in the usual organic solvents and miscible with oils in all proportions. Above 100° C. (212° F.) it is decomposed, yielding salicylic acid, formaldehyde and methyl alcohol and it is likewise decomposed to a certain extent by moisture in the air.

Its watery solution gives a violet color with ferric chloride and after heating or exposure to moisture it responds to the usual tests for formaldehyde. Concentrated sulphuric acid colors it red.

It should be kept in a cool place and preserved dry in well-stoppered bottles.

Actions and Uses.—The action of mesotan is similar to that of oil of wintergreen, but it is more irritating to the skin. It is said to be useful in all forms of rheumatism.

Dosage.—Being quite irritating when applied pure to the sensitive skin, it is employed diluted with an equal volume of olive oil, and without friction. Simple application to the affected part, which need not be covered, or, if so, only *slightly, is said to give prompt relief.*

Manufactured [illegible] vorm. Friedr. Bayer & Co., Elberfield, German[illegible] of Elberfield Co., New York). U. S. patent No. 7[illegible]; expires 1919).

METHYL CHLORIDE—Methyl *Chloridum.*—*Methyl* chloride, CH_3Cl, is the hydrochloric acid ester of methyl alcohol. It occurs, in the compressed state, as a colorless liquid, having an ethereal odor, and a sweet taste.

Methyl chloride is insoluble in water, more readily in alcohol, freely in ether and chloroform, and also in acetic acid. *It should* be neutral to litmus paper. At about —25° C. (—13° F.) it has a specific gravity of 0.991, and boils at about —21° C. (—5.8° F.). It burns in *air* with a greenish flame, though it is not highly inflammable. The neutral solution is not precipitated by solution of silver nitrate, nor is there any reaction with potassium iodide and starch paste. In the liquid condition it is a powerful refrigerating agent. At very low temperatures it forms with water a *hydrate,* $CH_3Cl.9H_2O$. *It should not react alkaline* to litmus (absence of ammonia and methylated ammonia—methylamine). It should not immediately form a precipitate with silver nitrate. On evaporating it should leave no residue and emit no odor of methylamine.

Action and Uses.—By its evaporation a temperature of *—23°* (—*9.4°* F.) is produced, while if evaporation be accelerated by means of a current of air a temperature of —55° (—67° F.) may easily be reached. On account of this property it is used as a local anesthetic in the form of a spray, but its use requires caution, since it is apt to produce blisters. The diluted vapor is said to be non-poisonous. Methyl chloride is said to be an efficient general anesthetic, which has practically no influence on the circulation, but fails to produce complete muscular relaxation. It is used as a general anesthetic mixed with ethyl chloride and ethyl bromide.

Dosage.—When sprayed on the skin the part should be partly protected by a thin layer of cotton wool. When used locally cotton wool soaked in liquid methyl chloride may be applied to the skin over the painful area, but care should be taken that blisters are not formed. In order to avoid this a mixture with ethyl chloride has been recommended.

MORPHINE DERIVATIVES

By the substitution of various radicles for hydrogen in morphine, substances are produced, the action of which varies somewhat from that of morphine and which possess, it is claimed, certain advantages over the parent alkaloid. Codeine is a natural substitution product of the same type. The principal derivatives of this class are methyl-morphine (codeine,) ethyl-morphine and diacetyl-morphine.

DIACETYL-MORPHINE—Morphina Acetylata.—Diacetyl-morphine, $C_{17}H_{17}(C_2H_3O_2)_2NO = C_{21}H_{23}O_5N$, is a synthetic alkaloid obtained by the acetylization of morphine.

Diacetyl-morphine was first introduced under the name Heroin by the Farbenfabriken, vorm. Friedr. Bayer & Co. It may be obtained by *heating* morphine with acetylchloride, washing the product with water and dilute solution of sodium carbonate and crystallizing it from alcohol.

It is a white, *odorless* powder, *having a bitter taste, an* alkaline reaction and *melting at* 173° C. (343.4° F.). It is soluble in about 1,60[illegible] parts of water, 25 parts of alcohol, 2 parts of chloroform, 70 parts of ether and 6 parts of benzin; also soluble *in 3* parts of boiling alcohol. It forms salts with acids which are *soluble* in water. On prolonged warming with *mineral acids* it is saponified, splitting *off acetic* acid and reforming morphine.

A solution of 1 part diacetyl-morphine in 100,000 parts of water becomes distinctly turbid on addition of solution of iodine. Its color reactions are similar to those *of* morphine, with *the* following exceptions. It does not liberate *iodine from* iodic acid and does not at *once produce a blue coloration* with potassium ferricyanide and ferric chloride. No blue color is produced by the addition *of* ferric chloride to a neutral solution (1 in 100) made by the careful addition of *dilute sulphuric* acid. Its solutions reduce potassium permanganate.

Actions and Uses.—When given in small doses Diacetyl-morphine and *its* hydrochloride have *apparently no effect on any of the* vital functions except respiration, which it renders *slower, the* volume of the individual *respirations being* increased, but usually not sufficient to compensate the slowing, the result being *a diminution in the total* amount of air respired. In large doses it *may* produce dizziness, nausea and *occasionally constipation,* and, in poisonous amounts, twitching of the extremities, great exhaustion, and dimness of vision may be added. The temperature becomes subnormal and the pulse rapid and thready. The habit is readily formed and leads to the most deplorable results. It is said *not to produce costiveness. (This is not true, according to some observers.)* It is readily absorbed from mucous membranes. It lessens *irritability of the respiratory* center, thus allaying cough, but does *not* depress *the respiration* as much as morphine.

On withdrawing the drug from habitués there is said to be a tendency *to* respiratory failure which may be dangerous.

Diacetyl-morphine and its hydrochloride have been recommended chiefly for the treatment of diseases *of* the *air* passages attended with cough, difficult breathing and spasm, such as the different forms of bronchitis, pneumonia, consumption, asthma, whooping cough, laryngitis, and certain forms of hay *fever. It has also* been recommended as an analgesic, in the place of morphine in various painful affections.

Toxic symptoms should be treated by the administration of caffein hypodermically and of hot coffee by the stomach. To *avoid respiratory failure in the treatment of* diacetyl-morphine addiction, it has been suggested to substitute morphine for *the* diacetyl-morphine *and then treat the patient* for morphine addiction.

Dosage.—See Diacetyl-morphine Hydrochloride.

Proprietary Preparation:

HEROIN.—A name applied to Diacetyl-morphine, which see.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. trademark.

DIACETYL - MORPHINE HYDROCHLORIDE — Morphinæ Acetylatæ Hydrochloridum.—Diacetyl-morphine hydrochloride, $C_{17}H_{17}(C_2H_3O_2)_2NO.HCl$, is the diacetyl-morphine salt of hydrochloric acid.

It is prepared by dissolving diacetyl-morphine in dilute hydrochloric acid, *concentrating* the neutral solution by *evaporation* and *crystallizing.*

It is a white, crystalline, odorless powder, having a bitter taste, showing a neutral reaction with congo and melting at 230° to *231° C. (446° to 447.8° F.).*

It is soluble in 2 parts of water and soluble also in alcohol, but insoluble in ether.

Its aqueous solutions are precipitated by alkaline hydroxides, *the precipitate being* soluble in excess *of* the *reagent,* and by alkaline carbonates. In other respects the reactions are the same as those given under diacetyl-morphine (which see).

It is incompatable with alkalies and their carbonates, tannic acid and other precipitants *of* alkaloids. It is decomposed by mineral acids, particularly when heated.

Actions and Uses.—See Diacetyl-morphine.

Dosage.—0.0025 to 0.005 Gm. (1/24 to 1/12 grain) to adults three to four times a day, the maximum dose being 0.01 Gm. (1/6 grain). To children it may be given in doses varying from 0.0002 to 0.001 Gm. (1/300 to 1/60 grain), according to the age. Hypodermically *it may be administered in the form of* a 2 per cent. solution in the same doses. It has been applied locally to the throat, to the uterus on tampons, and by suppository for painful pelvic affections generally, but there is no evidence that it produces any local anesthetic action.

Proprietary preparation:

HEROIN HYDROCHLORIDE.—A name applied to Diacetyl-morphine Hydrochloride, which see.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. trademark.

ETHYL - MORPHINE HYDROCHLORIDE — Morphinæ Æthylatæ Hydrochloridum. — Ethyl-morphine hydrochloride, $C_{17}H_{17}NO(OH)\ (OC_2H_5)\ HCl + H_2O = (C_{19}H_{24}O_3ClN + H_2O$, *is the* hydrochloride *of the* ethyl ester *of morphine.*

The product was first introduced by Merck & Co., under the trade name Dionin. It may be *obtained by the action* of ethyl iodide on morphine in the presence of alkali, the basic product being *purified* by crystallization from hot *alcohol,* dissolving the crystals in hydrochloric acid and crystallizing.

It is a white, microscopically *crystalline powder, odorless* and only slightly *bitter. It is soluble* in about 7 parts of water and in 2 *parts* of alcohol, insoluble in ether and in chloroform. It melts completely with decomposition at *125° C. (257° F.).*

It gives the usual reactions for *alkaloids. It is* distinguished *from* morphine salts by its *insolubility* in excess of alkali, and by not producing an immediate blue color, but gradually developing a blue-green coloration, when its solution is added to dilute ferric chloride solution containing a fragment of potassium ferricyanide.

It is incompatible with alkalies and their carbonates and alkaloidal reagents, as potassio-mercuric iodide, tannic acid, picric acid, etc.

Actions and Uses.—It is claimed that this compound acts like morphine without producing constipation, nausea or lassitude. It is the conclusion of some good observers that it possesses no advantage over codeine. Applied to the eye, it causes a local vaso-dilation, leading to acute conjunctival edema.

Ethyl-morphine Hydrochloride is recommended to relieve pain, especially in respiratory affections, as an antispasmodic in whooping-cough, for insomnia and externally in the treatment of corneal affections, conjunctivitis, iritis, etc.

Dosage.—0.015 to 0.06 Gm. (¼ to 1 grain). Externally it is applied in 10 to 20 per cent. solutions.

Proprietary Preparation:

DIONIN.—A name applied to Ethyl-morphine-Hydrochloride, which see.

Manufactured by E. Merck, Darmstadt, Germany. (Merck & Co., New York). German patents Nos. 102,654, 107,225 and 108,075. U. S. trade-mark.

MORPHINE MECONATE.—Morphinæ Meconas.—Morphine meconate, $(C_{17}H_{19}O_3N)_2.C_7H_4O_7.5H_2O$, is the normal salt of morphine, $C_{17}H_{19}O_3N$, and meconic acid, $H_2(C_7H_2O_7)$, a dibasic acid obtained from opium.

Morphine meconate may be prepared by dissolving 10 Gm. crystallized meconic acid in 60 Cc. warm water, adding gradually 24 Gm., or sufficient crystallized morphine alkaloid to produce a neutral solution and evaporating to dryness at a temperature below 80° C. (176° F.). (Hager, 1903, vol. 2, p. 403.)

Morphine meconate occurs in minute colorless crystals or a yellowish white powder, soluble in 34 parts of water, also soluble in alcohol. It contains 66.3 per cent. anhydrous morphine.

Action, Uses and Dosage.—The same as other salts of morphine.

Non-Proprietary Preparation:

Tabloid Morphine Meconate (Hypodermic) 1/8 grain.—Each tablet contains morphine meconate 0.008 Gm. (1/8 grain). Prepared by Burroughs-Wellcome & Co., London, England, and New York.

NEUROCAINE.—Billets of Cocaine, Schieffelin.—

Each billet contains cocaine hydrochloride 0.005 Gm. (1/12 grain), without excipient. The billets are ⅛ inch long, 1/20 inch in diameter and very soluble.

Neurocaine is used for pressure anesthesia or as a local anesthetic in dental practice.

Prepared by Schieffelin & Co., New York. U. S. trademark, No. 43,837.

NOVARGAN — Argenti Proteinas. — Silver Proteinate. — Novargan is an organic silver-albumin compound containing 10 per cent. of silver.

It is a fine yellow powder, soluble in water, forming a practically neutral solution, from which it is not precipitated by sodium chloride, nor affected by the usual reagents for silver salts. Solutions must not be heated and must be protected from the light.

The solution is darkened by hydrogen sulphide or ammonium sulphide, but no precipitate is produced.

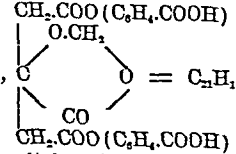
Actions and Uses.—Novargan is a bactericide; it is claimed to be more effective and less irritating than other protein-silver compounds.

It is said to be useful for the treatment of gonorrhea, especially as an abortive in the first stage.

Dosage.—0.5 Cc. (8 minims) of a 15 per cent. solution, by instillation on the anterior portion of the urethra, through a catheter 23 Cm. (9 in.) long, No. 13 French scale, as an abortive.

Manufactured by the Heyden Chemical Works, Radebeul, Germany, and Garfield, N. J. U. S. trademark No. 19,989.

NOVASPIRIN—Methylene-Citrylsalicylic Acid.—Novaspirin is methylene-citrylsalicylic acid,



= $C_{21}H_{16}O_{11}$, a compound of anhydro-methylene-citric acid (see Citarin) and salicylic acid.

Novaspirin is prepared by the action of methylene citric acid dichloride on salicylic acid.

Novaspirin is a white, odorless, crystalline powder, having a faint acidulous taste. It is easily soluble in alcohol, difficultly soluble in chloroform, ether, and scarcely soluble in water. It contains 62 per cent. of salicylic acid.

On heating with caustic alkalies salicylic acid is generated. On prolonged standing with water and more easily with alkalies it is split up into its components. When heated in a test tube it melts with the generation of formaldehyde. On adding dilute acid to the warm alkaline solution, white crystals of salicylic acid are separated.

Actions and Uses.—Novaspirin is not decomposed in the stomach and is said to be non-irritating to that organ, but it is broken up in the intestine into salicylic acid and methylene-citric acid. From its chemical constitution it is reasonable to expect it to have the same systemic actions and uses as salicylic acid.

It is said to be useful in influenza, coryza, tonsillitis, rheumatic conditions, gout and neuralgic conditions.

Dosage.—1 Gm. (15 grains) several times daily.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 858,142 (June 25, 1907; expires 1924). U. S. trademark No. 62,613.

Novaspirin Tablets, 5 grains. Each tablet contains novaspirin 0.33 Gm. (5 grains).

NOVOCAINE.—Novocaine is 1-para-aminobenzoyl-2-diethylaminoethane hydrochloride. $CH_2(C_6H_4.NH_2.COO).CH_2[N(C_2H_5)_2].HCl$, the monhydrochloride of para-aminobenzoyldiethylaminoethanol.

Novocaine crystallizes from alcohol in fine, colorless needles, which melt at 156° C. (312.8° F.). It is soluble in an equal weight of water, but requires 30 parts of alcohol. From the aqueous solution, which is neutral, alkali hydroxides and carbonates precipitate the free base in the form of *a colorless oil*, which soon congeals to a crystalline mass, but solution of sodium bicarbonate is miscible with solutions of novocaine without producing either precipitation or turbidity. The free base crystallizes from diluted alcohol with 2 molecules of water, but from ether or ligroin in the form of anhydrous shining prisms, which melt at 58° to 60° C. (136.4° to 140° F.), while the hydrated base melts at 51° C. (123.8° F.).

The aqueous solution of the salt may be heated to boiling without decomposition, and remains perfectly clear when kept for days in loosely stoppered vials. It gives precipitates even in very dilute solutions with the usual alkaloidal reagents, such as potassium mercuric-iodide, picric acid, potassium iodide, etc.

It is incompatible with alkalies and their carbonates and the alkaloidal reagents.

Actions and Uses.—It is a local anesthetic similar to cocaine, but said to be far less toxic than any of the cocaine substitutes. When injected subcutaneously it is said to exert a prompt and powerful anesthetic action, but the effect is not sustained. This may be remedied by the simultaneous injection of suprarenal alkaloid. Novocaine is not irritant. (See note under Creosote Carbonate.)

It is said to be useful in all cases in which cocaine is indicated.

Dosage.—For infiltration anesthesia, solutions of 0.25 Gm. (4 grains) novocaine in 100 or 50 Gm. (3.2 or 1.6 ounces) physiologic salt solution, with 5 or 10 drops of epinephrine solution (1-1000); for instillations and injections, solutions of 0.1 Gm. (1½ grains) novocaine in 10 or 5 Gm. (150 or 75 grains) salt solution, with or without 10 drops of epinephrine solution (1-1000). In ophthalmology, 1 to 5 to 10 per cent. solution, in rhino-laryngology 5 to 20 per cent. solutions are recommended, with the addition of 6 to 8 drops of epinephrine solution (1-1000) to each 10 Cc. (160 minims). Internally, owing to its feeble toxicity, it may be given in doses up to 0.5 Gm. (7½ grains) to adults.

Manufactured by Farbwerke, vorm. Meister, Lucius & Breuning, Hoechst a. M., Germany (Victor Koechl & Co., New York).

Hypodermic Tablets Novocaine, 1/3 grain. Each tablet contains novocaine 0.020 Gm. (⅓ grain).

NOVOCAINE NITRATE—Novocainæ Nitras.—Novocaine nitrate is, 1-para-aminobenzoyl-2-diethylamino-ethane nitrate, $C_6H_4.NH_2(COO.C_2H_4.N(C_2H_5)_2.HNO=C_{13}H_{21}O_5N_3$, the nitrate of p-aminobenzoyldiethylaminoethanol, the base contained in novocaine.

Novocaine nitrate occurs in small colorless and odorless crystals, soluble in water and alcohol. The aqueous solution is neutral in reaction. Melting point 100°-102° C. (212°-215° F.).

If 0.1 Gm. novocaine nitrate be dissolved in 1 Cc. concentrated sulphuric acid and a solution of ferrous sulphate carefully floated above it, a brown zone is formed at the surface of contact of the two solutions. 1 part novocaine nitrate dissolved in 10 parts water and acidified with nitric acid, should yield no precipitate upon the addition of silver nitrate solution.

Actions and Uses.—As for novocaine; may be prescribed in combination with silver salts, with which it forms no precipitate.

Dosage.—Used in 3 per cent. solutions.

Manufactured by Farbwerke vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York).

U. S. patent No. 812,554 (*Feb. 13, 1906; expires 1923*). *Trademark* No. 53,072.

NUCLEIN, NUCLEIC ACID AND NUCLEATES

Nucleins are modified nucleoproteins obtained by peptic digestion or by treatment with dilute acids. They are split up by the action of alkalies or by tryptic digestion into a protein constituent and a nucleic acid. The exact composition of the protein and of the nucleic acid varies somewhat with the source of the nucleoprotein from which it is derived. The nucleic acids of commerce are apt to contain some protein in combination. They are most commonly made from yeast cells, but have been made, also, from the wheat embryo, the sperm of certain fishes and from the thymus and pancreas glands. In composition they approximate the formula: $C_{40}H_{52}N_{14}O_{25}P_4$. From the wheat embryo products with relatively more nitrogen have been obtained.

Nucleins are colorless, amorphous, insoluble in alcohol and ether and insoluble or slightly soluble in water. They are more or less readily dissolved by dilute alkalies. They give the biuret test and Millon's reaction. They show a great affinity for many dyes, taking them up from aqueous or alcoholic solutions. The term nuclein is sometimes used to designate an impure nucleic acid, which usage has led to confusion as the nucleic acids are bodies of definite composition.

Both nucleins and nucleic acids yield metaphosphoric acid on incineration. On fusion with potassium nitrate and sodium carbonate they yield alkali phosphates.

Actions and Uses.—Nuclein and nucleic acid and nucleates are said to increase the number of white corpuscles, and it has been claimed that this increases the resistance to infections. These results have been obtained by intravenous or hypodermic injection, and on this basis therapeutic deductions have been made; it is doubtful whether we are warranted in applying these conclusions to the administration of the remedy by the mouth.

Nuclein and nucleic acid and nucleates have been used in tuberculosis and various infections, but their true value is undetermined.

They are transformed in the organism into purin compounds and may cause the amount of uric acid in the urine to be increased.

NUCLEIN—Nucleinum.—Nuclein is a modified nucleoprotein obtained by peptic digestion or by treatment with dilute acids.

Actions and Uses.—See Nuclein, Nucleic Acid and Nucleates.

Dosage.—0.5 to 1 Gm. (8 to 15 grains) three times a day.

NUCLEIC ACID.—Acidium Nucleicum.—Nucleinic Acid.—Nucleic acid is an organic acid obtained from nuclein by the action of alkalies or by tryptic digestion.

Nucleic acid is an amorphous, white powder and has an acid reaction. It is readily soluble in ammoniacal or alkaline water with the formation of water-soluble salts. From these solutions it is precipitated by slight excess of hydrochloric acid but not by acetic acid. It is insoluble in alcohol and ether. When chemically pure it does not give the biuret test or Millon's reaction, but a slight response to these reagents does not indicate a degree of impurity incompatible with its use as a medicinal agent.

It should contain between 14.5 and 16.5 per cent. of nitrogen and between 8.5 and 10.5 per cent. of phosphorus, the relative proportion being 4 atoms of P to 14 or 16 N, approximately.

Actions and Uses.—See Nuclein, Nucleic Acid and Nucleates.

Dosage.—0.06 to 0.3 Gm. (1 to 5 grains) three times a day.

Non-Proprietary Preparation:

Nucleinic Acid Merck (from Yeast).—Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York).

SODIUM NUCLEATE.—Sodii Nucleas.—Sodium Nucleinate. Sodium Nucleate is the sodium salt of nucleic acid.

Actions and Uses.—See Nucleir, Nucleic Acid and Nucleates.

Dosage.—Practically the same as that of Nucleic Acid.

Proprietary Preparations:

NUCLEIN, Abbott.—Sodium Tritico-Nucleinate, Abbott. A sodium nucleate derived from the wheat germ.

It is a grayish-white powder, soluble in water and insoluble in alcohol. On incineration it yields approximately 26 per cent. of ash, which is slightly alkaline and readily soluble in water. It contains phosphorus and nitrogen in the ratio of 1 atom of P. to 3.66 N. When the aqueous solution is decomposed by weak hydrochloric acid, a voluminous precipitate of the free nucleic acid is formed.

Actions and Uses.—See Nuclein, Nucleic Acid and Nucleates.

Dosage.—See Nucleic Acid.

Manufactured by the Abbott Alkaloidal Co., Chicago. Not *patented or trademarked.*

Nuclein Solution, Abbott.—Liquor Sodii Tritico-Nucleinatis Abbott.—A solution of Nuclein-Abbott containing approximately 10 Gm. of the salt in 100 Cc. (6 grains in one fluidram) of a menstruum containing 15 per cent. of alcohol. The solution is standardized to contain 1 mg. phosphorus in 1 Cc.

The aqueous extract of the wheat germ is treated with sodium chloride and acid, the precipitate digested with pepsin, neutralized with sodium hydroxide and purified by precipitation with alcohol. The resulting *sodium tritico-nucleinate* is dissolved in distilled water and 15 per cent. of alcohol as a preservative.

Nuclein Tablets, Abbott.—Each tablet is said to contain 0.13 Cc. (2 minims) of Nuclein Solution. Abbott.

OIL OF PINE NEEDLES—Oleum Pini.—Oil of Pine (British Pharm., edit. 8), Oleum Pini Pumilionis (Pharm. Austriaca, edit. 8). Oil of pine needles is the oil distilled from the fresh leaves of Pinus Pumilio, Haenke (British Pharm., edit. 8).

Oil of pine occurs as a colorless or faintly yellowish liquid, having a pleasant, aromatic odor, and a pungent taste. The oil is soluble in 4.8 volumes 90 per cent. alcohol (Hager, 1908). Specific Gravity, 0.865 to 0.875; begins to boil at 165° C. (329° F.). (British Codex, 1907.)

It should rotate the plane of a ray of polarized light from 5° to 10° to the left at 15.5° C. (60° F.) in a tube 100 millimeters long. Not more than 10 per cent. should distil below 165° C. (329° F.).

Action and Uses.—Oil of pine is employed principally as an inhalant with hot water for its stimulating and disinfecting action in catarrh of the respiratory passages, chronic laryngitis and bronchitis. It has been applied locally and given internally in the treatment of chronic rheumatic affections. When added to ether it is said to allay the irritation and diminish the bronchial secretion, which frequently become excessive, during or after the production of anesthesia by the latter drug.

Dosage.—0.05 to 0.3 Cc. (1 to 5 minims). The oil is given internally as a respiratory antiseptic and "expectorant," being taken on sugar, in capsules, or in the form of pastilles. It is rubbed over rheumatic joints, which are then covered with cotton wool, or 4 Cc. (1 fluidram) of the oil may be added to a warm bath.

Vapor Olei Pini.—Oil of pine, 10 Cc.; Magnesium Carbonate, 5 Gm.; Distilled water, sufficient to produce 100 Cc.

Mix the oil with the magnesium carbonate and add the water. A quantity sufficient for one inhalation, 4 Cc. (1 fluidram), is to be placed with 300 Cc. (10 fluidounces) of cold water and 300 Cc. (10 fluidounces) of boiling water in an apparatus so arranged that the air to be inhaled may pass through the solution.

Pine oil inhalation is used as a mild antiseptic in catarrhal affections of the respiratory passages.

OLEORESIN OF PARSLEY SEED—Oleoresina Apii.—Apiol, Green.—An oleoresin obtained from parsley seed by extraction with alcohol.

Parsley seed is extracted with alcohol, the alcohol recovered, and the liquid portion of the residue freed from the solid, waxy matter which separates on standing.

Oleoresin of parsley seed is a greenish, oily liquid, insoluble in water, but soluble in alcohol, ether, and chloroform. Sp. gr. about 1.05.

Actions and Uses.—See Apiol.

Dosage.—0.3 to 1 Cc. (5 to 15 minims) in capsules.

ORGANIC IRON PREPARATIONS

The term, "organic iron" ("masked" or "non-ionic" iron) is confined by modern usage to those organic compounds of iron which do not give the chemical tests of this metal (blue color with potassium ferrocyanide, blue-black color with hematoxylin, etc.) until the structure of the molecule has been destroyed by reagents. The resistance to this destruction varies greatly; some (such as hemoglobin) require incineration or the action of concentrated acids; while others give the iron-tests after treatment with even fairly dilute acids. The organic iron compounds occurring naturally in animal and vegetable tissues (which are often termed "food-irons") belong generally to the more resistant class, while the iron of the synthetic preparations is usually liberated fairly readily. This does not, however, constitute a sharp line of distinction between the two classes, nor is there any good evidence that they differ in therapeutic action. Until this difference is established all organic iron preparations, whatever their source, may be placed in a single class. It is evident, however, that an organic iron (chemically) which is destroyed by 0.2 per cent. hydrochloric acid at the body temperature, cannot be classed as an organic iron in the therapeutic sense. It should also be emphasized that salts of iron (which give the iron tests directly) are classed as inorganic iron, whatever the acid radicle. True albuminates, peptonates, etc., of iron are, therefore, inorganic.

Actions and Uses.—Organic iron preparations are used to increase the hemoglobin in conditions of anemia. Bunge supposed that only organic iron could be absorbed and assimilated by the body, the reputed action of inorganic iron being altogether indirect, and due to its local effects on the alimentary canal. This theory was modified by Abderhalden, to the effect that inorganic iron, while it could not be converted into hemoglobin, nevertheless stimulated the assimilation and conversion of organic iron. The later work, however (Tartakowski) seems to prove conclusively that inorganic iron is assimilated and converted into hemoglobin, and is in so far therapeutically, fully equal to organic iron. Many authors, nevertheless, still adhere to the theories of Bunge and Abderhalden At all events, a real difference exists between the organic and most of the inorganic preparations, namely, in the local irritant and astringent action of the latter, and the absence of these effects in most of the organic compounds. These actions may be desirable in some cases, and undesirable in others. It should also be remembered that organic iron may often be administered in sufficient amount, and most economically, by selecting a dietary rich in iron, such as red meats, egg-yolks, green vegetables, whole wheat, etc.

ORGANS OF ANIMALS

The discovery of the importance of internal secretions has led to extensive clinical trials with preparations of the so-called ductless glands, and other tissues which elaborate, or are supposed to elaborate such internal secretions. Two of these, the thyroid and suprarenal glands, have given decisive therapeutic results and have become official in the Pharmacopeia; preparations of the active principle of the suprarenal are described in this book under the heading of "Epinephrin." The other organ products are scarcely beyond the experimental stage, and may therefore be described together. Their active principles have not been isolated, and they are most commonly used in the form of the powdered dried gland. The gross fat and connective tissue should be removed as completely as possible, and the drying should be conducted at a relatively low temperature. The powder is frequently compressed into tablets. It is recommended that the strength of these should be stated in terms of the dried gland. Since there are no tests for the quality, or even identity, of these powdered products, the physician, unless he can himself supervise their preparation, is forced to rely on the general reputation of the manufacturer.

After the description of each gland a list of such preparations as have been submitted to the Council, and which are being marketed in an unobjectionable manner, is given. For the reasons stated, however, the Council disclaims any responsibility for their quality or identity.

Corpus Luteum

It is generally recognized that one or more of the most important of the internal secretions of the ovaries originate in the corpora lutea and the latter have been tried recently to a considerable extent in some of the classes of cases in which the entire gland has been used. Thus, it is stated that in cases of artificial menopause, following operation, the use of the dried corpus luteum has been followed by great improvement. It may be given in the form of tablets, each of which is composed of a dried corpus luteum, obtained from a pregnant animal, usually a pig; or it may be given as "lutein", in twenty grain doses, three times a day, in some cases given continuously, in others periodically when the discomforts are greatest, and continued for about ten days at a time. The "lutein" is made by squeezing out the corpora lutea from the ovaries of the pig obtained at the slaughter house. The corpora are then rapidly dried, powdered, and compressed into tablets. These preparations are stated to frequently give good results when the ordinary ovarian extract made from the dried tissues of the ovary itself fails.

Corpus luteum has also been recommended in obesity associated with amenorrhea and in other conditions of "ovarian insufficiency" and in dysmenorrhea. This substance also, however, is still of questionable value in these various conditions, the evidence being not yet sufficient for judgment.

Drevet recommends that an extract of the corpora lutea, prepared as follows, be used: 1 kilo of finely divided corpora lutea are macerated in the cold for forty-eight hours with a mixture of 500 Cc. glycerine, 500 Cc. distilled water and 10 Cc. sulphuric acid. The liquid is filtered, neutralized with soda and the precipitate after being washed, is dissolved in acetic acid and again precipitated. The precipitate is then dried in vacuo. Dose of this extract, 0.04 Gm. to 0.08 Gm. (⅔ to 1⅓ grain) gradually increased to 0.12 Gm. (2 grains).

DESICCATED CORPUS LUTEUM—Armour.—Desiccated corpus luteum—Armour, consists of the fresh substance from the corpora lutea from cow's ovaries, removed, dried and powdered without the addition of preservative or diluent.

A yellowish powder, having a peculiar odor. Partly soluble in water.

One part represents approximately 5 parts of the fresh corpus luteum substance. It contains a true lipochrome which may be extracted by alcohol, ether or chloroform. On incineration, it should yield not more than 6 per cent. of ash.

Actions and Uses.—See Corpus Luteum.

Dosage.—0.03 to 0.06 Gm. (½ to 1 grain) twice daily.

Manufactured by Armour & Co., Chicago. Not patented or trademarked.

Mammary Gland

The extracts of the mammary gland are said to have an effect upon the uterus. They have been used in the treatment of profuse and painful menstruation and of uterine and ovarian tumors, but the beneficial results reported can hardly be accepted until confirmed by further observations.

MAMMARY SUBSTANCE—Armour.—Mammary Substance—Armour, consists of the mammary gland of the sheep freed from fat, cleaned, dried and powdered, without the addition of preservative or diluent.

A yellowish to orange colored powder, having a slight peculiar odor. Only partially soluble in water.

One part represents approximately 4½ parts of the fresh mammary gland of the sheep. It contains nucleoproteid which, when treated with dilute sulphuric acid, yields guanin. (S. Fränkel. Descriptive Biochemie, p. 386). Upon incineration, it should not yield more than 9 per cent. ash.

Actions and Uses.—See Mammary Gland.

Dosage.—0.13 to 0.3 Gm. (2 to 5 grains) three times daily.

Manufactured by Armour & Co., Chicago. Not patented or trademarked.

Mammary Substance Tablets-Armour.—Each tablet contains desiccated mammary substance 0.13 Gm. (2 grains).
Dose.—1 to 3 tablets three times a day.

Ovary

The ovaries produce internal secretions which are necessary for the proper functioning of the uterus and which also have obscure effects on metabolism and the nervous system. Diminution or cessation of the activity of the ovaries (as at menopause, natural or artificial) often leads to a variety of nervous symptoms; irregularities in their activities seems to be sometimes accompanied by dysmenorrhea. Ovarian substance has been administered, often with apparently good results, for the relief of symptoms following the natural or artificial menopause and in dysmenorrhea, intermenstrual pain, etc.

OVARIAN SUBSTANCE—Armour. — Ovarian Substance—Armour, consists of the entire fresh ovaries (including the corpora lutea) of the hog, cleaned, dried and powdered, without the addition of either preservative or diluent.

A yellowish colored powder having a peculiar odor. Partially soluble in water.

One part represents approximately 6¾ parts of the fresh ovary of the hog. It contains gelatin, mucin, nuclein and the active constituent of the corpus luteum. Upon incineration, it should not yield more than 7 per cent. ash.

Actions and Uses.—See Ovary.

Dosage.—0.06 to 0.2 Gm. (1 to 3 grains) three times daily.

Manufactured by Armour & Co., Chicago. Not patented or copyrighted.

Ovarian Substance Tablets-Armour.—Each tablet contains ovarian substance 0.13 Gm. (2 grains).

Dose.—*1 to 2 tablets three times a day.*

PARATHYROID GLAND

The parathyroid gland, even in small doses, has a pronounced action on the course of the tetany resulting from the removal of or injury to the parathyroid glands. Its use checks the convulsions and removes the feeling of fear, the nausea and diarrhea and has undoubtedly at times greatly prolonged life or saved it while the injured parathyroid glands regained their functions. The fresh gland seems to be more active than the dried commercial preparation.

The drug has been used most successfully in tetany following removal of the parathyroids; its use in idiopathic and other non-operative forms of tetany has been much less satisfactory.

DESICCATED PARATHYROID GLAND—Armour.—Desiccated Parathyroid Gland—Armour, consists of the exterior parathyroids of the ox freed from fat, cleaned, dried and powdered, without the addition of preservative or diluent.

A light yellow powder, having a peculiar odor. Partly soluble in water.

One part represents approximately six parts of the fresh tissue. On incineration it should yield not more than 7 per cent. ash. It contains very small amounts of organically combined iodine.

Action and Uses.—See Parathyroid Gland.

Dosage.—0.006 Gm. (1/10 grain) four times a day.

Manufactured by Armour & Co., Chicago.

Parathyroid Tablets, Armour.—Each tablet contains desiccated parathyroid gland 0.003 Gm. (1/20 grain).

PAROTID GLAND

The suggested uses are similar to those for the mammary and ovary; it has been recommended in artificial menopause, intermenstrual pain and other conditions in which the ovary or corpus luteum are used.

DESICCATED PAROTID GLAND—Armour. — Desiccated Parotid Gland—Armour, consists of the fresh parotid gland of the ox, freed from fat, cleaned, dried and powdered, without the addition of either preservative or diluent.

A yellowish colored powder, having a slight peculiar odor. Partially soluble in water.

One part represents approximately 5 parts of the fresh parotid gland of the ox. Upon incineration, it should yield not more than 7 per cent. ash.

Actions and Uses.—See Parotid Gland.

Dosage.—0.2 to 0.3 Gm. (3 to 5 grains) three times daily.

Manufactured by Armour & Co., Chicago. Not patented or trademarked.

Parotid Tablets-Armour.—Each tablet contains desiccated parotid gland 0.13 Gm. (2 grains).

Dose.—*1 to 2 tablets three times a day.*

PITUITARY GLAND

The removal of this body in animals is followed by symptoms of motor disturbances, depression, emaciation, and rapid death. The infundibular portion of the gland causes, when injected *intravenously*, a rise of blood pressure and slows but strengthens the action of the heart. It contains a substance soluble in water, and not destroyed by boiling, which is stated to cause dilation of the renal vessels and a marked increase in the secretion of urine. The gland has been found to be abnormal in many cases of acromegaly and so is believed by many to have an internal secretion acting on the growth of bones. The anterior lobe is claimed to have properties similar to those of thyroid extract.

The drug has a doubtful effect on the circulation when given by the mouth, but the infundibular portion may be useful in cardiac debility. An extract of this part of the gland has been recommended as a diuretic. The results of the use of the gland in acromegaly are uncertain, but the output of phosphates is said to be increased. It may be given at the first symptom of debility or functional disturbances.

DESICCATED PITUITARY SUBSTANCE (ANTERIOR LOBE)—Armour.—Desiccated pituitary substance (anterior lobe)—Armour consists of the anterior lobe from the pituitary of the ox, separated, dried and powdered without the addition of preservative or diluent.

A light grayish yellow powder, having a slight peculiar odor. Partly soluble in water.

One part represents approximately 4.5 parts of the fresh substance. On incineration, it should yield not more than 6.5 per cent. ash.

Action and Uses.—See pituitary gland above.

Dosage.—0.05 to 0.20 Gm. (1 to 4 grains) in powder or tablet.

Manufactured by Armour & Co., Chicago.

DESICCATED PITUITARY SUBSTANCE (POSTERIOR LOBE)—Armour.—Desiccated pituitary substance (posterior lobe)—Armour consists of the posterior lobe from the pituitary of the ox, separated, dried and powdered without the addition of preservative or diluent.

A light grayish yellow powder having a slight peculiar odor. Partly soluble in water.

One part represents approximately 4.5 parts of the fresh substance. On incineration, it should yield not more than 6.2 per cent. of ash.

Action and Uses.—See pituitary gland.

Dosage.—0.05 to 0.20 Gm. (1 to 4 grains) in powder or tablet.

Manufactured by Armour & Co., Chicago.

PITUITARY BODY, DESICCATED—Armour.—Desiccated pituitary body—Armour, *consists of the dried substance of* the entire pituitary body of the ox, including the infundibulum and the anterior and posterior lobes without the addition of preservative or diluent. It is said to contain all the active principles naturally existing in the gland.

A light yellowish-gray powder, practically odorless and tasteless. One part represents approximately 4 parts of fresh gland.

Actions and Uses.—See pituitary gland.

Dosage.—0.06 to 0.2 Gm. (1 to 3 grains) three times a day.

Manufactured by Armour & Co., Chicago. Not patented or trademarked.

Pituitary Tablets.—Armour.—Each tablet contains desiccated pituitary body 0.06 Gm. (1 grain).

RED BONE MARROW

Red bone marrow consists largely (more than 90 per cent.) of fat. In new born animals a third or more of this fat consists of lecithin. The marrow of the bones of new-born animals contains iron (up to 1 per cent. or more) in various forms of organic combination. Both lecithin and iron decrease rapidly in the first weeks after birth. The commercial preparations contain very variable amounts of these constituents.

Action and Uses.—Red bone marrow is supposed to stimulate the formation of red blood corpuscles; whatever action it may have in this direction is probably due largely to the iron and lecithin which it contains.

It is recommended in simple and pernicious anemias.

EXTRACT OF RED BONE MARROW.—Extract of red bone marrow is a glycerin extract of the red marrow of bones. It contains about 2 per cent. of proteids, about 0.1 per cent. of lecithin and about 85 per cent. of glycerin.

It is a brownish liquid of an agreeable aromatic taste.

Actions and Uses.—This preparation is claimed to stimulate the formation of the red blood corpuscles.

It is recommended in simple and pernicious anemia, but its value is not yet beyond question.

Dosage.—4 to 8 Cc. (1 to 2 fluidrams) in water, milk or wine, three times a day.

Prepared by Armour & Co., Chicago.

SPLEEN

Spleen has been used empirically in anemia, chlorosis, myxedema and various other diseases with no definite results.

DESICCATED SPLEEN—Armour. — Desiccated Spleen—Armour, consists of the spleen of the calf, freed from fat, cleaned, dried and powdered, without the addition of preservative or diluent.

A dark yellowish colored powder, having a peculiar odor. Partially soluble in water.

One part represents approximately 4¾ parts of the fresh spleen substance. It contains nuclein and iron. Upon incineration, it should yield not more than 7 per cent. ash.

Actions and Uses.—See Spleen.

Dosage.—0.13 to 0.25 Gm. (2 to 4 grains) every three or four hours.

Manufactured by Armour & Co., Chicago. Not patented or trademarked.

Spleen Tablets-Armour.—Each tablet contains desiccated spleen 0.065 Gm. (1 grain).

Dose.—1 to 3 tablets three times a day.

TESTICLE

Subcutaneous injections of testicular extracts were claimed to increase muscular energy from 10 to 20 per cent. Oxidation has been said to be somewhat increased and extracts of the gland have been used in obesity, but the results have been most uncertain. It has also been employed in prostatic hypertrophy and many other conditions.

ORCHIC SUBSTANCE—Armour. — Orchic Substance—Armour, consists of the pulp from fresh ram testicles removed, dried and powdered, without the addition of preservative or diluent.

A light yellow powder, having a peculiar odor. Partly soluble in water.

One part represents approximately 7 parts of the fresh pulp from the ram testicle. Upon incineration, it should yield not more than 10 per cent. ash.

Actions and Uses.—See Testicle.

Dosage.—0.13 to 0.3 Gm. (2 to 5 grains) three times a day.

Manufactured by Armour & Co., Chicago. Not patented or copyrighted.

Orchic Substance Tablets-Armour.—Each tablet contains orchic substance 0.13 Gm. (2 grains).

Dose.—1 to 3 tablets three times a day.

THYMUS GLAND

Little is known as to the functions of the thymus, but it is believed to have an important relation to growth. There also seems to be some relation between the thymus and thyroid, for the former is frequently abnormal in diseases involving the latter (exophthalmic goiter).

The use of thymus is purely empirical. It has been employed in the treatment of exophthalmic goiter, rickets, tuberculosis, hemophilia, and infantile marasmus and atrophy; its use in the latter conditions is said to be the most promising. It is claimed on very doubtful grounds to exert a somewhat favorable effect in certain cases of cancer.

DESICCATED THYMUS—Armour.—Desiccated Thymus—Armour, consists of the fresh thymus gland of the calf freed from fat, cleaned, dried and powdered, without the addition of preservative or diluent.

A very light yellow powder, having a peculiar odor. Partly soluble in water.

One part represents approximately 5 parts of the fresh thymus gland. It is rich in nucleoprotein and in lymphoid tissue. Upon incineration, it should yield not more than 12 per cent. ash.

Actions and Uses.—See Thymus Gland.

Dosage.—0.13 to 0.25 Gm. (2 to 4 grains) three times daily.

Manufactured by Armour & Co., Chicago. Not patented or trademarked.

Thymus Tablets-Armour.—Each tablet contains desiccated thymus 0.065 Gm. (1 grain).

Dose.—2 to 4 tablets three times a day.

ORPHOL—Bismuthi Beta-Naphtholas.—Orphol is bismuth beta-naphtholate, a bismuth salt of beta-naphthol.

Bismuth beta-naphtholate occurs in the form of a brownish or grayish powder without odor, almost tasteless and insoluble in water. It is slightly soluble in alcohol.

1 to 2 Gm. bismuth beta-naphtholate is shaken in a separator during one hour with 25 Cc. chloroform and 25 Cc. concentrated hydrochloric acid, and then 50 Cc. water added and again shaken. The chloroform solution drawn off and the acid mixture extracted with three more portions of 10 Cc. chloroform and the combined extracts evaporated and dried to constant weight over sulphuric acid, a residue should remain weighing at least 15 per cent. of the material used, and should respond to tests of identity for beta-naphthol.

The acid solution from which the naphthol has been extracted is transferred to a beaker, diluted to 200 Cc., heated to boiling, ammonia water added till turbidity appears, then sufficient hydrochloric acid to clear up the turbidity and then 50 Cc. of 10 per cent. ammonium phosphate solution is added to the boiling liquid. The precipitate is allowed to subside, the clear liquid decanted through a tared porcelain Gooch crucible, the precipitate washed with hot water by decantation and finally transferred completely to the crucible. The precipitate and crucible are dried, placed in a nickel crucible, and exposed to the full heat of a bunsen flame till the weight is constant. The weight of the [illegible] hosphate multiplied by 0.6869 should yield a [illegible] bismuth, Bi) equal to not less than 60 per [illegible] taken.

1 to 2 Gm. bismuth beta-naphtholate is weighed to a small asbestos plugged percolating tube. 5 Cc. chloroform added, mixed by means of a glass rod, and allowed to percolate into a tared dish. When the liquid ceases to drop, a further portion of 5 Cc. of chloroform is poured into the percolator and also allowed to percolate into the tared dish. The stem of the percolator is washed with a little chloroform, and the combined washings and the percolates allowed to evaporate spontaneously and the residue brought to constant weight over sulphuric acid. The residue should not exceed 1 per cent. of the material taken.

Actions and Uses.—Bismuth beta-naphtholate is decomposed into its constituents in the intestines, where it exerts the effects of bismuth salts and of beta-naphthol. Hence it is used in catarrhal and fermentative gastroenteric disorders, such as gastritis, dysentery, diarrhea, etc. (See note under Betanaphthol Benzoate.)

Dosage.—For children 0.1 to 0.3 Gm. (1½ to 5 grains) and for adults 1.5 to 5 Gm. (22 to 75 grains) daily.

A mixture of beta-naphtholate with acacia should be avoided as a viscid precipitate rapidly becoming hard is likely to be formed.

Manufactured by the Chemische Fabrik von Heyden, Radebeul near Dresden, Germany (Schering & Glatz, New York). U. S. patent No. 516,358 (March 13, 1894; expires 1911)). U. S. trademark No. 27,482.

Orphol Tablets.—Each tablet contains orphol, 0.3 Gm. (5 grains).

ORTHOFORM-NEW — Meta-Amido-Para-Oxybenzoate of Methyl.—Orthoform-new is methyl meta-amino-para-oxybenzoate, $C_6H_3.NH_2.OH.COO(CH_3)$, 3:4:1 = $C_8H_9O_3N$, the meta-amino-para-oxybenzoic acid ester of methyl alcohol.

It is prepared by the nitration of para-oxybenzoate of methyl and reduction of the nitro-product obtained.

It occurs in a fine, white, crystalline powder, neutral in reaction, and melting at 141° to 143° C. (285.8° to 289.4° F.), odorless and tasteless. It is scarcely soluble in water, but soluble in 5 or 6 parts of alcohol and 50 parts of ether. It is decomposed by boiling with water or by warming with alkalies or their carbonates, into methyl alcohol and paroxybenzoic acid. When crystallized from chloroform it sometimes assumes the form of white crystals melting at 110° to 111° C. (230° to 231.8° F.) returning on melting to the ordinary form.

The filtrate obtained after shaking a small portion with water produces a fugitive color with ferric chloride and should not give a reaction with silver nitrate. A solution of 0.1 Gm. in 2 Cc. of water by the aid of hydrochloric acid is colored yellowish red on addition of sodium nitrate and then deposits a yellow precipitate, deepening to red on exposure to the air.

It is decomposed by heating with water; it is incompatible with alkalies and their carbonates.

Actions and Uses.—Orthoform-new is a local anesthetic, resembling cocaine in its local action, but not penetrating the tissues on account of its insolubility. It has practically no action on the unbroken skin and produces no irritation except slight corrosion about the place of application. It is somewhat antiseptic and practically non-toxic in the usual doses.

It is used internally to relieve the pain of gastric ulcer. Since it acts only on ulcerated surfaces, the relief of pain has been assumed to be evidence of the existence of an open ulcer. It has been applied locally as an analgesic to wounds of every description. It has been used in dentistry, in nasal catarrh, hay fever, etc.

Dosage.—Internally, 0.5 to 1 Gm. (8 to 15 grains) in emulsion; locally, in substance as a dusting powder or mixed with milk sugar for insufflation, dissolved in ether and mixed with oil for pencilings, or as salve with wool fat, etc.

Manufactured by Farbwerke vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York). U. S. patents Nos. 610,348 (Sept. 6, 1898; expires 1915) and 625,158 (May 16, 1899; expires 1916).

ORTHOFORM-NEW HYDROCHLORIDE. — Orthoform-new hydrochloride, $C_8H_9O_3N.HCl$, is the hydrochloride of methyl meta-amino-para-oxybenzoate.

It is a white, crystalline powder, having an indefinite *melting* point and an acid reaction. It is soluble in 10 parts of water. Its reactions are the same as those of *orthoform-new, except that it* gives a reaction for chlorides with silver nitrate and has an acid reaction; 3.65 Gm. dissolved in 50 Cc. of alcohol require not *less than 17.8* Cc. nor more than 18 Cc. of normal solution of sodium hydroxide to produce a neutral liquid.

Its incompatibilities are the same as those of orthoform-new.

Actions and Uses.—The actions, uses and dosage of this compound are similar to those of orthoform-new, which see.

Manufactured by Farbwerke vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York).

OSMIUM TETROXIDE—Osmium Tetroxidum.—Osmic acid, Osmium anhydride-Osmium tetroxide, OsO_4, the anhydride of a theoretical acid is obtained by the action of nitrohydrochloric acid on osmium.

Osmium tetroxide occurs in the form of white or yellowish crystals which are slowly soluble in water (1-50); it is also soluble in alcohol and ether but the solutions decompose. Osmium tetroxide melts at 40° C. (104° F.) and boils at about 100° C. (212° F.). It vaporizes even at ordinary temperatures yielding very irritating and extremely poisonous vapors, attacking the eyes and lungs. *It is decomposed by* contact with organic substances. (Brit. Codex, 1907).

From aqueous acidified solutions of osmium tetroxide, hydrogen sulphide *precipitates* brown osmium sulphide, OsS_4 which is insoluble in ammonium sulphide. An aqueous solution of osmium tetroxide decolorizes indigo solution. Iodine is liberated from potassium iodide solutions by osmium tetroxide. Treated with sulphuric *acid*, aqueous solutions of osmium tetroxide become yellow, turning to brown and finally becoming blue; tannic acid produces a red color becoming brown; ferric chlorid and alcohol *reduce osmium tetroxide to the metal osmium.*

Action and Uses.—Intraneural injections are used to produce degeneration of nerves for the relief of persistent neuralgias. The treatment is best applied by injecting ½ to 1 Cc. of a fresh 1 to 2 per cent. solution directly into the, preferably exposed, nerve. The result is sometimes immediate, but more commonly it is not complete until after one or two weeks, or it may even fail entirely. If successful, the effects may persist for several months, when it may become necessary to repeat the injection as the cure is rarely, if ever, permanent. The local reaction is always painful, but not serious. It is not advisable, perhaps, to use osmium tetroxide in renal disease.

OVOFERRIN—Ferri Vitellinum Syntheticum.—Ovoferrin is a solution containing 5 per cent. of an artificial proteid-product in which iron is present in the so-called "organic" or "masked" form (a form which does not give the iron-test directly) equivalent to 0.4 Gm. metallic iron to each 100 Cc. The solution also *contains* 9 *per cent.* of alcohol.

Ovoferrin is prepared by modifying serum-albumin by electrolysis, producing a proteid which is classed by the manufacturers as a vitellin, and introducing ferric hydrate into this proteid by heating under pressure. The "vitellin" constituent of this preparation should not be confounded with the well-known vitellin of yolk of eggs.

The solution has a reddish-brown color, little odor, and a flat, slightly aromatic and alcoholic taste.

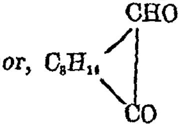
The solution does not give a blue color on the addition of potassium ferrocyanide solution; a blue tint develops slowly if an equal volume of 5 per cent. hydrochloric acid is added to the mixture; a deep blue color develops at once if this mixture is boiled (difference from the egg yolk).

The solution is not precipitated by boiling, but gives precipitates with the alkalies, with which it is incompatible. It is also precipitated on half saturation with ammonium sulphate. It is not precipitated by acids.

Actions and Uses.—Ovoferrin is stated to be not appreciably affected by the gastric juice, a 0.5 per cent. solution of hydrochloric acid liberating its iron very slowly and incompletely. The product ranks with the other forms of artificially masked iron, which are devoid of the local action *of the soluble* inorganic iron salts, and, according to some authorities, are more readily absorbed and utilized.

Dosage.—8 to 16 Cc. (2 to 4 fluidrams) corresponding to 0.03 to 0.06 Gm. (½ to 1 grain) of elemental iron three times a day.

Manufactured by A. C. arnes Co., Philadelphia. U. S. trademark.



OXAPHOR.—Oxaphor is a 50 per cent. solution of oxycamphor, $C_8H_{14}\begin{cases}CHOH\\CO\end{cases} = C_{10}H_{16}O_2$, a derivative of camphor in which a hydrogen atom has been replaced by a *hydroxyl* group.

Oxycamphor is prepared by reducing camphor quinone $C_8H_{14}(CO)_2$ by *means of zinc dust* and acids, extracting the oxycamphor from the liquid product of the reaction with an immiscible solvent and purifying it by distillation with steam.

Oxycamphor is a white crystalline powder, neutral in reaction, melting at 203° to 205° C. (*397.4° to 401° F.*). It is soluble in about 50 parts of cold water, more soluble in warm water, and readily soluble in all organic solvents except petroleum benzin, in which it is soluble, but *from* which it *crystallizes in feathery* aggregations. On prolonged keeping it is prone to undergo decomposition, but it keeps permanently in alcoholic solution. It volatilizes gradually at ordinary temperature and readily with steam.

Oxycamphor, being decomposed on prolonged exposure to the air, is marketed only in the form of the 50 per cent. alcoholic solution under the name of "oxaphor."

Oxaphor should be completely soluble in alcohol and in benzene, forming clear solutions. Its filtered aqueous solution after acidulation with nitric acid should *not afford a precipitate* with silver nitrate or barium chloride. When incinerated it should yield no weighable residue.

Actions and Uses.—Oxaphor is a depressant to the respiratory center, but is said *to have no effect on circulation* and secretion.

It is said to be useful as a substitute for morphine in respiratory disorders, chiefly in cardiac dyspnea and asthma. It is said to have been used with advantage in renal affections, in emphysema, bronchitis, etc. Freedom *from undesirable* side-effects is claimed as an advantage over morphine.

Dosage.—2 to 3 Gm. (30 to 45 *grains*) of *oxaphor* in a little water, wine, syrup or other desirable adjuvant.

Manufactured by Farbwerke vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York). U. S. *patent No.* 610,361 (Sept. 6, 1898; expires 1915).

OXYNTIN.—Oxyntin is a compound of protein and hydrochloric acid containing 5 per cent. hydrogen chloride (absolute hydrochloric acid) in unstable combination.

Oxyntin is prepared by combining hydrochloric acid with the albumin of fresh egg, desiccating the product at low temperature, and standardizing it to a uniform content of hydrochloric acid.

Oxyntin is a dry, granular powder, readily miscible with water, to which it imparts but a slightly acidulous taste.

The method of assay by which the acidity is determined is as follows:

1. About 1 Gm. oxyntin is weighed and mixed with 20 to 25 Cc. water and then *titrated with standard sodium hydroxide,* phenolphthalein being used as the indicator, and the result calculated to hydrogen chloride.

2. (a) About 3 Gm. oxyntin is weighed moistened with sodium carbonate solution in excess, dried, charred and extracted with hot water until free from chloride. The extract is slightly acidified with nitric acid and neutralized by the addition of an excess of calcium carbonate. This solution is titrated with standard silver nitrate potassium chromate being *used as an indicator.* From the result the total chloride content of oxyntin is calculated.

(b) About 3 Gm. oxyntin is weighed and treated as in 2 (a), the addition *of* sodium carbonate being *omitted*. From this result the fixed chloride is calculated.

The volatile chloride is calculated from the difference in the results between (a) and (b), and expressed as hydrogen chloride.

Actions and Uses.—Oxyntin is said to be useful as a substitute for dilute hydrochloric acid in the digestion of protein.

Dosage.—Being *one-half the strength* of diluted hydrochloric acid, U. S. P., oxyntin may be given 0.3 to 1.0 Gm. (5 to 15 grains) dry upon the *tongue* or in capsules, *followed* by a draught of water; or mixed with two or three tablespoonfuls of cold water, plain or sweetened to taste.

Manufactured by Fairchild Bros. & Foster, New York. U. S. trademark No. 50,968.

PARA COTO—(Coto[1]).—Para Coto is the bark of an undetermined South American tree, probably a species of Cryptocarya.

Para Coto occurs in pieces which are *of considerable* size and thickness, 30 cm. (12 in.) wide and 1.5 cm. (⅝ in.) thick. The outer surface is of reddish-brown or cinnamon-brown color. It is sometimes fissured longitudinally and transversely, and sometimes *nearly smooth, with occasional patches* of whitish cork. The inner surface is coarsely striated. It breaks with a fibrous, splintery fracture, and the smoothed transverse section exhibits a thin, brown cork within, which is a narrow cortex separated by a line of *sclerenchymatous cells from the very thick bast,* which is well characterized by the presence of abundant groups of sclerenchymatous cells. The odor is spicy and characteristic, the taste aromatic and pungent. (Para coto is exported from Para at the mouth of the Amazon, and should therefore be called Para coto

---

[1] While commercially, Para coto and coto are sold *indiscriminately*, botanists make a definite distinction between them.

of Para coto is paracotoin, an indifferent iple along with hydrocotoin, methyl hydrocotoin protocotoin, methyl protocotoin (oxyleucotoin), phenyl coumarin, piperonylic acid, volatile oil, resin and tannin.

Para coto is distinguished from coto by the action of nitric acid on the ether extractive matter. In the case of Para coto the result is the formation of a yellow color and in the case of coto a red color appears.

Actions and Uses.—Paracotoin is irritant to the gastrointestinal tract and is similar to cotoin but is weaker. Para coto is used like coto as an appetizer and for diarrhea and dysentery and similar disorders.

Dosage.—0.05 to 0.5 Gm. (1 to 8 grains).

PARACOTOIN.—Paracotoin is a principle, $C_{12}H_8O_4$, from Para coto.

Para coto is extracted with ether and the ether extract distilled. The residue is fractionated by repeated crystallizations from hot alcohol. The first body to separate out is paracotoin.

Paracotoin is a pale yellow, crystalline body, neutral in reaction, tasteless and odorless, melting at 149°-152° C. (300.2°-305.6° F.). It is difficultly soluble in water, but easily in ether, chloroform and boiling alcohol. Concentrated sulphuric and nitric acids dissolve it, forming a yellowish-brown solution. On boiling with a solution of caustic alkalies, a colorless crystalline body, melting at 82°-83° C. (179.6°-181.4° F.), and having the odor of coumarin is formed; this body is acetopiperon (paracumarhydrin) $C_9H_8O_3$ or $C_6H_3\ O_2CH_2.CO.CH_3$, and paracotoic acid $C_{12}H_{10}O_5$ a yellow amorphous mass melting at 108° C. (226.4° F.). Paracotoin fused with potassium hydroxide yields principally piperonylic acid $C_8H_6O_4$.

1 Gm. of paracotoin shaken up with 10 Cc. of fuming hydro bromic acid forms a semi-solid mass of yellow crystals, which on drying over potassium hydroxide lose hydrobromic acid. This residue decomposed with water and recrystallized forms paracotoin, recognized by its crystalline form and melting point.

By gradually adding about 1 Gm. paracotoin to about 10 Cc. concentrated nitric acid, a red-brown solution will result, which, when heated for a short time on the water bath and cooled, deposits a yellow crystalline mass. This product recrystallized from acetone and then from benzene or glacial acetic acid forms golden yellow crystals, melting at 195° C. (323.0° F.). This body is dinitro paracotoin, probably of the formula $C_{12}H_6\ (NO_2)_2O_4$.

An excess of bromine added to a 10 per cent. solution of paracotoin in chloroform cooled to 0° C. produces a deep yellow precipitate, which loses hydrobromic acid, and when recrystallized from alcohol forms the mono-bromide of paracotoin($C_{12}H_7BrO_4$), melting at 200°-201° C. (392°-393.8° F.).

Actions and Uses.—See para coto.

Dosage.—0.06 to 0.18 Gm. (1 to 3 grains).

Actions, Uses and Dosage.—Bitter stomachic, 0.002 to 0.02 Gm. (1/30 to 1/3 grain) before meals.

PERHYDROL—Thirty per cent. Solution of Hydrogen Dioxide.—Perhydrol is a 30 per cent. solution of hydrogen dioxide which is free from acid.

While perhydrol is stable, dilutions of perhydrol rapidly deteriorate unless they are preserved by the addition of some acid.

Actions and Uses.—By suitable dilution a preparation is obtained equivalent to the official solution of hydrogen dioxide. An advantage is claimed for this preparation that it is less irritating on account of the absence of acid. The full strength preparation is said to be useful as an application to nevi, ulcers, gummata, etc. Diluted one-half to two-thirds, it may be applied to syphilitic ulcers, gangrenous processes, ulcerating buboes, in endometritis, suppuration of the middle ear, etc.

Manufactured by E. Merck, Darmstadt, Germany. (Merck & Co., New York). U. S. trademark No. 44,147.

PHENOCOLL HYDROCHLORIDE — Aminoacetphenetidini Hydrochloridum. — Glycocoll-Paraphenetidin Hydrochloride — Phenamine.—Phenocoll hydrochloride is the hydrochloride of amino - acet - phenetidin, $C_6H_4.OC_2H_5NH(CH_2NH_2.CO)HCl = C_{10}H_{14}O_2N_2.HCl$, a synthetic base produced by the combination of phenetidin (paraamidophenetol) and glycocoll (aminoacetic acid). Amino acet-phenetidin (phenocoll), $C_6H_4.OC_2H_5.NH(CH_2NH_2.CO)$, differs from acetphenetidin (phenacetin), $C_6H_4.OC_2H_5.NH(CH_3.CO)$, in that one hydrogen atom in the acetyl group has been replaced by the NH_2 group.

It ion of chloracetylchloride on phenetidin, the reaction with ammonia, neutralizing (phenocoll) so produced with hydrochloric acid, and crystallization.

It is a white, microcrystalline powder, soluble in 16 parts of water at the ordinary temperature, more soluble in hot water, from which it crystallizes in cubes, while from hot alcoholic solution it crystallizes in needles. It is barely soluble in chloroform, ether or benzene (benzol). The free base (phenocoll) obtained by precipitating the aqueous solution with fixed alkalies or their carbonates forms white, matted needles, containing one molecule of water. In its hydrated condition it melts at 95° C. (203° F.), while the anhydrous base melts at 100.5° C. (212.9° F.). It is stable and not chemically affected by acids or alkalies unless subjected to prolonged boiling with these reagents, by which phenocoll is split into phenetidin and glycocoll.

It should produce a clear solution with 30 parts of water, a turbidity indicating the presence of di- or tri-phenocoll, and the solution should not produce a red color with ferric chloride, showing absence of free phenetidin. No ammonia should be evolved on the addition of sodium hydroxide to the warm solution, and the precipitated base should be of a pure white color.

Phenocoll hydrochloride is incompatible with soluble hydroxides or carbonates.

Actions and Uses.—Phenocoll hydrochloride is similar to acetphenetidin (phenacetin) in its effects and acts as an antineuralgic and antipyretic. It is claimed by some observers to be less depressing than other antipyretics derived from aniline, such as acetanilid and acetphenetidin. It has been asserted to have an antiperiodic action and to be efficient as a substitute for quinine in malaria and free from unpleasant by-effects. Its use for this purpose is, however, to be deprecated, for it obviously obscures the symptoms only and does not destroy the malarial parasite. In somewhat larger doses than are usually employed it is said to have a beneficial action in rheumatic fever, but is both more dangerous and less efficient than the salicylates. See Acetphenetidin.

Dosage.—0.3 to 1.3 Gm. (5 to 20 grains) in powder, dissolved in water before taking; hypodermically, in 0.25 to 0.5 Gm. (4 to 8 grains) doses.

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin, Germany (Schering & Glatz, New York). U. S. patent No. 543,214 (July 23, 1895; expires 1912).

PHENOCOLL SALICYLATE.—Phenocoll salicylate, $C_6H_4.OC_2H_5.NH(CH_2NH_2.CO).C_6H_4.OH.COOH = C_{17}H_{20}O_5N_2$, is the salicylate of the synthetic base phenocoll (see phenocoll hydrochloride).

It is prepared by neutralizing a hot aqueous solution of salicylic acid with phenocoll (obtained as described under phenocoll hydrochloride) and cooling the solution.

It forms fine, white, crystalline needles, having a sweetish taste, sparingly soluble in cold water (1 :200), readily soluble in hot water. It gives a violet reaction with ferric chloride.

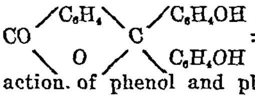
It is incompatible with soluble hydroxides and carbonates and with bodies which are incompatible with the salicylates in general.

Actions and Uses.—It combines the therapeutic action of phenocoll (antipyretic, analgesic, see phenocoll hydrochloride) with those of salicylic acid (antiseptic, antirheumatic).

It is said to be useful in rheumatism, gout, chorea, pleuritis and fevers, especially in influenza, but is more toxic tnan the salicylates alone.

Dosage.—1 to 2 Gm. (15 to 30 grains).

PHENOLPHTHALEIN.—Phenolphthalein,



$$CO\begin{matrix}\diagup C_6H_4 \diagdown \\ \\ \diagdown\ O\ \diagup\end{matrix}C\begin{matrix}\diagup C_6H_4OH \\ \\ \diagdown C_6H_4OH\end{matrix} = C_{20}H_{14}O_4$$

is a product of the interaction of phenol and phthalic anhydride.

It may be prepared by heating together 10 parts of phenol 5 parts of phthalic anhydride and 4 parts of concentrated sulphuric acid for 10 to 12 hours at 115° to 120° C. (239° to 248° F.). The product of the reaction is boiled with water, and the residue dissolved in soda lye. From this solution the phenolphthalein is precipitated by the addition of acetic acid. The precipitate after washing is dissolved in six times its weight of absolute alcohol and the solution decolorized by animal charcoal. A part of the alcohol is then distilled, the mixture filtered and the phenolphthalein separated from the filtrate by the addition of water.

Phenolphthalein occurs as a crystalline or amorphous powder, white or grayish-white, melting at 250° to 253° C. (482° to 487.4° F.). It is soluble in 600 parts of water and in 10 of alcohol. Its solutions in acid liquids are colorless, but turn red when the liquid is alkaline. The red color of the solution disappears if it be boiled with zinc dust, phenolphthalin, $C_{20}H_{16}O_4$, being formed.

Phenolphthalein heated on platinum foil should burn, leaving no residue.

Actions and Uses.—Phenolphthalein acts as a purgative, but appears to possess no further physiologic action. A case of poisoning from taking 1 Gm. (15 grains) is reported.

Dosage.—For adults the average dose is 0.1 to 0.2 Gm. (1.5 to 3 grains) given as powder, in cachets, capsules or pills. It may be given with safety in doses of 0.5 Gm. (8 grains), and these doses seem to be necessary to secure its effects in bedridden patients or in obstinate cases.

PHLORIDZIN—Phloridzinum.—Phlorizin.—Phloridzin is a glucoside, $C_{21}H_{24}O_{10} + 2H_2O$, from the root of the apple, pear, cherry, etc.

Phloridzin occurs as minute white slightly pinkish crystals, of a silky texture, or as a pale yellow light crystalline powder.

odorless and having a bitter but later a sweet taste. It is sparingly soluble in cold but freely soluble in hot water, from which it crystallizes on cooling. It is soluble in alcohol (1-4) and sparingly soluble in ether. The solutions are lævogyrate. At 100° C. (212° F.) it loses water and at 107° C. (224.6° F.) melts When heated to 130° C. (266° F.) it becomes solid again and then melts again at 17° (338° F.). At 200° (392° F.) it assumes a red color, due to the formation of rufin.

Boiled with dilute acids it is converted into sugar, phlorose and phloretine. Exposed to air in the presence of ammonia it assumes a purple color. Cold concentrated sulphuric acid dissolves it to a yellow solution and at 25°-50° C. (77°-122° F.) it becomes red.

Action and Uses.—Phloridzin destroys malarial parasites. When administered to man or animals, it produces glycosuria of renal origin. Polyuria is also produced. It has been recommended as an antiperiodic in malaria, but its use is not justified in view of the possible injury to the kidney which it may cause. It is used as a means of testing the functional activity of the kidney.

Dosage.—To test the permeability of the kidney 0.005 Gm. (1-12 grain) is dissolved in 1 Cc. (15 minims) of a 0.5 per cent. solution of sodium carbonate and injected hypodermically. Glucose should appear in the urine in from 15 minutes to one-half hour and the secretion of sugar should continue for from two to four hours. The test gains in diagnostic value if the urine of each kidney is collected separately. Phloridzin may be given per os in pills massed with glucose syrup or suspended in a mixture with acacia or tragacanth. The internal dose is 0.3 to 0.6 Gm. (5 to 10 grains).

PICRIC ACID—Acidum Picricum.—Acidum Picricum (Pharm. Française, 1908). Picric acid is 2,4,6-tri-nitro-1-phenol, $C_6H_3O_7N_3$ or $C_6H_2.OH.(NO_2)_3(1:2:4:6)$, an acid obtained by nitrating phenol.

Picric acid occurs as orthorhombic yellow prisms, odorless, but with a very bitter taste, with a specific gravity of 1.81 and melting at 122° C. (251.6° F.). It is explosive when heated to a high temperature. It is slightly soluble in cold water, imparting a yellow color to a very large volume of water. It is soluble in 81 parts water at 20° and in 25 parts at 80°. It is easily soluble in alcohol and in 5.7 parts of dry pure ether it dissolves to an almost colorless solution. (Pharm. Française, edit. 1908.)

Aqueous solutions dye organic matter, such as silk, wool and skin a characteristic yellow, but do not dye vegetable fibre.

1 part picric acid dissolved in 9 parts water at 60° C. and a warm solution of 2 parts potassium cyanide in 4 parts water when mixed give a red color. This solution on being cooled yields reddish brown plates of potassium picrocyanin or isopurpuric acid $C_8H_4KN_5O_6$.

Ammonium sulphide produces a red color in solutions of picric acid which becomes deeper on heating. (Pharm. Française, edit. 1908.)

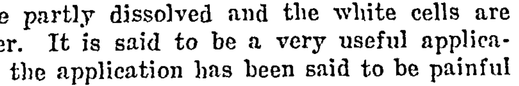
The absence of salts of picric acid is demonstrated by its complete solubility in ether. (Pharm. Française, edit. 1908.)

Action and Uses.—Picric acid is an irritant to the skin and mucous membranes. Taken internally, it may produce nausea, vomiting and diarrhea. The urine is colored red or yellow and may show signs of nephritis. The skin and mucous membranes may be stained yellow and thus jaundice may be simulated. Red blood cells are partly dissolved and the white cells are increased in number. It is said to be a very useful application for burns, but the application has been said to be painful in certain cases. Toxic symptoms have been produced in some instances, especially in children, by absorption through the skin.

Dosage.—0.025 to 0.1 Gm. (½ to 2 grains). A solution containing 6 parts of picric acid, 60 parts of alcohol to 1,000 parts of water has been recommended for local application.

PIPERAZINE COMPOUNDS

PIPERAZINE—Piperazina.—Diethylenediamine.—Ethylene-imine.—Piperazine,



$$NH\left\langle{CH_2.CH_2 \atop CH_2.CH_2}\right\rangle NH + 6H_2O = C_4H_{10}N_2 + 6H_2O,$$

is a synthetic base obtained by the condensation of two $.CH_2.CH_2.$ groups, with two :NH groups, containing 6 molecules of water of crystallization.

It is prepared by the interaction of ammonia on ethylene chloride, treating the complex mixture of different salts produced with sodium nitrate at 60° to 70° C. (140° to 158° F.), purifying the sparingly soluble dinitroso-piperazine, which separates as a scaly crystalline mass, by repeated crystallizations from hot water, and subjecting the pure dinitroso-piperazine so obtained to distillation with an alkali. It is also prepared by several other patented processes.

It forms colorless, lustrous, tabular crystals, hygroscopic, which melt at 44° C. (111.2° F.). It is extremely soluble in water, forming strongly alkaline but non-caustic solutions. It is not so readily soluble in alcohol. It is volatile. It forms soluble salts with acids, and with uric acid it forms a very soluble salt (in 50 parts of water; lithium urate requires 368 parts of water). It is not affected by chromic acid, but is slowly oxidized by potassium permanganate.

In aqueous solution it gives a characteristic scarlet-red precipitate with potassium-bismuth iodide, a white precipitate with Nessler's reagent, and is precipitated light blue by copper sulphate, white by mercuric chloride, lemon-yellow (crystalline) by picric acid and grayish by tannic acid.

It is incompatible with acetanilide, acetphenetidin (phenacetin), alkaloidal salts, nitrites, metallic salts in general and with picric and tannic acids. It should not be exposed to moisture.

Actions and Uses.—A part of the piperazine ingested passes undecomposed into the urine and is claimed by some to form a very soluble compound with the urinary uric acid; others state that the piperazine which is excreted is largely in combination with the stronger mineral acids. It has been shown that urine containing piperazine has no greater solvent power on uric acid than ordinary urine. Piperazine seems to produce no symptoms in man or animals, even when administered in fairly large quantities, although it is stated that, after large doses, tremors, clonic spasms and general depression have occurred.

Piperazine is claimed by the manufacturer to be useful in the prevention of the formation of renal and vesical calculi and for the relief of irritation of the bladder due to excess of uric acid in the urine and in cases of chronic gout, rheumatism, renal colic, etc. The attempt to secure the solution of uric acid in the body by this as well as other remedies has not been successful in the experience of many clinicians. There is no reliable evidence to warrant the acceptance of these claims.

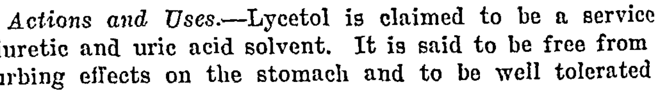
Dosage.—0.3 to 0.6 Gm. (5 to 10 grains); daily dose, 1 to 2 Gm. (15 to 30 grains). Owing to its hygroscopic character, it is impracticable to dispense it in powder; it should, therefore, be dispensed in solution in water, plain or carbonated, but in quantities sufficient for a day's supply only.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 482,108 (expired). Also by Chemische Fabrik auf Actien vorm. E. Schering, Berlin (Schering & Glatz, New York). U. S. patent No. 543,214 (July 23, 1895; expires 1912).

Piperazine Tablets, 16 grains. Each tablet contains piperazine 1.03 Gm. (16 grains).

Prepared by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York).

LYCETOL.—Lycetol is dimethyl piperazine tartrate,



$$NH\left\langle{CH(CH_3).CH_2 \atop CH_2CH\ (CH_3)}\right\rangle NH + H_2C_4H_4O_6 = C_{10}H_{20}O_6N_2,$$

a tartrate of a methyl derivative of diethylenediamine (piperazine).

It is prepared by the distillation of glycerin with ammonium chloride or bromide, reduction of the dimethylpyrazine (isolated from the distillation products) with metallic sodium and converting the base so obtained, after purification, into the tartrate.

It is a white, odorless powder, melting at 250° C. (482° F.), anhydrous, but slightly hygroscopic. It is soluble in water, forming agreeably acidulous solutions.

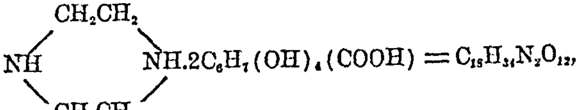
It is incompatible with alkalies which liberate the insoluble free base.

Actions and Uses.—Lycetol is claimed to be a serviceable diuretic and uric acid solvent. It is said to be free from disturbing effects on the stomach and to be well tolerated for long periods.

Dosage.—1 to 2 Gm. (15 to 30 grains), well diluted, and preferably in carbonated water, sweetened with sugar if desired.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York) U. S. patent No. 523,018 (July 17, 1894; expires 1911). U. S. trademark No. 24,722.

SIDONAL—Piperazinæ Quinas.—Piperazine Quinate—Kinate of Piperazine.—Sidonal is piperazine quinate,



$$NH\left\langle{CH_2CH_2 \atop CH_2CH_2}\right\rangle NH.2C_6H_7(OH)_4(COOH) = C_{18}H_{34}N_2O_{12},$$

the normal salt of piperazine and quinic acid.

It is prepared by heating 1 molecule of piperazine with 2 molecules of quinic acid and maintaining the mixture at its melting point for some time, or by dissolving equivalents of piperazine and quinic acid in the smallest practicable quantity of water, concentrating the solution on a water bath, removing the residual water by repeated additions of small quantities of alcohol, evaporating and finally drying the residue in a vacuum.

It forms a white, crystalline powder, melting at 168° to 171° C. (334.4° to 339.8° F.), and having a faint acid taste and reaction. It is very soluble in water and forms salts on mixing the aqueous solution with solutions of alkali carbonates and evaporating to dryness.

It responds to tests for piperazine (precipitate with potassium-bismuth iodide, etc.) and quinic acid.

Its incompatibilities are those of the alkaloidal salts generally.

Actions and Uses.—Sidonal is said to be useful as a uric acid solvent in gout, neurasthenia, etc.

Dosage.—1 to 1.3 Gm. (15 to 20 grains) 5 or 6 times a day, dissolved in water.

Manufactured by Vereinigte Chemische Werke Actiengesellschaft, Charlottenburg, Germany (Victor Koechl & Co., New York). Eng. patent No. 11,420. U. S. patent No. 665,879 (Jan. 15, 1901; expires 1918). U. S. trademark No. 34,706.

POLLANTIN, FALL—Dunbar's Serum.—An antitoxic serum from horses treated with pollen toxin derived from ragweed.

Horses are injected with gradually increased doses of pollen toxin (derived from ragweed), which results in the formation of an antitoxin after two or three months of treatment. The horses are then bled and the strength of the serum is estimated by determining the proportion which will prevent the action of a solution of pollen toxin, of which one drop is barely sufficient to produce a reaction when instilled into the conjunctival sac of a hay-fever patient. The serum is preserved by the addition of 0.25 per cent of phenol.

It is a clear, slightly yellowish liquid, having the odor and taste of a dilute solution of phenol. On standing, the liquid deposits a slight precipitate. The liquid is alkaline in reaction and not irritating to the normal conjunctiva.

It should neutralize the effects of a solution of pollen toxin when mixed with it and dropped into the eye or when a drop is applied immediately after a drop of the toxin solution.

The liquid does not keep well if exposed to the air. When it becomes cloudy or a bad odor develops, decomposition has occurred and the preparation should no longer be used.

Actions and Uses.—It has no pharmacologic action except the neutralization of the pollen toxin. The serum is not intended for use hypodermically. It is employed for the relief of hay fever and it seems to be effective in a proportion of cases. It may be used as prophylactic.

Dosage.—One drop should be instilled by means of a pipette into the outer angle of each eye and one or two drops into one nostril, the other being kept closed, every morning before rising. If the first application causes sneezing or reddening of the mucous membrane of the eye, the directions are to repeat the application, even for the fourth time, if necessary.

Manufactured by Schimmel & Co., Miltitz, near Leipsic, Germany (Fritzsche Bros., New York). U. S. patent No. 745,333 (Dec. 1, 1903; expires 1920). U. S. trademark No. 40,562.

POLLANTIN POWDER, FALL.—A powder obtained by evaporating, *in vacuo*, pollantin serum derived from ragweed toxin at about 45° C. (113° F.) and mixing it with sterilized sugar of milk.

It is a fine, slightly yellowish, almost odorless powder, almost but not entirely soluble in water, and having a slight alkaline reaction. The tests are the same as for the liquid. It should reduce Fehling's solution. The powder keeps well.

Actions and Uses.—The same as those of the liquid.

Dosage.—The powder is applied to the eyes by dusting on the conjunctiva and to the nose by snuffing into one nostril, the other being closed, a piece as large as a lentil.

Manufactured by Schimmel & Co., Miltitz, near Leipsic, Germany (Fritsche Bros., New York). U. S. trademark No. 40,562.

POTASSIUM MERCURIC-IODIDE—Potassii Hydrargyroiodidum.—Potassium mercuric-iodide is a complex salt formed by interaction of mercuric iodide with potassium iodide.

When mercuric iodide is added to an excess of potassium iodide solution a colorless liquid is obtained containing the mercuric iodide as a complex salt, approximately K_2HgI_4 (or $2KI + HgI_2$). Under suitable conditions (Naylor and Chappell, Pharm. J., Mar. 7, 1908, p. 315) the salt having the composition $K_2HgI_4 + 3H_2O$ (or $2KI + HgI_2 + 3H_2O$) may be obtained in yellow needle-shaped crystals.

Potassium mercuric-iodide is deliquescent and is decomposed by water.

Actions and Uses.—The same as mercuric iodide, over which it is claimed to have some advantages because of its solubility.

Proprietary Preparation:

SOLOID MERCURIC POTASSIUM IODIDE.—Tablets said to contain in each tablet mercuric potassium iodide (potassium mercuric-iodide) ($HgI_2 2KI = K_2HgI_4$) 0.113 Gm. (1.75 grains); an excess of potassium iodide, which prevents the decomposition of the potassium mercuric-iodide when water is added, and a trace of coloring matter.

Prepared by Burroughs-Wellcome & Co., London, England, and New York.

PROTAN—Tannin Nucleo-Proteid, Mulford.—Protan is said to be a chemical combination of casein with tannic acid containing about 50 per cent. tannic acid.

It is made by adding a solution of tannic acid to an alkaline solution of casein, collecting and drying the precipitate. Protan is a light brown powder, tasteless, and free from astringent action on the mouth and stomach; insoluble in water or dilute acids, and does not coagulate albumen or precipitate pepsin or peptones.

When shaken with water and filtered, a colorless solution should be obtained, which should give not more than a faint trace of color with ferric chloride solution, showing absence of more than traces of free (uncombined) tannic acid.

The resistance of Protan to the action of the gastric juice may be shown by mixing 2 Gm. (dried at 100 degrees C.) with 40 Cc. 0.2 per cent. hydrochloric acid containing ten times the theoretical amount of 1 :3000 pepsin necessary to digest the proteid present, warming to 40 degrees C. for six hours, filtering off the residue, drying and weighing; 60 to 70 per cent. of the amount taken may thus be recovered.

The tannin may best be determined by difference, the casein being determined by decomposing it by the Kjeldahl-Gunning method and estimating the nitrogen.

Actions and Uses.—It is employed as an intestinal astringent in all forms of diarrhea.

Dosage.—For infants and children, 0.3 to 0.6 Gm. (5 to 10 grains) every hour; in acute catarrhal diarrhea (cholera morbus), 1 to 2 Gm. (15 to 30 grains) every one or two hours; in chronic diarrhea, 1.3 to 2 Gm. (20 to 30 grains) every hour or two hours.

Manufactured by the H. K. Mulford Co., Philadelphia. Not patented. U. S. trademark No. 38,016.

Friable Tablets Protan, 2½ grains.—Each tablet contains protan, 0.16 Gm. (2½ grains).

Friable Tablets, Protan, 5 grains.—Each tablet contains protan, 0.32 Gm. (5 grains).

Friable Tablets, Protan, 7½ grains.—Each tablet contains protan, 0.48 Gm. (7½ grains).

Protan and Opium Tablets, No. 1.—Each tablet contains opium 0.005 Gm. (1/12 grain) and protan 0.162 Gm. (2½ grains).

Protan and Opium Tablets, No. 2.—Each tablet contains opium 0.03 Gm. (½ grain) and protan 0.5 Gm. (7½ grains).

PROTARGOL—Protein Silver Salt.—Protargol is a compound of albumin and silver containing 8.3 per cent. of silver in organic combination.

According to the patent specification insoluble protein silver compounds, obtained by treating protein bodies with silver salt, are rendered soluble by treatment with a solution of albumoses.

It is a light-brown powder, soluble in twice its weight of cold water, producing a solution which is not affected by the ordinary precipitants of silver salts, such as alkalies, sulphides, chlorides, bromides, iodides, nor by heat.

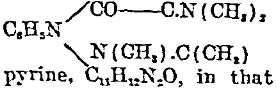
Ammonium sulphide gives a dark color to the solution without precipitation. Addition of strong hydrochloric acid produces a precipitate [illegible] soluble in a large quantity of water. A [illegible] uric acid is not colored blue by dipheny[illegible] with picric acid and picrates and with [illegible] hould not be exposed to light. It is precipitated by cocaine hydrochloride, but this is prevented by addition of boric acid.

Actions and Uses.—Protargol is claimed to be a non-irritant bactericide and antiseptic. It is said to be useful in acute and chronic gonorrhea as a non-irritant substitute for silver nitrate and in diseases of the mucous membranes of the eye, ear, nose and throat, and particularly in the treatment of conjunctivitis.

Dosage.—From 0.25 or 1 per cent. solution in acute gonorrhea, to 5 or 10 per cent. instillations in chronic cases, in cystitis and urethritis; in solutions of 1:1000 to 1:2000 as irrigations. Used also in form of bougies and tampons (5 to 10 per cent.). Its solutions in water are made by pouring on the protargol a little *cold* water, stirring into a thick paste, and gradually adding the remainder of the water under stirring; or by sprinkling the protargol on the surface of the whole of the water (cold) and setting it aside until solution occurs.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 615,970 (Dec. 13, 1898; expires 1915). U. S. trademark No. 30,882.

PYRAMIDON.—Dimethylaminoantipyrina.—Pyramidon is phenyl-dimethyl-dimethylamino-pyrazolon,



$$C_6H_5N\begin{cases}CO\text{——}C.N(CH_3)_2\\N(CH_3).C(CH_3)\end{cases} = C_{13}H_{17}N_3O,$$

differing from antipyrine, $C_{11}H_{12}N_2O$, in that a dimethylamino group, $N(CH_3)_2$, has replaced a hydrogen atom of the pyrazolon nucleus.

It is prepared by the reduction of nitroso-antipyrine to amido-antipyrine and treating this with methyl chloride or iodide.

It forms small, colorless, slightly alkaline crystals, melting at 108° C. (226.4° F.); almost tasteless; soluble in 11 parts of cold water and readily soluble in alcohol, ether and benzene. Its aqueous solution saturated at 70° C. (158° F.) *deposits oily globules of pyramidon on boiling.*

Ferric chloride colors the neutral or slightly acidulated solution of pyramidon a bluish violet color; nitrous or nitric acid produces a fugitive blue-violet color; silver nitrate produces an intense violet coloration when added to the aqueous solution, followed by the formation of a black precipitate of metallic silver, and the same color is produced by platinum chloride, by ammonium persulphate and by lead dioxide. In hydrochloric acid solution pyramidon gives a fine crystalline double salt with mercuric chloride.

Its incompatibilities are in general the same as those of antipyrine. Oxidizing agents (also acacia) often produce colored solutions.

Actions and Uses.—Pyramidon acts as an antipyretic and anodyne, like antipyrine, but is effective in smaller doses. The action, while somewhat slower at the beginning, is more lasting. It is claimed to be devoid of harmful influences on the blood, heart or kidneys. It is said to be useful, particularly in the chronic fevers of tuberculosis, as well as in the acute febrile conditions incident to typhoid fever, erysipelas and pneumonia. In the treatment of infectious fevers, it, like other *antipyretics, should be cautiously employed.* See Acetphenetidin.

Dosage.—0.3 to 0.4 Gm. (5 to 6 grains), most conveniently in the form of tablets, a single dose usually sufficing for 24 hours.

Manufactured by Farbwerke vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York). U. S. patent No. 579,412 (March 23, 1897; expires 1914).

PYRAMIDON ACID CAMPHORATE.—Pyramidon acid camphorate, $C_{13}H_{17}N_3O.C_{10}H_{16}O_4$, is an acid salt of pyramidon and camphoric acid.

It is prepared under the same conditions as the neutral salt.

It is a white, crystalline powder of acid reaction, melting (indefinitely) at 84° to 94° C. (183.2° to 201.2° F.); soluble in 20 parts of water or in 4 parts of alcohol.

It gives the characteristic reaction of pyramidon (which see) with silver nitrate. If the solution in hot water is made alkaline with caustic soda, the pyramidon may be shaken out with chloroform; if the residual aqueous liquid is then acidified with sulphuric acid the camphoric acid (melting point 186° C., 366.8° F.) may be shaken out with ether.

Actions and Uses.—The acid and neutral salts combine the antipyretic action of pyramidon with *the antihidrotic action* of camphoric acid. It is claimed that in these compounds the respective action of *the component is modified,* the antihidrotic effect of the camphoric acid being materially increased, while the toxicity of the pyramidon is diminished; but the latter statement is hypothetical. In the neutral salt the antipyretic action of the pyramidon predominates; in the acid salt the antihidrotic effect of the camphoric acid.

They are said to be especially useful in the febrile conditions of phthisis, attended by profuse sweating. See Pyramidon.

Dosage.—0.75 to 1 Gm. (12 to 15 grains), given in powders or aqueous solution.

Manufactured by Farbwerke vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York). U. S. patent No. 686,999 (Nov. 19, 1901; expires 1918).

PYRAMIDON NEUTRAL CAMPHORATE.—Pyramidon neutral camphorate $(C_{13}H_{17}N_3O)_2.C_{10}H_{16}O_4$, is a neutral salt of pyramidon and camphoric acid.

It is prepared by combining its components with the aid of suitable solvents, under exclusion of light, moisture and heat.

It is a white, crystalline powder, melting (indefinitely) at 80° to 90° C. (176° to 194° F.). It dissolves with acid reaction in 15 parts of water or 2 parts of alcohol.

It gives the characteristic reaction of pyramidon (which see) with silver nitrate. If the solution in hot water is made alkaline with caustic soda, the *pyramidon* may be shaken out with chloroform; if the residual aqueous liquid is then acidified with sulphuric acid the camphoric acid (melting point 186° C., 366.8° F.) may be shaken out with ether.

Dosage.—Neutral camphorate, 0.5 to 0.75 Gm. (8 to 12 grains) given in powders or aqueous solution.

Manufactured by Farbwerke vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York). U. S. patent No. 686,998 (Nov. 19, 1901; expires 1918).

PYRAMIDON SALICYLATE.— Pyramidon salicylate, $C_{13}H_{17}N_3O.C_7H_6O_3$, is a salt of pyramidon and salicylic acid.

It is prepared by combining its components with the aid of a suitable solvent and avoidance of exposure to light, moisture and heat

It is a white, crystalline powder, having an acid reaction and melting indefinitely at 68° to 70° C. (154.4° to 158° F.). It is soluble in 16 parts of water or 5 to 6 parts of alcohol.

The aqueous solution is colored intensely red by ferric chloride, and produces a white precipitate with silver nitrate, the solution assuming a violet color after a short time.

It is incompatible with ferric salts.

Actions and Uses.—It is antipyretic, analgesic and antiseptic, combining the activity of its components.

It is said to be useful in rheumatic and gouty affections, *neuralgia, pleuritis,* etc. See Pyramidon.

Dosage.—0.5 to 0.75 Gm. (8 to 12 grains) in powder or aqueous solution.

Manufactured by Farbwerke vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany *(Victor Koechl & Co.,* New York). U. S. patent No. 680,278 (Aug. 13, 1901; expires 1918).

PYROXYLIN

Pyroxylin is official in the United States Pharmacopœia. For description see the pharmacopeia or the Physicians' Manual of the Pharmacopeia and National Formulary.

CELLOIDIN.—A name applied to a preparation of the character of a purified Pyroxylin, U. S. P.

Celloidin is prepared by solution of pyroxylin in a mixture of alcohol and ether, filtration and recovering the solvent from the *filtrate. It is supplied in shreds immersed in water.*

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin, Germany (Schering & Glatz, New York). U. S. patent No. 299,857 *(expired).*

QUASSIN[1]—Quassine (Pharm. Française, 1908)—Quassinum—Quassin is a bitter principle found in quassia.

The alcoholic extract of Jamaica quassia wood (Quassia U. S. *P.*) is neutralized with magnesia, then acidified with tartaric acid and the alcohol distilled off. The residue is shaken up with chloroform and the solution evaporated to syrupy consistency *and dissolved in a mixture of equal parts of absolute alcohol* and ether. This solution is evaporated and the residue dissolved in as little absolute alcohol as possible, the solution covered with a layer of ether and allowed to evaporate. The crystals which form are recrystallized from alcohol. The product thus prepared consists of two bitter principles *a*-picrasmin ($C_{35}H_{46}O_{10}$) melting at 204° C. (399.2° F.) and *β*-picrasmin ($C_{36}H_{48}O_{10}$) melting at 209-212° C. (408.2° to 413.6° F.).

Quassin crystallizes in oblique rhomboidal needles with a pearly lustre. It is odorless, but has a bitter taste. Its melting point is 210° C. (410° F.) and cooling it forms an amorphous mass. It is soluble in about 400 parts of water at 15° C. (59° F.); in 30 parts alcohol (85 per cent.) and in 21 parts of cold chloroform. *It is very soluble in boiling alcohol,* in acetic acid, and very slightly soluble in ethyl and petroleum ethers. It is soluble in concentrated acids and alkalies, but not in alkaline carbonates. *Continued action of alkalies forms resins (Pharm. Française,* 1908). It is dextrorotatory in its chloroform solution; 4.22 gm. in 100 Cc. chloroform rotating the plane of polarized light to the right with a *specific* rotation of plus 38° 8′. Solutions of quassin are neutral.

It dissolves to a colorless solution in concentrated sulphuric acid, which becomes red on the addition of sugar. (Pharm. Française, 1908).

QUININE DERIVATIVES

ARISTOCHIN — Diquinine carbonic Ester.—Aristoquin—*Carbonyl Quinine.* — *Aristochin* is *quinine* carbonate, $CO(C_{20}H_{23}N_2O_2)_2 = C_{41}H_{46}N_4O_5$, the neutral carbonic acid ester of quinine.

It is prepared according to the patents by acting on quinin dissolved in pyridin or chloroform with carbonyl chloride or by heating together quinine and phenol carbonate in the *proportion* of one molecule of the latter to two molecules of the former.

It forms a white, absolutely tasteless powder, melting at 189° C. *(372.2°* F.) insoluble in water, difficultly soluble in alcohol, more soluble in warm alcohol and chloroform, very sparingly soluble in ether. It is capable of combining with one and two molecules of *hydrochloric acid forming soluble* salts. It is gradually decomposed by acids with liberation of quinine, thus acquiring a bitter taste; hence it is incompatible with acids.

It should be free from bitter taste. As it is decomposed by acids and alkalies with the formation of quinine, it should respond to tests for quinine after such treatment.

Actions and Uses.—The same as those of quinine, but, since it is only slowly acted on by acids, it is said not to produce disturbance of the stomach *and to be much freer from* tendency to production of cinchonism.

Dosage.—The same as that of *quinine,* in powder, mixed with milk sugar, dry on the tongue or suspended in liquids.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). German patents No. 105,666, 134,307 and 137,308. U. S. patent No. 625,075 *(May* 16, 1899; expires 1916).

---

[1] Quassin (amorphous) is not identical with the above and should not be confounded with it.

CHINAPHENIN—Phenetidin Quinine Carbonic Acid Ester.—Chinaphenin is phenetidin quinine carbonate, CO(NH. $C_6H_4OC_2H_5$) ($C_{20}H_{23}N_2O_2=C_{29}H_{33}N_3O_4$, the carbonic acid ester of phenetidin and quinine.

It is prepared by the action of quinin on p-ethoxyphenyl carbamic acid chloride.

It is a white, odorless and tasteless powder, difficultly soluble in water, but readily soluble in alcohol, ether, chloroform and benzene. Acids dissolve it with the formation of soluble salts.

It gives the thalleioquin reaction for quinine salts, but forms a yellow herapathite.

It is decomposed by acids with the liberation of quinine.

Actions and Uses.—Chinaphenin combines the antiperiodic properties of quinine with the analgesic power of acetphenetidin (phenacetin), with the advantage of tastelessness and asserted freedom from symptoms of cinchonism. It has been recommended in febrile diseases, especially la grippe; in spasmodic conditions, such as whooping-cough; in certain forms of malaria and in neuralgia.

Dosage.—Adult: 0.3 to 0.6 Gm. (5 to 10 grains) ordinarily, or 1.5 to 2 Gm. (22 to 30 grains), given in two doses as an antipyretic in neuralgia and malaria; in whooping-cough, 0.13 to 0.3 Gm. (2 to 5 grains), according to age.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 637,839 (Nov. 28, 1899; expires 1916): Vereinigte Chininfabriken. Zimmer & Co., Frankfort a. M., Germany. German patent No. 109,259.

EUQUININE—Quininæ Æthylcarbonas.—Quinine Ethyl Carbonate—Euchinin.—Euquinine is quinine ethyl carbonate, $C_2H_5O.CO.OC_{20}H_{23}N_2O=C_{23}H_{28}O_4N_2$, the quinine ester of ethyl Carbonic acid ester.

It is prepared by the action of chlorocarbonic ethyl ester on quinine, $C_2H_5O.COCl + C_{20}H_{24}N_2O_2=HCl + C_2H_5O.COO.C_{20}H_{23}N_2O$.

It is a light, fleecy conglomeration of delicate, white needles, melting at 95° C. (203° F.) and practically tasteless. It is sparingly soluble in water, but readily soluble in alcohol, ether and chloroform. It is slightly alkaline in reaction, forming well crystallizable, bitter salts with acids. It produces a tasteless tannate.

Its solutions in acidulated water have the characteristic bitter taste of quinine. On heating a mixture of 0.2 Gm. of euquinine, 3 Cc. of solution of sodium hydroxide and a little iodine, the odor of iodoform is manifested. Like quinine its solution in dilute sulphuric acid exhibits strong, blue fluorescence, and it gives also the so-called thalleioquin reaction, but not the herapathite reaction. A solution in nitric acid should not change on addition of either silver nitrate or barium chloride.

It should leave no residue on combustion.

It is incompatible with acids which will develop the bitter quinine taste.

Actions and Uses.—Euquinine is claimed to have the same action as quinine, with the advantage of being tasteless, owing to its insolubility in water and alkaline media.

Dosage.—The same as quinine.

Manufactured by Vereinigte Chininfabriken, Zimmer & Co., Frankfort a. M., Germany (Merck & Co., New York). U. S. patent No. 585,068 (June 22, 1897; expires 1914). U. S. trademarks Nos. 640,977 and 701,523.

QUININE LYGOSINATE—Quininæ Lygosinas.—Quinine lygosinate. $CO(CH:CH.C_6H_4.C_{20}H_{24}N_2O_2)_2=C_{57}H_{60}N_4O_5$, is a quinine compound of dioxy-dibenzal-acetone.

It is prepared by the reaction of quinine hydrochloride with sodium lygosinate.

Quinine lygosinate is a fine, orange yellow, amorphous powder, melting at 114° C. (237.2° F.), having a faintly aromatic odor and a bitter taste, which is gradually developed on account of its sparing solubility in water. It is slightly soluble in water, soluble in 6 parts of alcohol, in 20 parts of hot oil and readily soluble in chloroform and benzene. It is decomposed by acids and alkalies. It contains 70.8 per cent. of quinine.

Burned on platinum foil, quinine lygosinate develops the odor of bitter almonds and leaves no residue. Its alcoholic solution dyes cotton gauze a bright yellow color, which becomes red-brown on drying.

If 1 Gm. quinine lygosinate be shaken with 20 Gm. of 20 per cent. sodium hydroxide solution and extracted twice with 10 Gm. of ether, the quinine remaining after evaporation of the ether should not weigh less than 0.7 Gm. If the alkaline solution thus obtained be acidified, lygosin separates as a thick yellow precipitate.

It is incompatible with acids and alkalies.

Actions and Uses.—It is stated that this preparation is capable of preventing completely the development of cultures of staphylococcus. Given to rabbits by mouth in doses of 1 Gm. per kilo of the body weight it is said to be entirely harmless. It is claimed to be a styptic useful in parenchymatous hemorrhages and free from unfavorable side effects, such as cauterization of the wound surfaces.

Dosage.—It is employed as a dusting powder, in bandages, gauzes, suppositories, in the form of court plaster and in glycerin suspensions.

Manufactured by Vereinigte Chininfabriken, Zimmer & Co., Frankfort a. M., Germany. (C. Bischoff & Co., New York.)

QUININE AND UREA HYDROCHLORIDE.—Quininæ et Ureae Hydrochloridum.—Chininum bihydrochloricum Carbamidum. — Quinine and urea hydrochloride, $C_{20}H_{24}N_2O_2$.-HCl + $CH_4N_2O.HCl + 5H_2O$. is a compound of quinine hydrochloride and urea hydrochloride containing approximately 60 per cent. of anhydrous quinine.

Quinin and urea hydrochloride is prepared by dissolving 400 parts quinin hydrochloride in 300 parts of dilute hydrochloric acid, sp. gr. 1.061, mixing the solution with 60 to 61 parts of pure urea $CO(NH_2)_2$ warming the mixture until dissolved, filtering it through glass wool and setting the filtrate aside for crystallization. After twenty-four hours the crystals are brought on a filter, drained, washed with very cold distilled water, spread on flat plates and dried at room temperature. The mother liquor is evaporated and again set aside for crystallization. The second mother liquor which is colored brown is exposed in a dish to spontaneous evaporation, during which all of the double salt of quinine slowly crystallizes out and may be separated.

The hydrochloride of quinine and urea crystallizes from hot solutions in hard white interlaced four sided prisms. On spontaneous evaporation of a concentrated solution very large transparent prisms are formed. The salt dissolves at ordinary temperature in its own weight of water forming a somewhat viscid straw colored liquid, not altered by exposure to light. During its solution a marked lowering of temperature occurs.

It is not hygroscopic and is unalterable in the air excepting when warmed, the crystals lose their transparency and become yellowish. They fuse at from 70° to 75° C. (158° to 167° F.) with the loss of 10 per cent. of water forming a yellowish liquid which congeals on cooling to a yellow mass. If this mass is allowed to stand in the air it takes up after a few days the whole amount of water expelled and becomes again white. If the melted salt is dissolved in water it may be completely recovered in a crystalline form. It is also soluble in alcohol and from this solution a salt of somewhat variable composition is precipitated by ether.

It is soluble in about 800 parts of chloroform.

Its aqueous solutions are of a strong acid reaction.

A solution of the salt in water 1 to 20 shows no fluorescence, but if one drop of this solution is added to 10 Cc. of distilled water in a test tube a vivid blue fluorescence is developed.

On drying the salt at 125 C. to constant weight and cooling in a desiccator, it should not lose more than 16.5 per cent. of its weight (corresponding to five molecules of water of crystallization).

On ignition the pure salt is slowly consumed, leaving no residue.

Ammonia water, alkaline hydroxides or alkali carbonates throw down from the aqueous solution of quinine and urea hydrochloride a white precipitate of alkaloidal quinine, which when carefully washed with cold distilled water until free from chlorides and dried at a low temperature, should conform to the reactions and tests given in the United States Phramacopeia under quinine. One gramme dissolved in 2 Cc. of distilled water and well shaken in a stoppered test tube with 6 Cc. of ether and 2 Cc. of 10 per cent. ammonia water should be dissolved completely and no crystals should separate out from the ethereal solution on standing for six hours. If the ethereal stratum is removed to a tared beaker and the contents of the test tube washed successively with three portions of 5 Cc. each of ether and these ether washings also added to the tared beaker, the alkaloidal quinine remaining after evaporating off the ether, dried at 125 C. to constant weight, should weigh not less than 0.592 Gm.

If 2 Gm. of the salt be dissolved in a test tube in 4 Cc. of distilled water, the solution cooled and 4 Cc. of nitric acid U. S. P. (free from nitrous acid) be added, the solution quickly cooled again in ice water and the cold mixture set aside at a low temperature, separation of crystals will commence after a few minutes and crystallization will be completed after the solution has stood in a cold place over night. The crystals may be separated by the use of a small glass funnel provided with a pellet of glass wool. The test tube should be washed with three portions of 2 Cc. each of cold diluted nitric acid 1 and 1 and the acid carefully poured over the crystals in the funnel, drop by drop, to remove all traces of quinin. The remaining crystals should consist of urea nitrate. This is demonstrated by taking 3 Cc. of water, heating in the test tube in which the crystals have been crystallized, and after carefully draining off the acid which may be held back by the stem of the funnel, pouring the hot water slowly on the crystals in the funnels and repeating with another 2 Cc. of hot water. The resulting well-mixed solution is divided into two equal parts in two test tubes and cooled. To the first is added from a pipette 10 drops of solution of mercuric nitrate, U. S. P., and then, gradually, normal solution of sodium hydroxide until only a slightly acid reaction is obtained, when a copious white precipitate should result.

The second part of the filtrate is made strongly alkaline by the use of a solution of sodium hydroxide, 1 in 4, and to the resulting clear liquid is added 2 Cc. of a strong solution of sodium hypochlorite. The mixture is warmed to about 40 C., when a development of gas will take place at once.

Actions and Uses.—Quinine and urea hydrochloride has the actions of quinine. It is non-irritating when injected hypodermically. Recent investigations have shown that when injected hypodermically or when applied locally to mucous membranes it exerts an anesthetic action similar to that of cocaine. It is reported that the anesthesia is in some cases prolonged for several days.

Quinine and urea hydrochloride is said to be especially useful in the treatment of malaria by hypodermic injections. It has also been applied as a substitute for cocaine in the production of local anesthesia for operations.

Dosage.—The same as Quinine. For the production of local anesthesia injections of a solution of from ¼ to 1 per cent. strength are used. The ¼ per cent. solution is said to be free from the risk of producing fibrous indurations, which sometimes occurs with the stronger solution. For application to mucous membranes solutions varying in strength from 10 to 20 per cent. should be used.

SALOQUININE—Quinine Salicylic Ester.—Salochinin—Salicylquinine.—Saloquinine is quinine salicylate, $C_6H_4.OH.COO(C_{20}H_{23}N_2O) = C_{27}H_{25}O_4N_2$, the salicylic acid ester of quinine, containing 73.1 per cent. of quinine.

According to the patent specifications it is obtained by heating a mixture of phenyl salicylate (salol) with anhydrous quinine to 170° to 190° C. (338° to 374° F.) in a vacuum, whereby quinine salicylic acid ester and phenol are formed. The phenol set free is removed by distillation and the residue washed with dilute acetic acid to remove unchanged quinine.

It is a white, crystalline powder, melting at 138° C. (280.4° F.), perfectly tasteless and odorless. It is insoluble in water, soluble in acidulated water and moderately soluble in alcohol and in ether. It forms neutral salts which are tasteless, and acid salts.

Its acid solutions are precipitated by alkalies and the usual alkaloidal reagents. The filtrate obtained after shaking saloquinine with water, does not give a violet color with ferric chloride (absence of free salicylic acid).

It is incompatible with acids.

Actions and Uses.—It is a tasteless substitute for quinine and salicylic acid.

Dosage.—0.5 to 2 Gm. (8 to 30 grains).

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Merck & Co., New York). U. S. patent No. 678,401 (July 16, 1901; expires 1918). U. S. trademark No. 37,373 (salochinin), No. 37,374 (saloquinine).

SALOQUININE SALICYLATE. — Saloquinine salicylate $C_6H_4.OH.COO(C_{20}H_{23}N_2O).C_6H_4OH.COOH = C_{34}H_{34}N_2O_3$, is the salicylate of the salicylic acid ester of quinine.

It is prepared by the addition of salicylic acid to a hot alcoholic solution of salicylic acid ester of quinine (see saloquinine) and collection of the crystals which separate out on cooling.

It is a white, tasteless powder, melting at 182° to 183° C. (359.6° to 361.4° F.), sparingly soluble in water, soluble in benzene, chloroform and hot alcohol.

It is incompatible with alkaline liquids.

Actions and Uses.—It has been recommended in acute rheumatism, neuralgia, tabes, gonorrheal inflammations, etc.

Dosage.—1 Gm. (15 grains).

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York). U. S. patent No. 698,079 (April 22, 1902; expires 1919).

RED GUM—Eucalypti Gummi.—Eucalyptus gum. Eucalyptus Kino.

Red gum is an exudation from the bark of Eucalyptus rostrata, Schlecht, and other species of Eucalyptus.

Red gum occurs in small, dark reddish brown, opaque and more or less dusty pieces which yield a pale red powder. It is usually collected from artificial incisions. When chewed it is tough, and colors the saliva red. Water dissolves 80-90 per cent. Its chief constituent is tannic acid, to the extent of 47 per cent.

Action and Uses.—Red gum is an active astringent. It is used as an astringent in sore throat, diarrhea and in catarrhal affections of various mucous membranes. Largely used in the form of lozenges where an astringent is needed in throat affections.

Dosage.—0.1 to 0.3 Gm. (2 to 5 grains).

SABROMIN — Dibromebehenate of Calcium. — Sabromin, $(C_{21}H_{41}Br_2COO)_2Ca = C_{44}H_{82}O_4Br_4Ca$, is the calcium salt of dibrombehenic acid.

It is prepared from erucic acid by the addition of bromine and transformation of the diobrombehenic acid thus obtained into the calcium salt.

Sabromin is a colorless, odorless and tasteless powder claimed to contain about 29 per cent. bromin and about 3.8 per cent. calcium. It is insoluble in water and alcohol, soluble in ether, acetone, benzol, ligroin and tetrachloride of carbon. On heating on platinum foil it is decomposed with liberation of bromine.

Tests: Sabromin is recognized by its solubilities and the liberation of bromine on heating.

Action and Uses.—Sabromin is converted in the stomach into dibrombehenic acid, a substance which is free from any action on that organ, but which is absorbed from the intestine. Its effect is less rapid than that of the bromides, but more prolonged. It is said to be devoid of the disadvantages of the bromides, such as their unpleasant taste, irritating action on the stomach, and systemic by-effects.

Sabromin is indicated in the same class of cases in which the bromides are useful.

Dosage.—The dose is about the same as that of potassium bromide.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 848,230 (March 26, 1907; expires 1924).

Sabromin Tablets, 8 grains.—Each tablet contains sabromin 0.5 Gm. (8 grains).

SAJODIN—Monoiodobehenate of Calcium.—Sajodin, $(C_{21}H_{42}ICOO)_2Ca = C_{44}H_{84}O_4I_2Ca$, is the calcium salt of monoiodobehenic acid.

It is prepared from erucic acid, $C_{22}H_{42}O_2$, by addition of hydrogen iodide, forming monoiodobehenic acid, $C_{22}H_{43}O_2I$. This is converted into the calcium salt.

Sajodin is a colorless, odorless and tasteless powder, insoluble in water. On heating it generates an abundance of iodine vapor; on exposure to light the superficial portion becomes yellow without material decomposition.

It should contain 26 per cent. of iodine and 4.1 per cent. of calcium.

Actions and Uses.—Although containing a smaller quantity of iodine than potassium iodide, sajodin is claimed to be equally efficient. It is said to have been proven exceptionally free from the unpleasant and deleterious by-effects of the iodides.

It is used for the same purposes as potassium iodide.

Dosage.—1 to 3 Gm. (15 to 45 grains) daily.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany, and Farbwerke vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 848,230 (March 26, 1907; expires 1924). Trademark pending.

Sajodin Tablets, 8 grains. Each tablet contains sajodin 0.52 Gm. (8 grains).

SALOPHEN — Acetylparamidophenol Salicylate.—Acetparamidosalol. — Salophen is 1,4-acetamino-phenyl salicylate, $(C_6H_4.OH.COO).C_6H_4NH.(CH.CO)$, the salicylic acid ester of 1,4-acetaminophenol, $C_6H_4(NHCH_3CO)(OH)$.

It is made by preparing paranitrophenol salicylate by a process similar to that of preparing phenyl salicylate (salol); converting this by means of reducing agents into paramidophenol salicylate, and this into acetylparamidophenol salicylate by the action of acetic acid. This crude salophen so obtained is then purified by crystallization from benzene or alcohol.

It forms small, white, crystalline leaflets or powder, odorless and tasteless, melting at 187° to 188° C. (368.6° to 370.4° F.), and containing 51 per cent. of salicylic acid. It is almost insoluble in cold water, more soluble in warm water, but freely soluble in watery solutions of the alkalies and in alcohol, ether and benzene, but not in petroleum benzin.

If its alkaline solution be boiled it gradually becomes blue; on continuing the boiling the color is discharged, but is again produced on cooling and exposure to air. On addition of ferric chloride to the alkaline solution the violet color characteristic of salicylic acid is produced, but a simple aqueous solution of salophen does not react with ferric chloride and should not be changed by silver nitrate. It forms a colorless solution with concentrated sulphuric acid.

It is incompatible with alkalies, which decompose it.

Actions and Uses.—The actions of salophen resemble those of phenyl salicylate (salol). It is not changed in the stomach, but is broken up in the intestine, liberating salicylic acid and acetylparamidophenol, which, unlike phenol, is not toxic. It acts as an antirheumatic, antipyretic, antiseptic and analgesic. It is said to be useful in rheumatism, gout, typhoid fever, and as an intestinal antiseptic, in diarrhea and dysentery. Externally it has been applied in psoriasis and other itching skin diseases.

Dosage.—0.3 to 1 Gm. (5 to 15 grains), in powder, wafers or capsules. Externally in 10 per cent. ointment.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 492,868 (expired). U. S. trademark 20,759.

SANGUINARINE NITRATE —Sanguinarinæ Nitras.—Sanguinarine nitrate is the nitrate $(C_{20}H_{15}NO_4.HNO_3)$ of the alkaloid sanguinarine, obtained from sanguinaria canadensis and other plants.

Sanguinarine nitrate occurs in orange-yellow crystalline needles or deep-orange colored powder. It is soluble in water and in alcohol.

Action and Uses.—Sanguinarine is a violent poison producing in mammals vomiting, purging, convulsions with loss of reflex activity and cardiac depression. The blood pressure is said to be raised by small doses.

The principal use of sanguinarine nitrate is as a stimulant expectorant in chronic bronchitis and in the later stages of acute bronchitis. It is said to be an emmenagogue and may be used in functional amenorrhea.

Dosage.—0.004 to 0.06 Gm. (1/16 to 1 grain); as an expectorant 0.004 to 0.008 Gm. (1/16 to ⅛ grain); as an emetic 0.015 to 0.06 gm (¼ to 1 grain); average dose 0.015 Gm. (¼ grain) to be given with caution.

SANTYL—Santalolis Salicylas.—Salicylic Ester of Santalol.—Santyl is santalyl salicylate, $C_6H_4OH.COO(C_{15}H_{23}) = C_{22}H_{28}O_3$, the salicylic acid ester of santalol.

According to the German patent the neutral esters of sandalwood oil are produced by heating the oil with the respective acid anhydrides and subsequent purification of the product.

Santyl is a yellowish oil with only a faint balsamic odor and taste; specific gravity, 1.07 at 15° C. (59° F.); it boils under 20 mm. pressure at 121° C. (250° F.) to 126.6° C. (260° F.) with partial decomposition; insoluble in water, but soluble in about 10 parts of alcohol.

It is incompatible with alkalies and with the usual incompatibles of sandalwood oil and of salicylates.

Santyl should possess the physical constants given above. On saponification with alcoholic sodium hydroxide it should yield approximately 40 per cent. of salicylic acid and 60 per cent. of santalol.

Actions and Uses.—It is said that santyl passes the stomach unchanged, but is slowly split up in the intestines into its constituents, santalol and salicylic acid. Santyl is claimed to have the same actions as sandalwood oil, except that because of the slow liberation of santalol, it produces no irritation of the gastrointestinal tract nor of the kidneys and urinary passages, nor any unpleasant odor or eructations.

It is claimed to be useful like santal oil for gonorrheal urethritis.

Dosage.—1.5 Cc. (24 minims) usually given in three capsules of 0.5 Cc. (8 minims) each, three times a day.

Manufactured by Knoll & Co., Ludwigshafen, a. R., Germany (Knoll & Co., New York). German patent No. 173,240. U. S. patent No. 862,858 (Aug. 6, 1907; expires 1924). U. S. trademark No. 61,255.

SECACORNIN.—Ergotin Roche.—Secacornin is a solution of the active principles of ergot in a menstruum consisting of distilled water, glycerin and 7.5 per cent. of alcohol. 1 Cc. of secacornin corresponds to 4 Gm. of ergot U. S. P. and is said to be standardized according to the method of Kehrer (Arch. f. exp. Path. u. Pharm., vol. lviii).

Secacornin is prepared from ergot by removing fat by means of benzin or similar solvent and exhausting by percolation with diluted alcohol. The total percolate is then deprived of its alcohol by distillation in vacuo. The resinous mass which separates after cooling is then carefully drained off and the clear filtrate having been evaporated to the consistency of an extract is mixed with the general vehicle.

Secacornin is a dark brown solution, said to be sterile. It is claimed that it does not deteriorate on keeping.

Secacornin responds to the following identity test: 1.6 Cc. secacornin is mixed with 3.0 Cc. distilled water, and 5 drops of 10 per cent. ammonia water, and shaken out in a separatory funnel with 20.0 Cc. of ether. After complete separation of the two liquids, the aqueous solution is allowed to flow off, the remaining ether washed with 2.0 Cc. distilled water, and the wash-water likewise carefully separated. After this the ethereal solution is filtered into an Erlenmeyer flask, and traces of water removed by the use of as much anhydrous sodium sulphate as can be held on the point of a knife. Following this it is filtered into a small glass dish and cautiously evaporated.

The residue is then dissolved in from 1 to 1½ Cc. ferric-chloride-acetic acid (1 drop of Liq. ferri chloridi with 200 Cc. acetic acid). To this solution is added with a pipette, cautiously and without mixing, in order to form an understratum, 3.0 Cc. pure concentrated sulphuric acid. At the point of contact of the two liquids a characteristic blue to violet ring forms after a time.

Action and Uses.—The same as ergot.

Dosage.—0.5 Cc. (8 minims) are equivalent to 2 Cc. (30 minims) of fluid extract of ergot U. S. P. It may be given by intramuscular injection in doses of 0.5 to 1 Cc. (8 to 15 minims).

Manufactured by F. Hoffmann-LaRoche & Co., Basel, Switzerland (The Hoffmann-LaRoche Chemical Works, New York). Not patented. U. S. trademark No. 58,830.

SERUMS AND VACCINES

The vaccines, viruses and serums constitute one of the most important groups of drugs with which the physician has to deal. Some preparations of this group are specific cures for certain diseases; others are invaluable in prophylaxis and diagnosis. The great importance of exercising some degree of governmental control over these products was recognized by the passage by Congress in 1902, of a law entitled "An Act to Regulate the Sale of Viruses, Serums, Toxins and Analogous Products in the District of Columbia, to Regulate Interstate Traffic in Said Articles, and for Other Purposes." The law provides for the licensing of manufacturers who make these products. In order to obtain such a license it is necessary for an establishment desiring it to request the Surgeon-General of the U. S. Public Health and Marine-Hospital Service to have an inspection made of its laboratories, methods, products, etc. This inspection is made by an officer of that service, and consists in a careful examination of the stables, laboratory facilities, methods, animals, collection of the serum, standardization, and tests for potency, purity and amount of preservation. Samples of the products from licensed manufacturers are bought on the open market and examined at frequent intervals in the Hygienic Laboratory of the Public Health and Marine-Hospital Service. The inspection of the laboratories is repeated at least once a year and if unsanitary conditions are found, or if the products are not what they are claimed, the license is suspended.

Antidiphtheric and antitetanic serums are required to conform strictly to the standards which have been established by the United States Government. There being no established standard for the various other products they are not examined for their therapeutic value in the laboratory, but are tested for the amount of preservative and freedom from bacterial and toxic contaminations. Vaccine virus is examined particularly for its freedom from pathogenic bacteria, especially tetanus, and also for its potency.

The following pages contain a description of the preparations which may be legally sold in interstate commerce in the United States and which have not been found to conflict with the rules of the Council:

Serums and Viruses

SERUM ANTIDIPHTHERICUM AND ANTIDIPHTHERIC GLOBULINS.—Antidiphtheric Serum or Diphtheria Antitoxin is an official preparation; for description see the U. S. Pharmacopeia, 8th decennial revision. The diphtheria antitoxin sold in interstate commerce in the United States and in the District of Columbia is required to conform to the standard established by the United States Public Health and Marine-Hospital Service. Some manufacturers mix serums of different strengths so as to secure a preparation containing approximately a definite number of units per c.c. Most of the firms also market a concentrated diphtheria antitoxin or antidiphtheric globulins prepared by the removal, by precipitation with neutral salts, of most of the constituents of the serum except that fraction of the globulins bearing antitoxic potency.

Inasmuch as the ordinary (not concentrated) serum antidiphthericum is contained in the U. S. P., it is desirable that the term "U. S. P." be used in connection with this product (and only with this one) in order to avoid confusion with the globulin preparations.

The French, German and Spanish Pharmacopeias recognize both liquid and desiccated preparations.

H. M. Alexander & Co., Marietta, Pa.

Diphtheria Antitoxin. Only the antidiphtheric globulin is marketed; the antidiphtheric serum is concentrated and refined in accordance with recent improvements of the Gibson method. Marketed in syringes containing from 500 to 5,000 units.

Burroughs, Wellcome & Co., London, England, and New York City.

Diphtheria Antitoxin Serum. Serums of different values from a number of horses are mixed to yield a definite value (from 450 to 500 units per Cc.), also a high potency serum, 1 Cc. of which contains 1,000 units. Trikresol (0.3 per cent.) is added as a preservative. Marketed in hermetically-sealed vials containing 1,000 to 4,000 (Ehrlich-Behring) units; also a high potency serum containing from 1,000 to 10,000 units.

Cutter Laboratory, Berkeley, Cal.

Diphtheria Antitoxin. Marketed in syringes containing 4,000 units; also in bulbs. Diphtheria antitoxin globulin marketed in syringes containing 1,000 units.

Farbwerke, vorm. Meister, Lucius and Bruening, Hoechst a. M., Germany. (Victor Koechl & Co., New York.)

Diphtheria Antitoxin "Behring;" imported into the United States only upon special order.

Department of Health, City of New York.

Refined and Concentrated Diphtheria Antitoxin (Globulin). The preparation is a solution of the globulins of the blood which are soluble in a saturated sodium chloride solution; this contains most of the antitoxin. Preserved with chloroform. Marketed in syringes containing from 2,000 to 5,000 units, each Cc. containing 800 to 1,500 units. Also in bulk.

Wm. R. Hubbert, Detroit, Mich.

Diphtheric Antitoxin. Marketed only in bulk (usually from 1 to 10 liters).

Lederle Antitoxin Laboratories, New York City. (Schieffelin & Co., New York.)

Diphtheria Antitoxin. Only antidiphtheric globulin is sold; this is marketed in syringes containing from 500 to 10,000 units each; also in vials containing from 1,000 to 5,000 units each. The latter are prepared more particularly for the use of Boards of Health.

Memorial Institute for Infectious Diseases, Chicago.

Antidiphtheritic Serum. Most of the antitoxin prepared is concentrated. Marketed in packages of from 1,000 to 5,000 units each, both in syringes ready for use and in bottles.

H. K. Mulford Co., Philadelphia.

Diphtheria Antitoxin, Concentrated (globulin). Prepared from serum antidiphthericum by the removal, by precipitation at 33⅓ per cent. saturation with ammonium sulphate, of the serum albumins *and globulins. The product consists essentially of a soluble* serum globulin freed from inorganic salts by dialysis and redissolved in physiological salt solution. Preserved with not more than ¼ per cent. trikresol or not more than 1/10 to 1 per cent. chloroform. Marketed *in syringes containing from 1,000 to 5,000 units.*

National Vaccine and Antitoxin Institute, Washington, D. C.

Diphtheria Antitoxin, Concentrated; prepared according to Gibson's method. Preserved with chloroform. Marketed in syringes containing from 500 to 6,000 units.

Parke, Davis & Co., Detroit, Mich.

Antidiphtheric Serum, U. S. P.; preserved with 0.4 per cent. trikresol; marketed in piston syringe containers of from 500 to 5,000 units each.

Antidiphtheric Globulins. Marketed as above.

Antidiphtheric Globulins (dry). Marketed in packages of 3,000 units each. The dry powder is readily soluble in water and will keep indefinitely.

Frederick Stearns & Co., Detroit, Mich.

Diphtheric Antitoxin, U. S. P. Preserved with 0.4 per cent. trikresol. Marketed in syringe containers holding from 1,000 to 4,000 units.

Concentrated Diphtheric Antitoxin. Prepared by the Gibson process; preserved with chloroform (2.4 minims per fluid ounce). Marketed as above; also in syringes containing 5,000 units.

ANTIDYSENTERIC SERUM.—

H. K. Mulford Co., Philadelphia, Pa.

Antidysenteric Serum. The blood serum of horses immunized against the Shiga bacillus. Recommended in dysentery and summer diarrheas where the bacillus of Shiga is an etiologic factor. Marketed in syringes containing 10 Cc. Dose 10 to 40 Cc. every *four to eight hours;* to be injected hypodermically.

ANTIGONOCOCCIC SERUM.—Favorable results have been reported from the use of antigonococcic serum in the treatment of chronic complications of gonorrhea involving serous cavities, especially the joints. The results in the case of the chronic stages and sequels of gonorrhea involving the genitourinary tract seem to be less favorable while it seems to have still less value in acute gonorrheal affections.

Parke, Davis & Co., Detroit, Mich.

Antigonococcic Serum, prepared from the blood of rams immunized against both dead and living cultures of virulent gonococci according to the method of Rogers and Torrey[1]. Marketed in bulbs

Dosage. Two Cc. subcutaneously, to be repeated in 1 to 4 days.

ANTIMENINGOCOCCUS SERUM.—

Farbwerke, vorm. Meister, Lucius und Bruening, Hoechst a. M., Germany. (Victor Koechl & Co., New York..

Meningococcus Serum "Hoechst." A serum prepared by the immunization of horses with virulent cultures of diplococcus intracellularis or its products *according to* Ruppel's method. Recommended as a *diagnostic agent for* distinguishing (by the agglutination test) the meningococcus from other diplococci and as a prophylactic and curative agent. It is injected subcutaneously or intralumbarly or in the dry form may be used as a dusting powder applied to the nasopharyngeal space or tonsils. Marketed in powder form mixed with 49.5 per cent. milk sugar and 0.5 per *cent. alumnol, for use as a dusting powder;* also in the dried form to be dissolved in 10 parts of water and injected subcutaneously or intralumbarly; also in the liquid form, preserved with 0.5 per cent. phenol (for agglutination tests).

Dose. 2.5 Gm. of the dried serum, dissolved in 25 Cc. water, subcutaneously to be followed, after lumbar puncture, by 10 *to* 15 Cc. or more, intralumbarly. In severe cases much larger amounts are recommended. 1 Gm. as a protective dose.

H. K. Mulford Co., Philadelphia.

Antimeningitis Serum. A serum prepared from the blood of *horses immunized to the meningococcus of* Weichselbaum (Diplococcus intracellularis), according to the method of Flexner (inoculation of autolyzed cultures followed by living organisms).

It is useful for the treatment of epidemic cerebrospinal meningitis, due to the meningococcus.

Dose. 15 to 30 Cc. (4 to 8 fluidrams) *given* by intraspinal injection. For young infants, 10 Cc. (2½ fluidrams). The serum is marketed in aseptic glass syringes with sterilized needle.

ANTIPNEUMOCOCCUS SERUM.—Antipneumococcus serum is the blood serum of horses immunized against pneumococci. Frequently both dead and living pneumococci are used.

Use.—It has been said *to be useful in the treatment of pneumonia* when injected subcutaneously. Hektoen, Weaver and Tunnicliff have *recently* examined the serums of this class found on the American market. They summarize their views as follows: "In the *antipneumococcus serums it was* impossible to demonstrate antibodies for pneumococci by any method employed."

"It is our belief that the claims for the usefulness of anti*streptococcus and antipneumococcus serums rest on* impressions from results in clinical cases in man, and have in most cases no foundation whatsoever in experimental tests."

H. K. Mulford Co., Philadelphia.

Antipneumococcic Serum, stated to be prepared by immunizing horses with both *dead and living pneumococci.* Marketed in syringes containing 20 Cc. Dose: 20 to 100 Cc.

Frederick Stearns & Co., Detroit, Mich.

Pneumolytic Serum, stated to be a composite polyvalent serum prepared by injecting horses with virulent pneumococci from various sources. The horses are first immunized with diphtheria toxin. *Marketed in syringes containing 20 Cc. Dose:* 10 to 20 Cc., to be repeated in 12 to 24 hours.

ANTISTAPHYLOCOCCUS SERUM.—

Burroughs, Wellcome & Co., London, England, and New York.

Antistaphylococcus Serum is stated to be obtained from horses injected with killed cultures of staphylococcus pyogenes aureus, albus and citreus. Preserved with trikresol. Marketed in vials containing 25 to 50 Cc. Recommended in the treatment of various staphylococcus infections.

ANTISTREPTOCOCCUS SERUM.—Antistreptococcus serums are prepared by immunizing horses with virulent cultures of streptococci. Most manufacturers employ several strains of streptococci, thus obtaining polyvalent serums. In some cases humanized strains of streptococci are used; in others, cultures, the virulence of which has been much increased by passage through animals. In a few cases both human and animal strains are employed. Some manufacturers employ horses immunized against diphtheria, making the doubtful claim that such serum is especially active in stimulating leucocytosis and phagocytosis.

Actions and Uses.—Antistreptococcus serum has been claimed to be useful in the *treatment* of streptococcus infections such as erysipelas, scarlet fever, puerperal septicemia, tuberculosis *(mixed infection), etc. It has* also been used as a prophylactic prior to surgical operations, after labor, in scarlet fever epidemics, etc. Its value is doubtful.

Hektoen, Weaver and Tunnicliff recently examined the preparations found on the American market; in a preliminary report (1) they state: "Streptococcus opsonins could not be demonstrated in any of the serums tested, and activation by fresh serums was not accomplished to any significant degree. When *they* were *injected into rabbits,* increase in streptococcus opsonins could not be demonstrated in the animals' serums in any notable degree, except in some instances. Attempts to obtain protective and curative effects from the injection of antistreptococcus serums in rabbits, guinea pigs, and in a more limited scale in mice, met failure. The serums often seemed to reduce the natural resistance and to hasten death."

---

[1] The Journal A. M. A., Sept. 14, 1907, xlix, 918.

containing 2 Cc. each.

"It is our belief that the claims for the usefulness of antistreptococcus and antipneumococcus serums rest on impressions from results in clinical cases in man, and have in most cases no foundation whatsoever in experimental tests."

Antistreptococcus serum (liquid and desiccated) is recognized by the French pharmacopeia.

Burroughs, Wellcome & Co., London, England, and New York.

Polyvalent Antistreptococcus Serum is stated to be obtained from horses injected with killed cultures of a number of strains of cases of erysipelas, scarlet fever, puerperal fever, rheumatism, septicemia, angina, pneumonia and ulcerative endocarditis.

Antistreptococcus Serum (Erysipelas) is stated to be obtained from horses injected with killed cultures of a number of strains of streptococci obtained from cases of erysipelas.

Antistreptococcus Serum (Rheumatism) obtained from horses injected with killed cultures of a number of strains of streptococci obtained from cases of rheumatism.

Antistreptococcus Serum (Scarlatina) obtained from horses injected with killed cultures of a number of strains of streptococci obtained from cases of scarlet fever.

Antistreptococcus Serum (Puerperal Fever) obtained from horses injected with killed cultures of a number of strains of streptococci obtained from cases of puerperal fever.

All of the above are prepared with trikresol and are marketed in hermetically-sealed vials containing in most cases 25 to 50 Cc.

Cutter Laboratory, Berkeley, Cal.

Polyvalent Streptococcic Serum, stated to be prepared by the injection of many strains of living humanized cultures of streptococci into horses immunized with diphtheria toxin. Marketed in piston syringe containers, each containing 10 Cc. of serum.

Chemische Fabrik auf Actien (vorm. E. Schering), Berlin, Germany. (Schering & Glatz, New York.)

Aronson's Antistreptococcus Serum, stated to be a polyvalent serum obtained by inoculating horses with streptococci the virulence of which has been highly exalted by animal passage and with various humanized strains of streptococci. Preserved with 0.4 per cent. trikresol. Dose: 20 to 100 Cc., according to the severity of the case and the age of the patient.

Farbwerke, vorm. Meister, Lucius and Bruening, Hoechst a. M., Germany. (Victor Koechl & Co., New York.

Antistreptococcic Serum, Hoechst, stated to be a polyvalent serum, prepared by immunizing horses against streptococcus cultures of the most varied origin and with highly virulent passage cultures according to the method of Meyer and Ruppel. Contains no artificial preservatives. Dosage: 1 to 10 Cc. for immunization. 2 to 25 Cc. for single curative dose. 3 to 50 Cc. for double curative dose.

Lederle Antitoxin Laboratories, New York City. (Schieffelin & Co., New York.)

Antistreptococcic Serum Polyvalent; marketed in 10 Cc. syringes. Dose: as a prophylactic, 10 Cc.; curative, 20 to 100 Cc.

H. K. Mulford Co., Philadelphia.

Antistreptococcic Serum, stated to be the serum of horses which have been treated with streptococci of various strains. Marketed in 10 Cc. syringes. Dose: 20 to 80 Cc.

Parke, Davis & Co., Detroit, Mich.

Antistreptococcic Serum, stated to be a polyvalent serum; prepared by immunizing horses with killed cultures of streptococci; the latter are obtained from various human streptococcus infections and certain pathologic conditions common to animals. Preserved with trikresol. Marketed in 10 Cc. piston syringe containers, also in bulbs containing 10 Cc. each.

Frederick Stearns & Co., Detroit, Mich.

Streptolytic Serum, stated to be a composite and polyvalent serum; composite because it contains diphtheric antitoxin in addition to the streptococcus antibodies. Marketed in 10 Cc. syringes some of which have attachments for subcutaneous injection, others for rectal injection.

ANTITUBERCLE SERUM.—

Parke, Davis & Co., Detroit, Mich.

Antitubercle Serum. A serum prepared by treating horses for several months with the toxic products of the tubercle germs. Stated to be an experimental remedy claimed by some to give favorable results in tuberculosis. Marketed in 1, 2 and 4 Cc. bulbs and in 1 ounce bottles. Dose: 1 to 4 Cc. daily hypodermically.

ANTITYPHOID SERUM.—Antityphoid serum is a serum obtained from horses which have been injected with killed cultures of bacillus typhosus.

Actions and Uses.—Antityphoid serum has been employed in the treatment of typhoid fever, but the evidence as to its value is conflicting.

Burroughs, Wellcome & Co., London, England, and New York.

Anti-typhoid Serum is stated to be obtained from horses injected with killed cultures of Bacillus typhosus. Marketed in hermetically-sealed vials containing 25 to 50 Cc.

TETANUS ANTITOXIN.—(Antitetanic Serum and Antitetanic Globulin).—Antitetanic Serum is the blood serum of horses immunized to the toxin of the tetanus bacillus. It is marketed in both liquid and dry forms. Some manufacturers prepare an Antitetanic Globulin; this contains a solution of the globulins of the blood, which are soluble in a saturated sodium chloride solution, together with the antitoxin, and contains the latter in concentrated form.

The antitetanic serum sold in interstate commerce in the United States should conform to the standard established by the United States Public Health and Marine-Hospital Service. This standard is defined as follows (Treasury Department Circular No. 61, Oct. 25, 1907; Bulletin 43, Hygienic Laboratory): "The immunity unit for measuring the strength of tetanus antitoxin shall be ten times the least quantity of antitetanic serum necessary to save the life of a 350-gram guinea pig for ninety-six hours against the official test dose of a standard toxin furnished by the Hygienic Laboratory of the Public Health and Marine-Hospital Service."

Uses.—Antitetanic serum is used both as a prophylactic and a curative agent in tetanus. The dried product may be used as a dusting powder.

Dose.—Immunizing, 1,500 units; in tetanus, 3,000 to 20,000 units every four to eight hours.

Serum Antitetanicum is official in the Belgian, French and Swiss Pharmacopeias. Both liquid and desiccated preparations are recognized by the French Pharmacopeia.

Department of Health, City of New York.

Antitetanic Globulin. Preserved with chloroform. Marketed in vials containing 1,500 to 5,000 units.

Lederle Antitoxin Laboratories, New York City. (Schieffelin & Co., New York.)

Only the concentrated antitoxin (globulin) is marketed; this is offered in syringes containing from 1,500 to 5,000 units each.

H. K. Mulford Co., Philadelphia, Pa.

Tetanus Antitoxin, marketed in syringes containing 1,500 units.

Parke, Davis & Co., Detroit, Mich.

Antitetanic Serum, marketed as follows:

1. In piston containers, 1,500 units.
2. In bulbs containing 1,500 units.
3. Dry.
4. Antitetanic Dusting Powder; the dried serum mixed with a small quantity of chloretone (chlorbutanol).

VACCINE VIRUS.—Vaccine virus is the material obtained from the skin eruptions of calves having vaccinia. The "pulp" is ground and mixed with varying percentages of glycerin. The latter has a certain degree of antiseptic action. It is usually marketed in capillary tubes or as glycerinated points. The serums which exude after the removal of the crusts have been used by some manufacturers for the preparation of "dry lymph points." These are generally regarded as unsatisfactory and the new federal regulations forbid interstate traffic in them after Jan. 1, 1910.

Some firms test the activity of their products on the cornea of rabbits and on calves.

Vaccine virus is official in the Belgian Pharmacopeia under the name "Vaccinum"; in the Swiss as "Virus Vaccinum."

H. M. Alexander & Co., Marietta, Pa.

Marketed as "glycerinated lymph" in capillary tubes; also as "glycerinated vaccine points" and as "dry points."

Cutter Laboratory, Berkeley, Cal.

Marketed in two forms; ivory points (dry) and in capillary tubes.

Lederle Antitoxin Laboratories, New York City. (Schieffelin & Co., New York.)

Glycerinated Vaccine Virus: (a) in glass capillary tubes and in bulk (for 10, 20 or 50 vaccinations); (b) upon Lederle's Protected Ivory Points; the latter are contained in capsule-like glass tubes which do not require breaking.

H. K. Mulford Co., Philadelphia.

Glycerinated Vaccine Lymph, in sealed capillary tubes. Glycerinated Glass Vaccine Points; glycerinated lymph on sterile glass points.

National Vaccine and Antitoxin Institute, Washington, D. C.

Glycerinated Vaccine Virus marketed in capillary tubes; Glycerinated Vaccine Virus on Ivory Points; special capsule.

Parke, Davis & Co., Detroit, Mich.

Glycerinated Vaccine: (a) in capillary tubes, (b) on ivory points. The points are contained in sealed glass tubes provided with Lee's breakable ring so that they may be opened without difficulty.

BACTERIAL VACCINES

Bacterial vaccines (cf. also tuberculin) are suspensions of the killed bacteria in physiologic salt solution; phenol (0.5 per cent.) is usually added as a preservative. Being suspensions, there is a tendency for the bacteria to settle on standing; hence the vial should be shaken before the syringe is filled and the latter should be shaken before injecting.

Pharmacopeial Preparation.—The French Pharmacopeia contains a *"Vaccin antipesteux,"* consisting of a suspension of killed plague bacilli and a *"Vaccin antipesteux sensibilisé,"* prepared by treating killed plague bacilli with antiplague serum. (Antiplague Serum is also official in the French Pharmacopeia.)

Actions and Uses.—The use of many of these vaccines is in the experimental stage. Bacterial vaccines are often prepared from cultures obtained from the individual to be treated (autogenous vaccines); these usually give the best results. *In fact some authors maintain that "stock" vaccines should be used only when it is impracticable to secure the autogenous agent.*

Bacterial vaccines are used to aid the production of an active immunity. Great care and skill are necessary for their proper use and *no* definite statements as to dosage, etc., can be given; the physician must be guided by the condition of the patient and the manner in which the latter reacts to the treatment.

The following were licensed to manufacture and sell in interstate commerce products of this character prior to July 15, 1909. (Cf. also Tuberculin).

Burroughs Wellcome & Co., London, England and New York City.
Lederle Antitoxin Laboratories, New York City.
H. K. Mulford Co., Philadelphia, Pa.
National Vaccine and Antitoxin Institute, Washington, D. C.
Parke, Davis & Co., Detroit, Mich.
Swiss Serum and Vaccine Institute, Berne, Switzerland.

The following products have been submitted to the Council:

Some of the licensed firms do not market stock vaccines, but prepare them only from cultures from patients.

ACNE VACCINE.—A vaccine prepared from acne bacilli (Bacillus acnes). Said to be useful in the milder forms of acne.

H. K. Mulford Co., Philadelphia.

Acne-Bacterin. This product is marketed in four syringes containing respectively 25 million, 50 million, 100 million and 200 million killed acne bacilli, sold in a package or as separate syringes.

Dose. Initially 5 to 25 millions.

BACILLUS COLI VACCINE.—Bacillus Coli Vaccine seems to cause distinct improvement in certain infections of the urinary tract, due to the colon bacillus. Pain and frequency of micturition are said to be quickly relieved, but complete elimination of the bacteria is stated to be rare. It has also been used in subacute and chronic appendicitis and in gall bladder fistulas where there was an infection with the colon bacillus.

H. K. Mulford Co., Philadelphia.

Coli-Bacterin. Marketed in 1 Cc. vials; each Cc. is said to contain approximately 50,000,000 killed bacilli suspended in normal salt solution.

BACILLUS PYOCYANEUS VACCINE.—This is said to be useful in local infections in which this organism is present. A recent writer states that he has never experienced the slightest beneficial effect either from the autogenous or stock vaccines prepared from this organism, and considers its use illogical.

H. K. Mulford Co., Philadelphia.

Pyocyano-Bacterin. Each Cc. is said to contain about 30,000,000 killed bacilli.

FRIEDLANDER VACCINE.—A vaccine prepared from the Friedlander bacillus. It is said to be useful in infections by the Friedlander bacillus, such as chronic nasal catarrh and chronic gleet.

H. K. Mulford Co., Philadelphia.

Friedlander Bacterin. This product is marketed in packages of four syringes, containing respectively 50 million, 100 million, 200 million and 400 million killed Friedlander bacilli. The single syringes may be obtained separately.

GONOCOCCUS VACCINE.—Gonococcus vaccine has been used with much success in subacute and chronic gonococcus infections involving the prostate, joints, eyes, etc. It has been stated that the strains of the gonococcus are not so diversified as are those of many other organisms and that therefore better results may be expected from stock vaccines of this organism than in many other cases.

Cutter Laboratory, Berkeley, Cal.

Gonococcic Vaccine. Marketed in 1 Cc. vials; each Cc. containing about 50,000,000 cocci suspended in physiological salt solution with 0.4 per cent. trikresol.

H. K. Mulford Co., Philadelphia.

Neisser Bacterin. Each Cc. is said to contain approximately 50,000,000 killed gonococci; preserved by 0.5 per cent. phenol.

National Vaccine and Antitoxin Institute, Washington, D. C.

Gonococcic Vaccine. Marketed in syringes each said to contain 2,000,000 to 50,000,000 bacteria; sterilized by heat.

Parke, Davis & Co., Detroit, Mich.

Gonococcus Vaccine. P., D. & Co. Marketed in bulbs each said to contain 20,000,000 bacteria; sterilized by heat.

MICROCOCCUS NEOFORMANS VACCINE.—Micrococcus neoformans vaccine is claimed to be beneficial in ulcerated tumors in which this organism occurs as a secondary infection.

H. K. Mulford Co., Philadelphia.

Neoformans-Bacterin. Each Cc. is said to contain approximately 50,000,000 killed neoformans micrococci.

PNEUMOCOCCUS VACCINE.—Pneumococcus vaccine has been claimed to be useful in pneumococcic infections. In laboratory experiments it was found inert so far as indicated by any change in the opsonic index when injected into rabbits.

H. K. Mulford Co., Philadelphia.

Pneumo-Bacterin. Each Cc. is said to contain about 50,000,000 killed pneumococci.

STAPHYLOCOCCUS VACCINES.—These have been used with much success in localized surface infections such as acne, acute boils, carbuncles and septic wounds, in multiple subcutaneous abscesses, sinuses, chronic osteomyelitis, etc. The best results are obtained with autogenous vaccines. Laboratory experiments have also shown that these vaccines possess distinct antigenic properties when tested by infections in rabbits with subsequent opsonin determinations.

Cutter Laboratory, Berkeley, Cal.

Staphylococcus Vaccine. Each Cc. contains about 500,000,000 cocci preserved with 0.4 per cent. trikresol.

H. K. Mulford Co., Philadelphia.

Four varieties of vaccine are offered:

1. *Staphylo-Albus Bacterin.* From staphylococcus pyogenes albus.
2. *Staphylo-Aureus Bacterin.* From Staphylococcus pyogenes aureus.
3. *Staphylo-Bacterin.* Containing a mixed culture of staphylococcus albus, aureus, and citreus.
4. *Staphylo-Acne-Bacterin.* A mixed vaccine prepared from cultures of staphylococcus albus, aureus, and citreus with bacillus acnes.

All the above are marketed in packages of four syringes containing respectively 250 million, 500 million, 1 billion and 2 billion [illegible] The syringes of staphylo-acne bacterin contain [illegible] 25 million, 50 million, 100 million and 200 [illegible] single syringes may be obtained separately.

Parke, Davis & Co., Detroit, Mich.

Four forms of vaccines are offered.
1. From staphylococcus pyogenes albus.
2. From staphylococcus pyogenes aureus.
3. From staphylococcus pyogenes citreus.
4. From the three preceding combined.
Each Cc. contains about 400,000,000 bacteria.

STREPTOCOCCUS VACCINE.—Recommended in various infections by streptococci (scarlet fever, puerperal septicemia, erysipelas, etc.).

H. K. Mulford Co., Philadelphia.

Strepto-bacterin. Each Cc. contains about 50,000,000 killed streptococci.

Parke, Davis & Co., Detroit, Mich.

Streptococcus Vaccine. Each Cc. contains about 40,000,000 streptococci pyogenes.

TYPHOID VACCINE.—Inoculations with typhoid vaccines have been practiced extensively in various armies; the results, both as regards the morbidity and the mortality from typhoid fever seem to have been distinctly favorable. Such inoculations have been recommended in institutions where many of the personnel are not infrequently exposed to typhoid infection and in communities threatened with or affected by typhoid epidemics. It has been suggested that typhoid vaccines may be of value in the treatment of typhoid carriers.

H. K. Mulford Co., Philadelphia.

Typho-bacterin. Each Cc. contains about 50,000,000 killed typhoid bacilli.

TUBERCULIN PREPARATIONS

Tuberculins represent the toxins of the tubercle bacillus. They may be in the form of a filtered extract of the bacilli or may be composed of the pulverized insoluble substance of the bacilli themselves. In the latter, or emulsified form, tuberculin is known as tubercle vaccine, and might be classed with the "Bacterial Vaccines" (which see). Tuberculins are therefore of two general classes:

1. Those prepared from the germ-free culture media, and containing for the most part only soluble products of the bacillus. This class includes Tuberculin "old" (or Tuberculin Koch) and Tuberculin Denys (Bouillon Filtré).

2. Those which contain the greater part of the germ body itself; they include the new tuberculins of Koch ("T. R." and the "New Tuberculin Koch [Bacillus emulsion]").

OLD TUBERCULIN, "O. T." (Tuberculin Originale, "T. O."; Tuberculin Koch).

Old Tuberculin is prepared by evaporating a 6 to 8 weeks' bouillon culture of tubercle bacilli at boiling temperature to 1/10 of its volume and filtration through clay or porcelain. A clear, syrupy, amber colored fluid; containing about 50 per cent. glycerin[1]. Frequently marketed in "serial dilutions" by which the doses may be gradually increased.

TUBERCULIN "DENYS" ("B. F."; Bouillon Filtrate; Bouillon Filtré, Denys).

This is the bouillon from cultures on which tubercle bacilli of the human type have grown to maturity (5 to 6 weeks) freed from germs by filtration through porcelain.

"NEW TUBERCULIN"—"T. R."—New Tuberculin represents a portion of the tubercle bacillus.

It is prepared as follows: A suspension of ground virulent tubercle bacilli is centrifugalized; the upper layer, consisting of extractives and fatty substances mixed with bacilli, is removed while other bacilli and fragments are thrown to the bottom. The sediment is again ground and centrifugalized; the process is repeated until almost no sediment remains. The second and supernatant liquids are united and to them glycerin, 20 per cent., and a little formaldehyde in solution are added; this emulsion is the "T. R." Each Cc. represents the residue from approximately 10 mg. dry originally virulent tubercle bacilli (human).

NEW TUBERCULIN, KOCH, BACILLI EMULSION ("B. E."). This represents the entire bacilli whether soluble or insoluble.

The germs are simply crushed and pulverized and mixed with equal parts of water and glycerin. The suspension contains 5 mg. dry, originally virulent, tubercle bacilli (human).

Action and Uses.—The different modifications and preparations of tuberculin are practically identical in their physiologic effects. They vary chiefly in a quantitative way and in absorbability. They are used both for diagnostic and therapeutic purposes:

Diagnostic Use.—"Tuberculin depends for its diagnostic value on a special sensitiveness acquired by the tissues after a tuberculous infection. This sensitiveness is manifested by an inflammatory response when tuberculin is brought in contact with the skin or mucous membrane."[1] The original tuberculin of Koch is considered the most satisfactory preparation for diagnosis but other filtered extracts are suitable. There are four principal methods of applying the test: 1. The Cutaneous Test (von Pirquet); 2. The Inunction Test (Moro); 3. The Conjunctival Test (Wolff-Eisner, Calmette); 4. The Subcutaneous Test. The proper performance and correct interpretation of these tests require much knowledge and experience. Some of them, notably the conjunctival and subcutaneous tests, may, under certain circumstances and in the hands of inexperienced or careless persons, do much harm.

Use in Therapeutics.—The successful employment of tuberculin in therapeutics depends upon a thorough knowledge of the disease and the individual patient; in many cases its use may do much harm. Baldwin[2] states the general principle involved as follows:

"The therapeutic use of tuberculin may have two fairly definite objects in view: One is to diminish the sensitiveness to the toxin—i. e., to itself—the other is to create intermittent local reactions and thus to stimulate the disease focus to heal or become absorbed. The possibility of the production of a recognizable immunity to the disease thus far by any form of tuberculin treatment is open to question. A certain degree of resistance is indirectly accomplished when sensitiveness to tuberculin is decreased to a marked degree, accompanied by constitutional improvement. Such specific resistance as can be obtained by tuberculin is gradually lost after the treatment is discontinued, so that statements that patients can be made 'immune' are unjustified."

As regards the choice of tuberculin and the method of administration Baldwin says:

"For therapeutic use the choice chiefly lies between the solutions and emulsions or vaccines. Opinions are too variant to permit the formulation of rules. In general the dosage is more controllable with solutions, and reactions are less frequent from emulsions." "Owing to the uncertain absorption of emulsions, reactions may ensue unexpectedly if the dose is increased greatly. The solutions are therefore safer for tuberculin immunization until some accurate standards for determining the dosage shall be made. The dosage is at present empirical; each individual case must be an experiment, and the symptoms carefully observed before each dose. The subcutaneous injection is the only satisfactory method for the administration of tuberculin. Tuberculin pills or capsules for stomach ingestion and suppositories per rectum are too uncertain of absorption to warrant any recommendation. Inunctions of tuberculin have a possible field in treatment of skin tuberculosis; otherwise they are also impracticable."

Pharmacopeial Preparations.—Koch's "old tuberculin" is official in the German Pharmacopeia under the name "Tuberkulinum-Kochi, Tuberkulin"; in the Belgian under the name "Tuberculinum"; in the Swiss under the name "Tuberkulinum Concentratum"; and in the French under the name "Tuberculine Brute." The French and Swiss Pharmacopeias contain also diluted tuberculin ("Tuberkulinum Normale Dilutum" of the Swiss, "Tuberculine Diluée" of the French, Pharmacopeia), prepared by diluting 1 Cc. of the concentrated tuberculin with 10 Cc. of 0.5 per cent. phenol. The French Pharmacopeia contains also a "Tuberculine Solide Purifiée" prepared by precipitating the "Tuberculine Brute" with ten times its volume of 80 per cent. alcohol, washing the precipitate with ether and drying *in vacuo*. For use 0.01 Gm. of this is dissolved in 100 Gm. distilled water.

TUBERCULOSIS SERUM VACCINE.—An emulsion of human tubercle bacilli, sensitized by the application of tuberculosis serum.

The production of sensitized tubercle bacilli, or bacilli which are capable of complement fixation, is accomplished with the assistance of an efficient tuberculosis-immune serum, which has a considerable content of specific amboceptor antituberculin. The content of this serum in specific amboceptor is ascertained according to the method of complement fixation. Besides antituberculin, this serum contains agglutinating, precipitating and bacteriotrope immune bodies.

Emulsions of sensitized tubercle bacilli are prepared as follows: Human tubercle bacilli, after having been thoroughly washed and briskly dried, are mixed with fresh tuberculosis serum, the quantity of which is calculated from the determination of the immunity bodies. This mixture is left for several days in the incubator, at a temperature of 37° C., and is then shaken in an apparatus, with glass beads, until intact tubercle bacilli are no longer demonstrable in the removed sample. The broken-up masses of bacilli are then separated from the serum, through centrifugalization, washed with physiologic salt solution, and finally worked into fine emulsions, with 40 per cent. glycerin water, to which has been added phenol 0.5 per cent. The contents of this emulsion in bacillary substance amounts to 0.005 Gm. in 1 Cc. The original emulsions and dilutions are to all intents and purposes permanently durable, provided they are kept in a cool place, not exposed to freezing, and protected from the light.

---

[1] Some firms add trikresol to their preparations of this tuberculin; the necessity or advisability of this is considered questionable if the glycerin is of the proper strength. It is stated that trikresol will, in the course of time, weaken the tuberculin.

[1] Baldwin: THE JOURNAL A. M. A., 1910, liv, 260.
[2] Baldwin: THE JOURNAL A. M. A., 1910, liv, 260.

Actions and Uses.—It is claimed that this emulsion contains specific immune bodies which are non-poisonous for healthy and tuberculous subjects, but are capable of exerting a remarkable effect on tuberculous processes.

Preparations[1]*:*

The use of ready made "serial dilutions" as a routine practice is not to be commended. Such solutions deteriorate rapidly, especially in the presence of phenol or trikresol and the rate of such deterioration may not be the same in different dilutions; competent authorities think it desirable to limit the use of dilutions to one month or even less in the case of soluble tuberculins. Some firms state the date of manufacture on the labels; it is desirable that this should de done in all cases. Sufficient precautions are often not given as to the care necessary in passing from a weak to a stronger solution.

The dangers from the use of tuberculin in the eye are not sufficiently emphasized by some firms.

The "conclusions" which some manufacturers state may be drawn from a "positive reaction" seem to the Council to be in some cases stated too dogmatically.

H. M. Alexander & Co., Marietta, Pa.

Original Tuberculin "O. T." (Koch); marketed in 1 and 3 Cc. vials.

Tuberculin.—Bouillon Filtrate "B. F." (*Human*). 1 and 3 Cc. vials.

Tuberculin Residue. T. R. (Human) (Koch).

Bacillin Emulsion "B. E." (*Human*).

Dixon's Tubercle Bacilli Extract (See "Fluid of Dixon," Medical News, Jan. 17, 1891). An extract of tubercle bacilli dissolved in normal saline solution. Marketed in syringes containing the extract from 1 mg. bacilli. The standard therapeutic dose is a weekly injection of the contents of 1 syringe, to be reduced in amount and frequency if the patient shows signs of reaction.

Dixon's Suspension of Dead Tubercle Bacilli (See "Possibility of Establishing Tolerance for Tubercle Bacilli," Medical News, Oct. 19, 1889). A suspension of dead tubercle bacilli in physiologic salt solution which have been decreased by prolonged treatment with alcohol and ether. Marketed in syringes containing 0.001 mg. bacilli, which is the standard therapeutic dose (cf. preceding).

Tuberculin for the Cutaneous Test (von Pirquet). A solution of *tuberculin original* in capillary tubes. Solutions of two strengths, one for children and one for adults, are prepared.

Tuberculin Ointment Capsules (for the Moro Test). Consists of equal parts by weight of Koch's Old Tuberculin and anhydrous wool fat. Marketed in capsules.

Tuberculin for the Ophthalmic Test. Tuberculin Precipitatum, "T. P." Prepared by precipitation with 95 per cent. alcohol from Koch's Old Tuberculin. Marketed in tubes in solutions of two strengths (0.5 per cent. and 1 per cent.).

Tuberculins for the Detre Differential Diagnostic Test. Three capillary tubes: 1. Tuberculin Original, "T. O." 2. Bouillon Filtrate, "B. F." (Human). 3. Bouillon Filtrate, "B. F." (Bovine).

Cutter Laboratory, Berkeley, Cal.

Tuberculin "Old," Koch; Concentrated; in 1 Cc. vials and preserved with trikresol; for use in solutions only. Also in serial dilutions; the latter in packages containing 5 bottles each holding about 8 Cc., ranging from 0.01 to 100 mg. per Cc.

Deny's Bouillon Filtrate; in 1 Cc. vials; preserved with trikresol; for use in dilutions only. Also in serial dilutions.

Tubertulin, Koch (*concentrated*).—For the *cutaneous reaction;* in capillary pipettes.

Tuberculin, Purified; 1 per cent. solution, for the ophthalmic reaction.

Farbwerke vorm. Meister, Lucius and Bruening, Hoechst a. M., Germany. (Victor Koechl & Co., New York.)

Tuberculin "Koch" (old). Marketed in vials containing 1 Cc., 5 Cc. or 50 Cc.

New Tuberculin "Koch" (T. R.). Marketed in vials containing 1 Cc. and 5 Cc.

Koch's Bacilli Emulsion. Marketed in vials containing 1 Cc. and 5 Cc.

Tuberculosis Diagnostic "Hoechst." Dried tuberculin free from glycerin, prepared from Tuberculin Koch (old Tuberculin). To be used in 0.1 per cent. solutions for the tuberculo-ophthalmic reaction.

Tuberculosis Diagnostic "Hoechst" Dry in Tubes. Each tube contains 0.005 Gm. (1/10 grain).

Dosage. The contents of a tube are dissolved in 5 Cc. of cold sterile water.

Tuberculosis Diagnostic "Hoechst" 0.1 per cent. solution.

Dosage. The contents of the tube are ready for use.

Tuberculin T. O. A. Original Tuberculin T. O. A. This preparation is a bouillon filtrate. For preparation see Tuberculin "Deny's," Supplied in bottles containing 1 Cc. and 5 Cc.

Vacuum Tuberculin. Tuberculin T. O. A. reduced to 1/10 of its volume in a partial vacuum at a low temperature.

Actions and Uses. It is intended solely for the treatment of patients who exhibit too violent reactions to Old Tuberculin, to Tuberculin T. R. and to Tuberculin Bacilli Emulsion.

Vacuum Tuberculin is marketed in glass bottles containing 1 Cc. and 5 Cc.

Dry Dead Tubercle Germs. For use in making the bacillary emulsion for the tuberculo-opsonic test.

Bovine Tuberculin. Tuberculin corresponding to Tuberculin "Koch" Old but prepared from bovine bacilli. Marketed in bottles containing 1 Cc. or 5 Cc.

Bovine Bacilli Emulsion. Corresponding to Koch's Bacilli Emulsion but prepared from bovine bacilli. In original bottles containing 1 Cc. and 5 Cc.

Bovine Tuberculin T. R. C[illegible] berculin T. R. but prepared from bovine bacilli. 1 [illegible] 1 Cc.

Bovine Tuberculin Old. A bouillon filtrate from bovine bacilli. Indications similar to those for Tuberculin T. O. A. Supplied in glass bottles containing 1 Cc. and 5 Cc.

Vacuum Bovine Tuberculin. A tuberculin prepared from bovine bacilli by the process for vacuum tuberculin. The advantage of the vacuum preparations is only in their better keeping qualities. Vacuum bovine tuberculin is supplied in glass bottles containing 1 Cc. and 5 Cc.

Polygenous Tubercle Bacilli Emulsion. A bacilli emulsion prepared from eight different cultures of tubercle bacilli which differ as much as possible from each other.

Dead Bovine Tubercle Bacilli. Supplied in flasks containing 1 Gm. and 5 Gm.

Tuberculin Residue. Tuberculin residue is supplied in the form of a moist paste and a dry preparation in vials of 1 Gm. and 5 Gm. each.

Tuberculosis Serum Vaccine "Hoechst." Emulsions of sensitized tubercle bacilli are supplied in the original concentration, in vials of 1 and 5 Cc. each, and also in serial dilutions.

Dosage. The treatment is begun with 0.1 Cc. of a dilution 1/1,000,000 and the dose gradually increased until 0.5 Cc. of the original emulsions are readily tolerated and the corresponding clinical effects are demonstrable. It should not be used in the presence of cachexia, mixed infection or permanent rise of temperature.

Tuberculin Gesellschaft, St. Petersburg, Russia. (Morgenstern & Co., New York.)

Endotin.—Tuberculinum Purum. Endotin is the purified extract of a filtered culture of human bacilli in 50 per cent. glycerin.

Endotin is prepared exactly as Koch's "Old" tuberculin, but is subsequently treated with alcohol, ether, chloroform and xylol in order to eliminate the deuteroalbumoses present.

Tuberculinum purum is now supplied in a carton of 4 series which are intended to represent a course of tuberculin treatment. Each series consists of 7 ampuls.

H. K. Mulford Co., Philadelphia.

Tuberculin "Old" (O. T.). Marketed in 1 Cc. vials; also in serial dilutions in 5 vials of 8 Cc. each progressing by doses of 2 minims containing 0.001 mg. to 2 minims containing 10 mg.; in rectal suppositories containing from 1 to 500 mg. tuberculin in cacao butter.

Tuberculin, Bouillon Filtrate, Denys. Marketed in 1 Cc. vials; also in serial dilutions.

Tuberculin "R." Marketed both in concentrated form and in serial dilutions.

Bacillin Emulsion "B. F." Marketed in 1 Cc. vials; also in serial dilutions.

Tuberculin Ophthalmic Test Solution. Prepared from the precipitate obtained on treating Tuberculin "Old" with 70 per cent. alcohol; ½ and 1 per cent. solutions in physiological salt solutions are made of the dry precipitate.

Tuberculin Ophthalmic Test Tablets. The precipitate as prepared above; each tablet contains 1 mg. dried tuberculin; to be dissolved in 0.13 Cc. (2 minims) of water.

Tuberculin Ointment. An ointment consisting of 50 per cent. of tuberculin "Old" with an equal part of adeps lanae hydrosus.

Parke, Davis & Co., Detroit, Mich.:

Tuberculin, "Old" (Koch). Marketed in ½ Cc. bulbs.

Tuberculin B. E. (concentrated). Bacillus Emulsion, marketed in bulbs containing 1 mg. of dry tubercle solids per Cc.

Tuberculin B. F.; marketed in 1 Cc. bulbs; contains 0.4 per cent. trikresol.

Tuberculin T. R. Marketed in 1 Cc. bulbs in 2 strengths; one contains 0.001 mg. of tubercle solids per Cc., the other 1 mg. per Cc.

Tuberculin Discs for the Ophthalmic Reaction. Prepared by precipitating concentrated tuberculin with alcohol. Each disc contains 3.3 mg. tuberculin which when dissolved in 0.3 Cc. (5 minims) of water makes a 1 per cent. solution.

Moist Dead Tubercle Germs. For use in making the bacillary emulsion for the tuberculo-opsonic test.

Bacterio-Therapeutic Laboratory, Asheville, N. C.

This laboratory is licensed to manufacture all tuberculin preparations including Watery Extract of Tubercle Bacilli (von Ruck) and Tubercle Bacilli Emulsions (von Ruck); they are supplied only to physicians who make special applications for them.

Other Serum Products

ANTIRABIC VACCINE.—An emulsion of the cords of rabbits that have died as a result of the subdural injection of fixed rabies virus. The fixed virus is obtained by passage of rabies virus through a long series of rabbits until the animals die after a uniform period of incubation; this period may vary according to the strain of virus. The cords are removed from the rabbits and, as a rule, dried over potassium hydroxide for a period of from 2 to 15 days.

---

[1] The directions given by some manufacturers as to the method of using and the conclusions to be drawn from the use of their preparations seem to the Council to be open to criticism in certain respects. Thus many firms enclose droppers for use in making dilutions; droppers are not sufficiently accurate for use with strong solutions. ipettes, accurately calibrated in the metric system, should be used

Use.—Antirabic vaccine is used for the preventative treatment of rabies. Emulsions of the cords are prepared with broth or saline solution and injected subcutaneously. The "scheme of dosage" varies according to circumstances, but the general principle consists in daily injections, beginning with an emulsion of a cord dried for from 8 to 14 days and gradually increasing until a "2 day" cord is used.

H. M. Alexander & Co., Marietta, Pa.

Antirabic Vaccine. The fixed virus is of the strain employed by the Hygienic Laboratory, Washington, D. C. An emulsion of vaccine in glycerin sufficient for one dose, together with a syringe and needle, is contained in a vacuum tube by which a low temperature may be maintained for a period of 36 hours. A dose is sent each day by mail; the treatment requires 18 to 22 days.

ERYSIPELAS AND PRODIGIOSUS TOXINS (Coley).—Parke, Davis & Co., Detroit, Mich. A mixed culture of Streptococcus Erysipelatis and Bacillus Prodigiosus made according to the specifications of Dr. W. B. Coley. Marketed in 1 oz. bottles.

Action and Uses.—Loeb summarizes the results of the treatment of sarcoma with these toxins as follows: "It is therefore likely that the treatment of inoperable sarcoma with the toxins of streptococcus and Bacillus prodigiosus leads to a cure in approximately 4 to 9 per cent. of cases. And some results obtained so far suggest that this method of treatment may prove of value as a postoperative procedure in diminishing the number of recurrences, and that in a certain number of cases it might limit the necessity for amputation of the limb in cases of sarcoma of the long bones. As to its mode of action, nothing definite can be stated, but it is likely that the toxins themselves, as well as the local and general reactions they produce, frequently affect the life of the sarcoma cells unfavorably."

The toxins are injected in gradually increasing doses, at first in a part of the body removed from the tumor, and later, if possible, directly into the tumor itself.

NORMAL HORSE SERUM.—Injection of this has been recommended in various conditions where the coagulative power of the blood is deficient, as in hemophilia, severe anemias and purpura with hemorrhagic tendencies. Applied locally to bleeding surfaces it is said to act as a styptic and to have a favorable action on septic wounds. There is, however, an element of danger in the use of this or any other serum in certain conditions (Anaphylaxis), and while this is slight because of the rarity of dangerous effects it is sufficient to make the use of serums for purposes in which their value is extremely doubtful a questionable procedure.

National Vaccine and Antitoxin Institute, Washington, D. C.

Sterile Normal Horse Serum. Marketed in syringes containing 10, 15 and 20 Cc.

H. K. Mulford Co., Philadelphia.

Normal Serum (From the Horse). Marketed in packages of two syringes, each containing 10 Cc.

Noguchi Test for Syphilis

Noguchi test for syphilis is a modification of the method of Wassermann and involves the use of two standardized papers as follows:

Amboceptor Paper.—This is obtained by injecting washed human blood corpuscles (erythrocytes) into rabbits, at intervals of five to seven days, over a period of five or six weeks. Ten days are allowed to elapse after the last injection. The rabbits are then bled and the serum collected. Filter paper is now saturated with this serum and allowed to dry. The paper is cut in strips and set aside until wanted for use. In this form amboceptor will keep for a considerable length of time.

Amboceptor paper is standardized by measuring its specific activity. The measurement of specific activity consists of finding the amount of amboceptor necessary to cause hemolysis in 1 Cc. of suspended human red corpuscles, one drop of blood in 4 Cc. normal saline solution with 0.02 Cc. of fresh guinea-pig serum. Incubate this at a temperature of 37½ C. for one hour. The quantity of paper necessary to cause hemolysis under these conditions is known as 1 unit.

Antigen Paper.—Antigen is made by rubbing liver tissue with sand and extracting with alcohol. One Gm. of liver tissue is macerated in 10 Cc. of alcohol for one week at 37.5 C., shaking the container every day. It is filtered until clear and the filtrate evaporated. The resulting extract is dissolved in ether and this solution poured into a large quantity of acetone. The acetone precipitates certain lipoid substances, which are then collected and redissolved in ether-alcohol and constitute the antigen. Antigen papers are now prepared by saturating filter paper with this solution and allowing it to dry, after which it is cut into strips. The unit of standardization is the amount of antigen paper necessary to prevent hemolysis of human red corpuscles in the presence of syphilitic serum. The antigen paper must not of itself cause hemolysis.

H. K. Mulford Co., Philadelphia.

Noguchi Test Mulford. Noguchi test Mulford consists of amboceptor paper and antigen paper in a package accompanied with full directions for use.

Amboceptor Paper. Amboceptor paper is marketed in a glass tube.

Antigen Paper. Antigen paper is marketed in tubes containing acetone, because it is believed to prevent oxidation. When wanted for use, a strip of the paper is removed from the vial and the acetone allowed to evaporate.

SILVER CITRATE.—Silver citrate, $Ag_3C_6H_5O_7$, is the normal silver salt of citric acid.

Solution of citric acid is neutralized with sodium carbonate and a solution of silver nitrate added with constant stirring. The precipitate is allowed to subside, washed with water, and dried on porous plates. The entire operation must be conducted under protection from the light.

Silver citrate forms a white, odorless, heavy powder which is moderately sensitive to the light. It dissolves in 3,800 parts of water. On heating to redness a residue of metallic silver remains, weighing 63.16 per cent. of the original salt.

It should be carefully protected from the light.

Actions and Uses.—Silver-citrate is a non-irritating antiseptic.

It is said to be useful in the treatment of wounds, ulcers, gonorrhea and other affections of the mucous membranes.

Dosage.—It may be applied in substance to wounds. Solutions of from 1 to 4,000 to 1 to 10,000 are recommended for injection into the body cavities, the urethra, etc.

Proprietary Preparations:

ANTISEPTIC-Credé.—A name applied to Silver Citrate, which see.

Manufactured by Fabrik von Heyden, Radebeul, near Dresden, Germany (Schering & Glatz, New York).

SILVER LACTATE.—Silver lactate, $Ag.C_3H_5O_3 + H_2O$, is the normal silver salt of lactic acid.

It is prepared by dissolving freshly precipitated silver carbonate in a solution of lactic acid by the aid of heat and concentrating the solution until crystallization begins. The operation must be conducted in a darkened room.

Silver lactate forms colorless crystalline needles, turning brown on exposure to light; it dissolves in 15 parts of water. On heating it leaves a residue of metallic silver weighing 50.2 per cent. It is usually colored somewhat brown and gives with water a brownish or reddish solution. The salt must be protected from the light.

Actions and Uses.—The 1 to 300 to 1 to 500 aqueous solution is said to be equal in disinfecting power to a 1 to 1000 solution of mercuric chloride. It is irritating if applied in substance to wounds.

It is intended for all purposes for which a powerful antiseptic is desired.

Dosage.—1 to 100 to 1 to 2,000 solutions.

Proprietary Preparations:

SILVER LACTATE-Credé.—A name applied to Silver Lactate, which see.

Manufactured by Fabrik von Heyden, Radebeul, near Dresden, Germany (Schering & Glatz, New York).

SODIUM CACODYLATE—Sodii Cacodylas.—Sodium Dimethylarsenate.—Sodium cacodylate, $(CH_3)_2AsO.ONa + 3H_2O$, is the sodium salt of cacodylic acid (dimethyl arsenic acid), $(CH_3)_2AsO.OH$.

It is prepared by distilling arsenous oxide with potassium acetate, oxidizing the distillate, composed of cacodyl $AS_2 (CH_3)_4$, and cacodyl oxide, $(As_2 (CH_3)_4O$, with mercuric oxide, neutralizing the cacodylic acid with solution of sodium hydroxide and concentrating to crystallization.

It is a white powder, very soluble in water, forming needle-shaped crystals, hygroscopic, but otherwise of marked stability. The aqueous solution is alkaline toward litmus, but nearly neutral toward phenolphthalein.

On addition of silver nitrate T. S. to a solution of 1 Gm. of sodium cacodylate in 20 Cc. of water, a white precipitate is formed which is soluble in nitric acid and in ammonia water.

If to 1 Cc. of a 1 per cent. solution of sodium cacodylate 10 Cc. of hypophosphorous acid are added and put aside for 1 hour *in a closed container, a disgusting odor of cacodyl (caution on* account of extreme poisonous properties of the gas) is apparent (distinction from sodium monomethyl arsenate).

If calcium chloride T. S. solution be added to a solution of sodium cacodylate (1:20) no precipitate will be produced in the cold nor on warming (distinction from sodium monomethyl arsenate).

When warmed with ammonium molybdate T. S. a solution of sodium cacodylate (1:20) should not produce a yellow precipitate; nor should a yellow precipitate form when the 1:20 solution is treated with sodium thiosulphate T. S. or with hydrogen sulphide T. S.; nor should a white *precipitate form* when, after acidulating with hydrochloric acid, barium chloride T. S. is added to the 1:20 solution.

Estimation: A weighed quantity (approximately 1 Gm.) is dissolved in 25 Cc. of water, one drop of methyl orange T. S. added, and then normal hydrochloric acid V. S. added until a faint pink color appears; 1 Cc. normal hydrochloric acid V. S. = 0.2125 Gm. of sodium cacodylate. If to the finished titration phenolphthalein T. S. is added a volume of normal potassium hydroxide V. S. equal to the volume of normal acid used, should be required to produce a red color; $(CH_3)_2AsO.OH$ being a monobasic acid *toward phenolphthalein.*

Actions and Uses.—The action of sodium cacodylate is similar to other arsenic compounds, but it is said to be much less toxic than the ordinary preparations of arsenic and is also less apt to cause undesirable side effects. This superiority is due to the slow liberation of the arsenous acid in the body.

The cacodylate has been particularly recommended in obstinate psoriasis, pseudoleukemia, diabetes, anemia, chlorosis, tuberculosis, malarial cachexia, etc.

Dosage.—0.025 to 0.12 Gm. (½ to 2 grains) in pills, hypodermically or by enema.

SODIUM CINNAMATE—Sodii Cinnamas.—Sodium Phenylacrylate. Sodium cinnamate, $C_6H_5.CH:CH.COONa = NaC_9H_7O_2$, is the sodium salt of cinnamic acid (benzene-propenoic) acid, $C_6H_5CH:CH.COOH$.

Sodium cinnamate may be prepared by saturating a hot aqueous solution of sodium carbonate with cinnamic acid, evaporating and crystallizing. Cinnamic acid is obtained from balsam of tolu or may be produced synthetically by heating together benzaldehyde, sodium acetate, and acetic anhydride. By the latter method of preparation a purer product is produced which it is claimed is free from any by-effects of the acid from natural sources.

Sodium cinnamate is a white, crystalline powder, soluble in water, 1 part in 20, the solution being faintly alkaline. On boiling the alkalinity becomes stronger on account of the decomposition of the cinnamic acid forming sodium carbonate. Solution of sodium cinnamate (1 to 25) yields on the addition of ferric chloride a yellow precipitate. On adding it to potassium permanganate solution, the red color of the permanganate is destroyed and the odor of benzaldehyde developed. If a solution of sodium cinnamate is treated with dilute sulphuric acid, a precipitate of cinnamic acid appears, which after purification should melt at 133° C. (271.4° F.).

It is incompatible with acids and with oxidizing agents, e. g., potassium permanganate.

Actions and Uses.—Balsam of Peru, cinnamic acid and sodium cinnamate are recommended by Landerer for the treatment of phthisis, the drugs being injected intravenously under strict aseptic precautions. The effect is referred by him to an inflammatory reaction, localized about the tuberculous foci which leads to cicatrization. He records very favorable results in well-selected early cases, and other clinicians have also reported some successes, although the treatment fails very often. The synthetic cinnamate is preferred on account of its greater purity.

Dosage.—0.001 Gm. (1/60 grain), gradually increased to 0.02 Gm. (1/3 grain), in 1 to 5 per cent. solution, injected intravenously thrice weekly for long periods (3 to 18 months).

SODIUM LYGOSINATE—Sodii Lygosinas.—Lygosin Sodium. — Sodium lygosinate, $CO:(CH:CH.C_6H_4.ONa)_2 + 7H_2O = Na_2C_{17}H_{12}O_3 + 7H_2O$, is the sodium salt of dioxy-dibenzal acetone.

It is prepared by condensation of 2 molecules of salicylic aldehyde with 1 molecule of acetone and combining the product with sodium.

Sodium lygosinate occurs in glossy, greenish prisms, soluble in 16 parts of water at [illegible]8.4° C. (67.12° F.), or in about 9.5 parts at 37° C. (98.6° F.). It is soluble to the *extent of 1 per cent.* in cold alcohol, easily soluble in hot alcohol and in glycerin. Its aqueous solution has a ruby-red color and is alkaline in reaction.

On ignition, 1 Gm. *of* sodium lygosinate leaves a residue of sodium carbonate weighing 0.243 Gm. From the aqueous solution acids precipitate a thick yellow precipitate of diortho-cumarketone. The solution is fairly stable when kept in a cool place, protected from the air, and is not decomposed on boiling, but is decomposed by weak acids, even the carbonic acid of the air.

Actions and Uses.—The powder causes sneezing. Sodium lygosinate is said to possess a germicidal power similar to that of the silver salts, slightly weaker, but practically non-irritant. It is claimed to be useful in gonorrhea, especially of the uterus.

Dosage.—Injections of a 3 to 8 per cent. solution daily or every second or third day.

Manufactured by Vereinigte Chininfabriken, Zimmer & Co., Frankfort a. M., Germany. (C. Bischoff & Co., New York.) German patent No. 110,521. U. S. trademark No. 40,177.

SODIUM OLEATE[1]—*Sodii Oleas.*—Sodium oleate, $NaC_{18}H_{33}O_2$ is the sodium salt of oleic acid.

Sodium oleate is obtained by neutralizing sodium hydroxide with oleic acid.

Sodium oleate is a white solid, which crystallizes from absolute but not from aqueous alcohol. When heated it melts and burns leaving a residue of sodium carbonate. *It is soluble in about* 10 parts of water, in about 20 parts of alcohol, and in about 100 parts of boiling ether. When dissolved in water it is partly decomposed (hydrolysed) into oleic acid and sodium hydroxide; hence its aqueous solution has an alkaline reaction to phenolphthalein; its solution in strong alcohol is neutral to this indicator. It is precipitated from its aqueous solution by saturation with sodium chloride.

Acids separate from its aqueous solution oleic acid, which collects at the surface of the liquid, in an oily layer. If a solution of 5 Gm. of sodium oleate, in 50 Cc. of water be mixed with 3 Cc. of tenth-normal *oxalic acid solution*, the subsequent addition of a few drops of phenolphthalein test solution should not produce a pink coloration.

An aqueous solution of sodium oleate (1 in 20) should remain unchanged in color upon the addition of ammonium sulphide test solution; and upon acidulating another portion of the solution with hydrochloric acid and filtering, the filtrate should remain unchanged in color when an equal volume of hydrogen sulphide test solution is added and the mixture is allowed to stand well stoppered in a warm *place for half* an hour (absence of metallic impurities).

Action and Uses.—Sodium oleate is antacid and mildly laxative. It is commonly added to laxative pills. It has been claimed without any definite evidence that it is especially useful in disease of the biliary tract.

Dosage.—0.12 to 1.3 Gm. (2 to 20 grains).

SODIUM PERBORATE—Sodii Perboras.

Sodium perborate, $NaBO_3.4H_2O$, is the sodium salt of perboric acid. It should contain not less than 9 per cent. of available oxygen.

Sodium perborate may be prepared by the action of an alkali peroxide and carbon dioxide on an alkali borate (U. S. Pat. No. 842,470) and by other methods.

Sodium perborate occurs as a white granular salt, odorless and soluble in water; the solution has a saline taste. It is decomposed by water into hydrogen peroxide and sodium metaborate, $NaBO_3 + H_2O = H_2O_2 + NaBO_2$ producing an alkaline solution. It is decomposed by catalyzers, ferments and animal tissues. Heated to 60° C. (140° F.) it evolves oxygen and when heated to a higher temperature it gradually loses all its available oxygen and water *of crystallization.*

On adding to 10 Cc. water in a test tube, one drop of potassium dichromate test solution then ten drops of dilute sulphuric acid and pouring a few Cc. of ether *on top, the subsequent* addition of a few drops of an aqueous solution of sodium perborate will cause a blue color to appear at the zone of contact of the two liquids. After shaking the ether layer will separate with a blue color.

If 0.20-0.03 Gm. sodium perborate accurately weighed be dissolved in 50 Cc. water and 10 Cc. dilute sulphuric acid added, *to produce* a permanent pink color, not less than 11.25 Cc. tenth normal permanganate solution should be required for each 0.1 Gm. of substance taken (indicating not less than 9 per cent. of available oxygen).

Action and Uses.—Sodium perborate is an antiseptic, deodorant and bactericide, and is used in wounds, purulent sores, varicose ulcers, etc. In general, it is used *in place* of hydrogen peroxide, over which it has the advantage of yielding an alkaline solution. It is applied as a dusting powder or in a 2 per cent. solution.

Non-proprietary Preparation:

Sodium Perborate Merck.—Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York).

---

[1] This preparation should not be confounded with the preparations sold as "Acid sodium oleate" or "Sodium Oleate, acid" which are mixtures of sodium oleate and free oleic acid, containing from about 5 to 30 per cent. of the latter.

Proprietary Preparation:

PEROGEN BATH—Oxygen Bath Salts. Perogen.—Perogen bath is a preparation consisting of a catalyzer and sodium perborate capable of yielding 10 per cent. of oxygen, the two substances being wrapped separately.

The catalyzer is a light yellow odorless powder, and is made by a method which is the subject of a patent application now pending. The oxygen contents may be determined by any of the well-known methods.

Actions and Uses.—The catalyzer is a medicinally indifferent substance. When the two substances are mixed with water the catalyzer causes the liberation of the available oxygen of the sodium perborate. The oxygen bath thus obtained is said usually to reduce blood pressure and the pulse rate to a much greater extent than the ordinary bath. It is claimed to have marked tranquilizing and somnifacient effects. It is said to be useful in cardiac affections with high vascular tension and excitement, neuroses, insomnia, chronic nephritis, and skin diseases in which hydrogen dioxide is indicated.

Dosage.—One bath daily until 24 or 48 have been taken, with occasional intermissions.

Manufactured by Morgenstern & Co., New York. U. S. trademark 75,982. U. S. patent No. 969,073 (Aug. 30, 1910; expires 1927).

SODIUM PEROXIDE—Sodii Peroxidum.—Bioxydum natri (Pharm. Hispanola, edit. vii).

Sodium Peroxide is the sodium salt of hydrogen peroxide containing *at least 75 per cent.* Na_2O_2.

Sodium peroxide occurs in the form of a white, or yellowish, amorphous powder. It is soluble in water, with evolution of heat, and forms a solution of hydrogen peroxide, from which latter, oxygen is liberated by the heat of the reaction. It dissolves in cold dilute acids forming a solution of hydrogen peroxide. When heated sodium peroxide becomes darker, but on cooling resumes its original color. It does not react with alcohol, but it ignites ether on contact. A mixture with red phosphorus explodes under pressure or on being struck. It is an extremely powerful oxidizing agent.

Sodium peroxide should not respond to tests for sulphates, chlorides, phosphates, nitrogen and heavy *metals.*

Action and Uses.—Sodium peroxide is not used internally but has been used in acne, applied in the form of a paste prepared with liquid paraffin, or as a *soap to remove comedones.*

It has been suggested as an air purifier, based on the theory that the moisture of the air would liberate oxygen and the alkali simultaneously formed would absorb carbon dioxide.

Proprietary Preparation:

OXONE.—Oxone is a name applied to fused sodium peroxide containing a fractional percentage of a catalytic agent. It is said to yield its entire content of available oxygen in gaseous form, upon contact with water.

Manufactured by the Roessler & Hasslacher Chemical Co., New York. U. S. patent No. 788,256 (April 25, 1905; expires 1922). U. S. trademark *No.* 46,673.

SOLUTION OF FORMALDEHYDE

Solution of Formaldehyde is official in the United States Pharmacopeia. For description see the pharmacopeia or the Physician's Manual of the Pharmacopeia and National Formulary.

FORMALIN.—A name applied to *Liquor Formaldehydi,* U. S. P.

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, Berlin, Germany (Schering & Glatz, New York). U. S. trademark No. 65,625.

SOPHOL.—Sophol is a compound of silver and methylennucleinic acid, the silver being in organic ("masked") form.

It is prepared by conversion of *insoluble silver* compounds of methylennucleinic acid into soluble silver *compounds* by treatment with neutral salts, such as chloride of sodium. Sophol is a yellowish powder, having a *metallic* taste and claimed to contain silver, equivalent to *not less than 20* per cent. metallic silver. Sophol is readily soluble in water, the aqueous solution having a faint alkaline reaction; it does not give a precipitate on the addition of dilute solution of sodium hydroxide or of sodium chloride; it is insoluble in ether and alcohol.

If 0.3 Gm. sophol is heated in a test-tube [illegible] [illegible] urs with the development of brownish-red [illegible] [illegible] If the ash is treated with dilute nitric acid, [illegible] [illegible] a white cheesy precipitate is formed on *addition of* hydrochloric acid, which dissolves in ammonia water.

If 0.5 Gm. sophol is boiled with 5 Cc. *of sodium* hydroxide solution, the latter assumes a black color with the development of a formaldehyde odor.

If 0.1 Gm. sophol is heated with 3 Cc. nitric acid, a dirty yellow precipitate is formed, disappearing on addition of an excess of ammonia water with the formation of an orange colored solution.

A solution of 0.5 Gm. sophol in 10 Cc. water should have a faintly alkaline reaction and should not at once become turbid on the addition of sodium chloride solution.

If 1.0 Gm. sophol is shaken with 10 Cc. of alcohol and filtered, the filtrate should not be changed on addition of hydrochloric acid.

Actions and Uses.—It is said to act as a germicide and to be free from irritating effects in the solutions ordinarily employed.

It is said to be especially useful for the prevention and treatment of ophthalmia neonatorum and may be employed *in* other eye affections and for the *general indications* of the silver salts.

Dosage.—Sophol may be applied in from 2 to 5 per cent. solutions.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 852,545 (May 7, 1907; expires 1924). U. S. trademark No. 62,900.

SPIROSAL.—Spirosal is monoglycol salicylate, $C_6H_4OH.CO.O.CH_2.CH_2.OH = C_9H_{10}O_4$, the salicylic acid ester of monoglycol.

It is prepared by the action of ethyleneglycol on salicylic acid.

Spirosal is an almost odorless and colorless *oily fluid, with* a boiling point of 169° to 170° C. (336.2° to 338° F.) at 12 *mm.* pressure. It is easily soluble in alcohol, ether, chloroform and benzol and soluble in about 110 parts of water and 8 parts of olive oil.

Tests. 0.5 Gm. spirosal is saponified with 5 Cc. soda lye by slight warming, the clear fluid diluted with water and acidified with dilute sulphuric acid; fine crystalline needles of salicylic *acid are formed,* which *after being* extracted with ether and the latter then evaporated, can be identified by *the melting point* and ferric chloride reaction. The saturated watery solution *obtained* by shaking 1 Cc. spirosal with 50 Cc. of water gives *a filtrate,* which becomes intensely violet on addition of ferric chloride, but should not be changed by barium nitrate or silver nitrate; *0.5 Gm.* of spirosal *when added* to 2 Cc. of concentrated sulphuric acid should be given a light yellow and not a brownish color; 0.3 Gm., if incinerated on platinum foil, *should* not leave any weighable residue.

Actions and Uses.—Spirosal is said to be easily absorbed by *the skin* without causing irritation even when rubbed in thoroughly. It splits off salicylic acid *in the tissues.*

Spirosal is said to be useful for the external treatment of *rheumatic* affections.

Dosage.—It is used undiluted or mixed with 2 to 3 parts of alcohol or in a mixture with olive oil, 1 to 8, *or in ointments* with equal parts by *weight of petrolatum* or lard.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany. (Farbenfabriken of Elberfeld Co., New York.) U. S. patent No. 794,982 (July 18, 1905; expires 1922). U. S. trademark No. 62,856.

STOVAINE—Benzoyl-Ethyl-Dimethylaminopropanol Hydrochloride.—Stovaine is 2-benzoxy-2-methyl-1-dimethyl-amino butane hydro*chloride,* $CH_3.CH_2.C(C_6H_5COO)(CH_3)CH_2N(CH_3)_2.HCl = C_{14}H_{22}O_2NCl$. It is closely related to alypin (which see).

It is prepared by causing a reaction of benzoyl chloride on the *a*-dimethyl-amino-pentonal-*b*, which is itself the product of reaction of ethylmagnesium *chloride on methy*laminoacetone.

It crystallizes *in small,* brilliant scales, which melt at 175° C. (347° F.). *It is extremely* soluble in water and easily in methyl alcohol and acet[illegible] arts of absolute alcohol for solution and [illegible] *n acetone.* It is quite stable and its s[illegible] *at 115°* C. (239° F.) without suffering [illegible]

The aqueous [illegible] to litmus, neutral to methyl orange. It is *precipitated by* all the alkaloidal reagents and is decomposed even by very dilute alkalies.

It is incompatible with alkalies *and all alkaloidal* reagents.

Actions and Uses.—Stovaine acts as a local anesthetic. It has about the same power as cocaine, but dilates the blood vessels, whereas cocaine contracts them. It is only ⅓ to ½ as toxic as cocaine. Stovaine also is said to exert a tonic action on the heart.

It is used as a local anesthetic; while most reports are favorable, one case of gangrene has been reported following the use of a 10 per cent. solution.

Dosage.—Internally, 0.002 Gm. (1/30 grain) pill form. Locally it may be used in the eye in 4 per cent solution and applied to other mucous membranes, as in laryngology, in from 5 to 10 per cent. solution. For hypodermic injections for local anesthesia it can be used in 0.75 to 1 per cent. solution.

nufactured by the Poulenc Frères Co., Paris, France (Parmele macal Co., New York). U. S. patent Nos. 829,262; 829,374 21, 1906; expires 1923); 828,846 (Aug. 14, 1906; expires). U. S. trademark No. 59,228.

PHANTHIN THOMS.—Strophanthin Thoms is a ne glucoside ($C_{30}H_{46}O_{12} + 9H_2O$), obtained from Stronthus gratus. It is identical with the ouabain obtained Ouabaio wood by Arnaud (the official strophanthin is thyl-ouabain ($C_{31}H_{48}O_{12}$).).

The light-brown dehaired seeds of strophanthus gratus are d pressed to free from oil. The oil free cakes thus formed are ken up and extracted with 96 per cent. alcohol. The alcohol distilled off on the water bath, leaving a residue, which is described as follows: It consists of several layers—an upper thin layer of oil, then an aqueous alcohol layer, followed by a yellowish brown mass of crystals, under which is a layer of a brown extract, from which an amorphous strophanthin can be isolated. The above mentioned crystals are freed from the mother liquor and recrystallized from hot water. The seeds yield about 3.62 per cent. of crystallized strophanthin.

Colorless quadratic crystals of bitter taste and easily soluble in hot water. Soluble in 100 parts of cold water and 30 parts cold absolute alcohol and 30 parts amyl alcohol. It is slightly soluble in acetic ether, ether and chloroform. Its solubilities require further study. Solutions of 1 part of crystallized strophanthin in 100 parts of 95 per cent. alcohol have been frequently observed to deposit crystals on standing.

A solution of 0.01 gm. in 1 Cc. water run onto a layer of concentrated sulphuric acid colors the latter pink to red and the aqueous layer is colored a dirty green color.

Heated to 105° C. (221° F.), it loses 20 per cent. of water. The strophanthin thus dried melts at 187° to 188° C. (368.6° to 370.4° F.). Upon ignition no weighable residue should remain.

Heating with dilute hydrochloric acid or sulphuric acid produces hydrolytic cleavage, yielding a body which is identical with rhamnose.

Action and Uses.—Its pharmacologic action is probably qualitatively identical with that of the official strophanthus *or strophanthin, but the crystallized* is more than twice as active as the official strophanthin when injected subcutaneously or intravenously. The action of crystallized strophanthin appears to be identical with that of the purest preparation of strophanthin from Strophanthus Kombé; this action develops more rapidly, the drug is more quickly excreted, and shows less tendency to cumulative action than is the case with digitalis.

Strophanthin Thoms is used in place of strophanthus as a substitute for digitalis.

Dosage.—It is recommended in doses of 5 minims of a 1 per cent. solution by the mouth, *gradually increased by 1 minim* until the desired effect is obtained, which seldom requires more *than ten minims* (or *about one-tenth of* a grain of strophanthin). (H. Schedel, Arbeit a. d. Pharm. Inst. d. Universität, Berlin, II, 1904, p. 97). Single dose by mouth, 0.003 to 0.025 Gm. (1/20 to 2/5 grain); daily dose, up to 0.03 Gm. (½ grain). The larger doses are probably not absolutely safe. Intramuscularly or intravenously: The correct dose has not been accurately determined, but it appears to be one-half milligram (1/130 grain) or less for a single dose, and only one such dose should be given in a day as a rule. For intramuscular injection it should be dissolved in about 4,000 parts of distilled water, and even in that dilution it occasions some pain. *The intramuscular injection should be* repeated only by the physician himself.

SUBLAMINE—Mercuric Sulphate-Ethylenediamine.—Sublamine, $HgSO_4.2C_2H_4(NH_2)_2 + 2H_2O$, is a compound of one molecule of mercuric sulphate with two molecules of ethylenediamine (which see).

It forms white needles, readily *soluble* in water and in 10 parts of glycerin, sparingly soluble in alcohol. It has an alkaline reaction; it contains *about* 44 *per* cent. of mercury. It does not precipitate albumin from its solutions.

It is incompatible with sodium chloride and should not be exposed *to the air.*

Actions and Uses.—Sublamine is a disinfectant, similar to mercuric chloride, over which it has the advantage of being non-irritating, more penetrating and readily soluble.

It is used as a substitute for mercuric chloride for hand disinfection, as well as in *dermatology*, gynecology, ophthalmology and *otology*.

Dosage.—It is used *in* a 1:1,000 solution for skin disinfection and in 1:5,000 solution for irrigations of the bladder, etc. It may be used in syphilis by injection into the gluteal muscles of a 3 or 4 per *cent.* solution.

Manufactured by Chemische Fabrik auf Actien, vorm. E. Schering, *Berlin*, Germany (Schering & Glatz, New York). U. S. patent No. 726,126 (April 21, 1903; expires *1920*). *U. S.* trademark No. 37,736

SULPHANILIC ACID.—Acidum Sulphanilicum.—Acidum Sulfanilicum (Pharm. Helvetica, edit. 4).—Sulphanilic acid, $C_6H_4(NH_2)$ (HSO_3) 1:4, is para-amino-benzene-sulphonic acid.

Twenty-five Gm. colorless aniline are gradually added to 75 Gm. concentrated sulphuric acid in a 250 Cc. flask and the mixture warmed to 180° *to* 190° C. *(356° to 374° F.)*, under *agitation* for about three hours or until a drop of the mixture dropped into a solution of potassium hydroxide no longer gives indication of the presence *of aniline. At the end of the reaction* the mixture is poured into 500 Cc. *cold* water which precipitates the sulphanilic acid as a grayish crystalline powder; it is treated with animal charcoal and recrystallized *from* hot *water* (*Hager* 1, p. 116).

It occurs as colorless crystals slightly soluble in water, and insoluble in alcohol and ether. It is decomposed at 280° to 300° C. (536° to 572° F.). *It effloresces in air. It is soluble in* 182 parts water at 0° C. (32° F), and in 166 parts water at 10° C. (50° F.). It is not altered by boiling alkali, but fusion with alkali decomposes it, *yielding aniline. Chromic acid mixtures* oxidize it to chinon. Permanganate oxidizes it to azo-benzene-sulphonic acid and an excess of this reagent to carbon dioxide, sulphuric acid, ammonia and oxalic acid. The *cold saturated* solution is not altered by hydrogen sulphide or barium chloride, but boiling with alkali should produce a visible change (Pharm. Helvetica, edit. 4). One Gm. of the *powdered acid treated with* 3 Cc. zinc chloride solution should not be darkened. It should leave no residue on ignition (Pharm Helvetica, edit 4).

Uses and Dosage.—Internally (of doubtful value) in chronic catarrh of the respiratory mucosæ, 0.5 to 2 Gm. (10 to 30 grains) three times a day. It may be rendered more soluble by sodium bicarbonate. Its most important use is in Ehrlich's diazo-reaction for typhoid urines.

Proprietary Preparation:

SOLOID NIZIN.—Tablets, each of which contains 0.13 Gm. (2 grains) of zinc sulphanilate, $Zn(C_6H_4(NH_2)SO_3)_2 + 4H_2O = Zn(C_6H_6O_3NS)_2 + 4H_2O$.

Actions and Uses.—Soloid Nizin is said to be an astringent and antiseptic. It is said to be useful in gonorrhea, in conjunctivitis *and* other eye *affections.*

Dosage.—One to three in 30 Cc. (one fluidounce) of water for urethral injection. One in 60 Cc. (2 fluidounces) for an eye lotion.

Prepared by Burroughs, *Wellcome & Co., London, England,* and New York. U. S. trademark No. 287,163.

SULPHONMETHANE.

Sulphonmethane is official in the United States Pharmacopeia. For description see the pharmacopeia or the Physician's Manual of the Pharmacopeia and National Formulary.

SULPHONAL.—A name applied to Sulphonmethanum, U. S. P.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 391,875 (expired).

SULPHONETHYLMETHANE.

Sulphonethylmethane is official in the United States Phar macopeia. For description see the *pharmacopeia* or the ician's Manual of the Pharmacopeia and National Forn

TRIONAL.—A name applied to Sulphonethylmeth U. S. P.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New U. S. patent *No.* 396,526 (expired).

SULPHURATED POTASH—Potassa Sulphurata sulphuratum crudum—Hepar Sulfuris.—Sulphurated po a mixture of salts of potassium, of which the chief are po sium sulphides (Br. Pharm., p. 259).

It is prepared as follows: Mix the powdered and dried potassium *carbonate thoroughly with the sublimed sulphur,* and gradually heat the mixture, in a covered crucible. which *should be only* about half filled with it, until the mass ceases *to foam* and is in a state of perfect fusion. Then pour the fused mass on a cold marble slab, and, after it has cooled, break it into pieces, and keep it in a *well-stoppered bottle (U. S. P., 1890, p. 313).*

When freshly prepared, sulphurated potassa forms irregular pieces of a liver-brown color, which, by *exposure to the air*, gradually *absorb moisture, oxygen* and carbon dioxide, and change to a greenish-yellow and finally to a gray mass containing potassium carbonate, thiosulphate and sulphate. The compound has a faint odor of hydrogen sulphide, and a bitter, alkaline taste.

Soluble in 2 parts of water at 15° C. (59° F.), with the exception of a small residue. Alcohol dissolves only the potassium sulphide, leaving the other constituents (thiosulphate and sulphate) undissolved.

The aqueous solution (1 in 10) is of an orange-yellow color, is strongly alkaline to litmus paper, and gives off the odor of hydrogen sulphide.

On adding to it acetic acid in slight excess, an abundance of hydrogen sulphide is evolved, while sulphur is precipitated.

In this liquid, after filtration, sodium bitartrate test solution produces an abundant, white, crystalline precipitate (U. S. P., 1890, p. 213).

On triturating 1 Gm. of sulphurated potassa with 1 Gm. of crystallized copper sulphate and 10 Cc. of water, and filtering, the filtrate should remain unaffected by hydrogen sulphide test solution, corresponding to at least 12.85 per cent. of sulphur combined with potassium to form sulphide (U. S. P., 1890, p. 813).

Actions and Uses.—Externally sulphurated potash acts as an irritant and softens the horny layers of the skin, acting especially on the hairs. Internally, it is a gastrointestinal irritant and is believed to be an alterative. In some cases it has produced severe poisoning from the amount of hydrogen sulphide evolved. It is employed externally[1] as a local irritant in various skin diseases and as a parasiticide.

TANNALBIN—Albuminis Tannas.—Tannate of Albumin.—Tannalbin is a compound of tannic acid and albumin thoroughly exsiccated.

It is prepared by precipitating 10 parts of a 10 per cent. solution of egg albumin with 6.5 parts of a 10 per cent. solution of tannic acid, washing the precipitate with water until the washings react only faintly with ferric chloride, drying it on porous tiles, powdering, and heating the product at 126° C. (258.8° F.) for six hours.

It is a light brown, odorless and tasteless powder, containing about 50 per cent. of tannic acid. It is practically insoluble in water or alcohol, but slowly soluble in alkaline fluids, which split it up into its constituents.

The filtrate obtained after shaking tannalbin with water should give, at most, a faint reaction with ferric chloride.

It is incompatible with alkaline liquids.

Actions and Uses.—Tannalbin is astringent. Being insoluble in the gastric juice, it becomes effective when it reaches the intestines, where it slowly splits off tannic acid. It does not produce gastric disturbance.

It is said to be useful in diarrhea, especially in that of children, and in phthisis.

Dosage.—1 to 4 Gm. (15 to 60 grains) in powder (or tablets) followed by water; infant doses, 0.3 to 0.5 Gm. (5 to 8 grains) in gruel or other mucilaginous liquid.

Manufactured by Knoll & Co., Ludwigshafen a. R., Germany, and New York. U. S. patent No. 563,479 (July 7, 1896; expires 1913). U. S. trademark No. 28,348.

TANNIGEN—Acidum Tannicum Diacetylicum.—Diacetyl-Tannin.—Tannigen is tannyl acetate, $C_{14}H_8(C_2H_3O)_2O_9 = C_{18}H_{14}O_{11}$, the acetic acid ester of tannin.

It is prepared by heating tannin and acetic anhydride, in molecular proportions, in the presence of glacial acetic acid in a flask under a reflux condenser, pouring the product of the reaction into water, washing the precipitate produced with warm water, drying and powdering.

It is a light-gray, almost odorless and tasteless powder, which undergoes no change when heated alone, even to 180° C. (356° F.), but softens when heated in water at 50° C. (122° F.). It is practically insoluble in cold water, scarcely soluble in hot water, but soluble in alcohol, and also in solutions of borax, sodium [illegible] bonate, lime, etc., being reprecipitated from [illegible] cids. It is rapidly saponified by boiling [illegible] hydroxide solutions, or gradually in the cold, into acetic and gallic acids, while ammonia produces acetic and tannic acids.

Its aqueous solutions produce with ferric salts a green color, instead of the blue-violet color characteristic of tannic acid. A slightly alkaline solution in [illegible] its all the characteristics of an astringent [illegible], but these properties are destroyed by borax or more alkali.

It is incompatible with alkalies and with salts of iron; it should not be exposed to heat or moisture.

Actions and Uses.—Tannigen passes unchanged into the intestine, where it becomes effective as an astringent in contact with the alkaline juice. It is said to be free from irritant action. (See note under Cresosote Carbonate.)

It is said to be useful in acute diarrheal affections, such as acute intestinal catarrhs, cholera morbus, cholera infantum and dysentery; it has also been used with reported success for the diarrhea of typhoid fever and intestinal tuberculosis.

Dosage.—0.2 to 0.7 Gm. (3 to 10 grains) four times per day, dry on the tongue followed by a swallow of water; or mixed with food, avoiding warm or alkaline liquids.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York.) U. S. patent No. 533,718 (Feb. 5, 1895; expires 1912). U. S. trademark No. 17,668.

TANNISMUTH—Bismuthi Bitannas.—Bitannate of Bismuth. Tannismuth is the bismuth salt of tannic acid in which approximately one atom of bismuth is combined with two molecules of tannic acid having approximately the formula Bi (OH) $(C_{14}H_9O_9)_2$ and containing between 17 and 21 per cent. bismuth.

It is a light yellow powder with slightly astringent taste, insoluble in water, soluble in cold caustic alkalies, and in diluted hydrochloric acid.

Actions and Uses.—It is claimed that one molecule of the tannic acid becomes operative immediately after ingestion, while the other is slowly separated and prolongs the astringent action throughout the entire length of the alimentary canal.

It is said to be useful in chronic intestinal catarrh, involving different portions of the intestinal tract.

Dosage.—0.3 to 0.6 Gm. (5 to 10 grains) three to five times daily.

Manufactured by Chemische Fabrik von Heyden, Radebeul near Dresden, Germany (The Heyden Chemical Works, New York). Not patented in the United States. German patent No. 172,933. U. S. trademark No. 36,916.

TANNOFORM — Tanninformaldehydum. — Tanninformaldehyde—Methylenditannin—Tannoform, $CH_2(C_{14}H_9O_9)_2 = C_{29}H_{20}O_{18}$, is a condensation product of formaldehyde with gallo-tannic acid.

It is prepared by mixing solutions of formaldehyde and tannic acid, precipitating with concentrated hydrochloric acid, washing the precipitate with water, and drying.

It forms a voluminous, reddish powder, odorless and tasteless. It is insoluble in water, but soluble in alkaline liquids and in alcohol. 0.01 Gm. of tannoform dissolved in 2 Cc. concentrated sulphuric acid forms a brown solution which on warming becomes green and later changes to blue. The green or blue solution, on addition of alcohol, assumes a brilliant blue color, which gradually changes to wine color, while on addition of dilute sodium hydroxide the color is pale green.

Its incompatibilities are those of tannin generally.

Actions and Uses.—Tannoform is astringent and antiseptic. It is said to be useful an account of these properties in chronic intestinal catarrh and externally in hyperidrosis, bromidrosis, weeping eczema, ozena, etc.

Dosage.—0.25 to 0.5 Gm. (4 to 8 grains); externally, pure or in 25 to 50 per cent. triturations (with talc) as dusting powder, or as 10 per cent. ointment or soap.

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York). German patents Nos. 88,082 and 88,841.

TANNOPIN—Hexamethylene-Tetramine-Tannin.—Tannon.—Tannopin, $(C_{14}H_{10}O_9)_3.CH_2)_6N_4 = C_{48}H_{42}O_{27}N_4$, is a condensation product of tannin with hexamethylenamine

It is prepared by mixing molecular proportions of solutions of hexamethylenamine and tannic acid, collecting, washing and drying the precipitate.

It is a fine, fawn-colored, odorless and tasteless, non-hygroscopic powder, containing 87 per cent. of tannin and 13 per cent. of hexamethylenamine. It is insoluble in water, weak acids, alcohol, chloroform or ether, but slowly soluble in dilute alkalies. On heating dry tannopin, it swells and gives off the odor of formaldehyde. The odor of formaldehyde is also developed on heating tannopin with dilute sulphuric or hydrochloric acid, while on boiling with sodium hydroxide solution it splits off ammonia. The clear aqueous filtrate from tannopin does not give a reaction with ferric chloride.

It is incompatible with alkalies.

Actions and Uses.—Tannopin has an astringent and antiseptic action in the intestine; it passes unchanged through the stomach, but, being gradually decomposed by alkalies, it becomes effective in the intestinal tract, exerting the action of its two components.

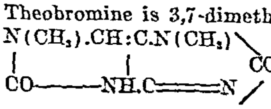
It is said to be useful in acute, subacute or chronic intestinal catarrh, in tuberculous enteritis, and other intestinal disorders.

Dosage.—0.3 to 0.5 Gm. (5 to 8 grains) for infants and children; 1 Gm. (15 grains) for adults, dry on the tongue, followed by a swallow of water, or sprinkled on food, four times a day.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. patent No. 607,172 (July 12, 1898; expires 1915). U. S. trademark No. 31,527.

THEOBROMINE AND THEOBROMINE COMPOUNDS.

***THEOBROMINE*—Theobromina. — 3,7-Dimethyl-Xanthine.**—Theobromine is 3,7-dimethyl xanthine,



$$\begin{array}{l} N(CH_3).CH{:}C.N(CH_3) \\ | \qquad\qquad | \\ CO — NH.C = N \end{array} \Big\rangle CO$$

$= C_7H_8O_2N_4$, a base occurring in

---

[1] In view of the uncertainty of the composition of sulphurated potash and of the fact that it sometimes exerts a poisonous action, it is deemed suitable only for external use.

Theobroma cacao, Kola acuminata, etc., and also made synthetically. Theobromine is closely related to caffeine (1,3 7 trimethyl xanthine).

It is a white, crystalline powder, odorless and bitterish. It is almost insoluble in cold water or chloroform, readily soluble in hot alcohol and in ether. *It forms salts with acids.*

Actions and Uses.—Its uses are similar to those of caffeine, but its action is said to be relatively *greater on the heart and* muscles and also as a diuretic. It does not act so powerfully on the central nervous system.

It is used as a diuretic. The great obstacle to its use has been its insolubility and the consequent uncertainty of the degree of its absorption. It is liable to produce gastric disturbances.

Dosage.—0.35 to 0.5 Gm. (5 to 8 grains).

AGURIN — Theobrominæ Sodio-Acetas. — Theobromine-Sodium-Acetate.—Agurin, $NaC_7H_7N_4O_2 + NaC_2H_3O_2$, is a double salt of sodium acetate and theobromine-sodium.

It is prepared by adding to a solution of one molecule of sodium hydroxide one molecule of theobromine. To this solution of sodium theobromine one molecule of sodium acetate is added and the solution brought to dryness.

It is a white, finely crystalline powder, containing 60 per cent. of theobromine. It is freely soluble in water, not very readily soluble in cold, more so in hot, alcohol. It is quite hygroscopic, and in watery solutions gradually splits up into its components, and more readily in the presence of carbon dioxide.

It is precipitated and decomposed by carbon dioxide and by acids; it forms a bluish white precipitate with silver nitrate, a blue precipitate with copper sulphate, white with tartar emetic, red-brown with ferric salts. It is not readily precipitated by Mayer's reagents, nor by iodine.

It is incompatible with carbonated beverages, acids, saccharine and mucilaginous liquids, and most of the alkaloid reagents.

Actions and Uses.—It acts like theobromine, over which it has the advantage of great solubility and that it is well tolerated by the stomach. While inferior in diuretic power to theophyllin (which see), it is said to have greater power in sustaining the diuresis produced.

Dosage.—0.5 to 1 Gm. (7 to 15 *grains*), *preferably in* wafers *or capsules. If in solution, this should be freshly pre*pared (with peppermint water) and without sugar or mucilage.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. trademark.

Tablets Agurin, 5 grains. Each tablet contains agurin 0.33 Gm. (5 grains).

THEOBROMINE SODIUM SALICYLATE — Theobrominæ Sodio-Salicylas.—Theobromine sodium salicylate, $NaC_7H_7N_4O_2 + NaC_7H_5O_3$, is a double salt of theobromine-sodium and sodium salicylate. It is official in the German Pharmacopeia as *Theobrominum natrio-salicylicum.*

It is prepared by adding to a solution of one molecule of sodium hydroxide one molecule of theobromine. To this solution of sodium theobromine one molecule of sodium salicylate is added *and the solution brought to dryness.*

It is a white powder, odorless, having a saline taste, and containing 50 per cent. of theobromine. It is freely soluble in water, and, like "theobromine sodium-acetate" *(see Agurin) is readily* decomposed by exposure to carbon dioxide or by the action of acids. *It must* therefore be preserved in well-stoppered bottles.

The aqueous solution (1 to 5) is colorless, turns litmus paper blue and after acidification with acetic acid assumes a violet coloration on addition of ferric chloride solution. *From the solu*tion, hydrochloric acid precipitates salicylic acid, and, after a *time, also* theobromine, the precipitate being completely soluble in sodium hydroxide solution, but not in ammonia water. If 10 Cc. *of the solution*, rendered clear by the addition of sodium hydroxide solution, is shaken with 10 Cc. of chloroform, the chloroform when separated and evaporated should leave a residue not exceeding 0.005 Gm. for 1 Gm. theobromine sodium salicylate.

It is incompatible with acids, bicarbonates, borates, phosphates, ferric salts, hydrated chloral, etc.

Actions and Uses.—Its effects are the same as those of theo*bromine (which see), over* which it has the advantage of greater solubility.

Dosage.—1 Gm. (15 grains) five or six times a day. Its tendency to produce gastric irritation may be prevented by giving it in well-diluted solution, or, if preferred, in capsules or wafers, followed by water.

THEPHORIN—Theobrominæ Sodio-Formas. — Theobromine Sodium Formate. Thephorin is theobromine sodio-formate, $NaC_7H_7N_4O_2 + NaCHO_2 + H_2O$, a double salt of sodium formate and theobromine sodium.

It is prepared by dissolving 70.1 parts of theobromine sodium in 200 parts of water and adding to it a solution of 23.5 parts of anhydrous sodium formate in 50 parts of water, filtering the mixture, and evaporating to dryness on a steam bath or in vacuo.

Thephorin is a white, odorless powder having a saline bitter taste and is readily soluble in water producing an alkaline solution. From its aqueous solution the theobromine is precipitated by acetic acid. *In the filtrate formic* acid is indicated by the reduction of silver nitrate.

If an aqueous solution of thephorin be faintly acidulated with nitric acid, the filtrate should give no *precipitate with barium* chloride, nor with silver nitrate, nor with ammonia water and hydrogen sulphide.

Two Gm. thephorin are placed in a porcelain dish and dis*solved in 10* c.c. water with the aid of gentle heat. A few drops of phenolphthalein test solution are *placed* in the solution, neutralized with nitric acid, the faint alkaline reaction is again restored *by means of diluted ammonia*, the solution is then thoroughly stirred and, with frequent stirring, allowed to stand for three hours at ordinary temperature.

The resulting precipitate collected on a weighed filter of 8 cm. diameter, is dried at a temperature of 100 C.; it is then washed twice with cold water, using 10 Cc. *each time. The filter is* again dried at a temperature of 100 C. and weighed. The weight of the precipitate should amount to 1.2 Gm.

Actions and Uses.—Thephorin is said not to irritate the *stomach and acts as a powerful* diuretic, both on account of the theobromine which it contains and also from the action of sodium formate.

It is said to be useful in cardiac affections, nephritis, dropsy, etc.

Dosage.—0.5 Gm. (7½ *grains) two or three times a day in* the form of powder or as tablets.

Manufactured by F. Hoffmann-LaRoche & Co., Basel, Switzerland (The Hoffmann-LaRoche Chemical Works, New York). U. S. patent No. 799,764 (Sept. 19, 1905; expires 1922). U. S. trademark No. 59,581.

Thephorin Tablets, 7 1/2 grains: Each tablet contains thephorin 0.5 Gm. (7½ grains).

UROPHERIN-B—Theobrominæ et Lithii Benzoas. — Theobromine and Lithium Benzoate—Uropherin Benzoate.—Uropherin-B is theobromine lithio-benzoate, $LiC_7H_7N_4O_2 + LiC_7H_5O_2$, a double salt of theobromine-lithium and lithium benzoate.

It is a white powder containing 50 per cent. of theobromine. It is soluble in 5 parts of water; it decomposes on exposure to light and air.

A solution of uropherin-B will respond to the various tests for lithium, theobromine and benzoate.

Actions and Uses.—It is a *diuretic, said to be particularly efficient in connection with digitalis.*

It is said to be useful in dropsy, nephritis and diseases of the heart and of the genitourinary organs.

Dosage.—0.3 to 1 Gm. (5 to 15 grains) in powder or capsules, followed by water.

Manufactured by E. Merck, Darmstadt (Merck & Co., New York). U. S. trademark.

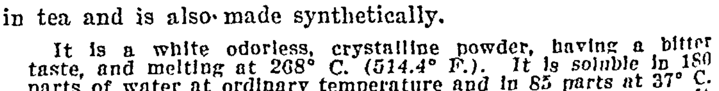
UROPHERIN-S—*Theobrominæ et Lithii Salicylas.*—Theobromine and Lithium Salicylate—Uropherin Salicylate.—*Uropherin-S is theobromine lithio-salicylate*, $LiC_7H_7N_4O_2 + LiC_7H_5O_3$, a double salt of theobromine-lithium and lithium salicylate.

Actions and Uses.—The properties, actions, uses and dosage of this compound are practically the same as those of "theobromine-lithium benzoate" (see Uropherin-B).

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York). U. S. trademark.

THEOPHYLLINE AND THEOPHYLLINE COMPOUNDS.

THEOPHYLLIN—Theophyllina. — 1,3-Dimethyl-Xanthine.—Theophyllin is *1,3-dimethyl-xanthine*,



$$\begin{array}{l} N(CH_3).CO.C.NH \diagdown \\ | \qquad\qquad\quad \| \qquad\qquad CH + H_2O = C_7H_8O_2N_4 + H_2O, \\ CO.N(CH_3).C.N \diagup\!\!\diagup \end{array}$$

an organic base isomeric with theobromine; it is found in small amounts in tea and is also made synthetically.

It is a white odorless, crystalline powder, having a bitter taste, and melting at 268° C. *(514.4° F.). It is soluble in* 180 parts of water at ordinary temperature and in 85 *parts at* 37° C. (98.6° F.), sparingly soluble in alcohol, insoluble in ether. It forms easily soluble compounds with ammonium and potassium, a less soluble salt with sodium, but a freely soluble double salt with sodium acetate.

It responds to the murexid test. Addition of tannin to *a solution* of theophyllin produces a precipitate soluble in *an* excess of the reagent. It is soluble in an excess of sodium hydroxide solution (difference from caffeine). *On addition to solution* of theophyllin in sodium hydroxide of a solution of sulphanilic acid 0.5, hydrochloric acid 5.0, water 100, to which a few drops of a ½ per cent. solution of sodium nitrite *have been* added (diazo test), a red coloration is produced (distinction from caffeine and theobromine).

Actions and Uses.—Theophyllin has a diuretic action similar to that of caffeine *or theobromine* but is more effective. The diuretic effect, however, is not prolonged and its administration is, therefore, advantageously followed by one of the theobromine derivatives having a weaker, but more persistent, action. It occasionally produces gastric disturbances and renal irritation has also been reported. It is claimed that these may be obviated by the use of theophyllin sodio-acetate (which see) instead.

It is used in cardiac affections, nephritis, dropsy, etc.

Dosage.—0.2 to 0.35 Gm. (3 to 5 grains) in warm tea.

Proprietary Preparations:

THEOPHYLLIN (Boehringer) is prepared by transformation of uric acid.

Manufactured by C. F. Boehringer & Soehne, Mannheim, Germany. (Merck & Co., New York.) U. S. patent Nos. 667,381 (Feb. 5, 1901; expires 1918); 757,328; 757,329 (April 12, 1904; expires 1921).

THEOCIN:—A name applied to theophyllin manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). It is prepared by treating the monoformyl derivative of 1-3 dimethyl-4-5-diamido-2-6-dioxypyrimidin with alkalies. The alkaline salts of theophyllin thus produced are transformed into theophyllin by the action of acids.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany. (Farbenfabriken of Elberfeld Co., New York.) U. S. patent No. 716,994 (Dec. 30, 1902; expires 1919). U. S. trademark No. 39,135.

THEOPHYLLIN SODIO-ACETATE—Theophyllinæ sodio-acetas—*Theophyllin sodium-acetate* $C_7H_7N_4O_2Na + CH_3COONa + H_2O$, is a double salt of sodium acetate and 1, 3-dimethylxanthine-sodium (theophyllinsodium).

It is a white crystalline powder, containing about 60 per cent. of anhydrous theocin. It dissolves in about 20 parts of water at 25° C. (77° F.), but is insoluble in alcohol or ether.

Actions and Uses.—It has the diuretic properties of theophyllin reinforced by the diuretic action of sodium acetate, and being more soluble, it is claimed to be more readily absorbed and to be better tolerated than theophyllin.

It is said to be useful in cardiac affections, nephritis, dropsy, etc.

Dosage.—0.2 to 0.35 Gm. (3 to 5 grains), best given after meals.

Proprietary Preparations:

ACET-THEOCIN SODIUM.—A name applied to Theophyllin-Sodio-Acetate.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany. (Farbenfabriken of Elberfeld Co., New York.) U. S. patent *No. 716.994 (Dec. 30, 1902; expires 1919).* U. S. trademark No. 39,135.

Acet-Theophyllin Sodium.—A name applied to Theophyllin-Sodio-Acetate.

Manufactured by C. F. Boehringer & Soehne, Mannheim, Germany (Merck & Co., New York). U. S. patent Nos. 667.381 (Feb. 5, 1901; expires 1918); 757,328; 757,329 (April 12, 1904; expires 1921).

THERMODIN — Phenacetin-Urethane. — Acetylparethoxy-*Phenyl-Urethane.*—Thermodin, $C_6H_4(OC_2H_5).(N(COOC_2H_5)(CH_3CO)) = C_{13}H_{17}O_4N$, is a compound of acetphenetidin (phenacetin) and ethyl carbamate (urethane). It is chemically related to acetphenetidin (phenacetin), but differs from the latter in that it contains the group $[N(COOC_2H_5)(CH_3CO)]$ in place of $(NH.CO.CH_3)$.

It is prepared by the action of ethyl chlorocarbonate on paraphenetidin by which parethoxyphenyl-urethane is formed which is converted into the acetyl compound by heating with acetic anhydride.

It forms colorless, odorless and tasteless crystals, melting at 86° to 88° C. (186.8° to 190.4° F.). It is practically insoluble in cold water (1:2600); soluble in 450 parts of boiling water.

If 0.5 Gm. of thermodin, 5 Cc. sulphuric acid, and 5 Cc. of alcohol are mixed and warmed gently, the odor of ethyl acetate is developed. A solution of 0.5 Gm. of thermodin in 5 Cc. of sulphuric acid on the addition of 0.2 Gm. of sucrose, assumes a red color, becoming more intense on standing (distinction from neurodin). If 0.5 Gm. of thermodin is boiled with 3 Cc. of hydrochloric acid during one minute, then mixed with 5 Cc. phenol solution 1:20, and a solution of chlorinated lime added, an onion red color appears which changes to blue on supersaturation with ammonium hydroxide. 0.1 Gm. of thermodin dissolved in 1 Cc. of sulphuric acid should form an almost colorless solution. 0.1 Gm. of thermodin should, on ignition, not leave a weighable residue.

Actions and Uses.—Thermodin is an analgesic, antipyretic and antiseptic.

It is recommended as a mild and reliable antipyretic in typhoid fever, pneumonia, influenza, tuberculosis and febrile conditions in general, and is said to be free from unpleasant by-effects. There is every *reason to believe, however,* that for use in these infectious diseases it is open to the same objection as the other derivatives of acetphenetidin and related products. (See Acetphenetidin.)

Dosage.—0.3 to 0.6 Gm. (5 to 10 grains) as an antipyretic; 1 to 1.3 Gm. (15 to 20 grains) as an analgesic.

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York). *U. S. trademark.*

THIGENOL.—Solution of Sodium Sulpho-Oleate, Roche.—Thigenol is a *solution* of the sodium salts of synthetic sulpho-oleic acids, containing 2.85 per cent. sulphur.

Precipitated sulphur is dissolved by boiling in the glyceride of oleic acid; the resulting solution is treated with sulphuric acid, during which process sulphurous acid escapes, and a sulpho-oleic acid is separated out. The separated sulpho-acid is then obtained by pouring *into water, and subsequently* washing thoroughly. By treatment with solution of sodium hydroxide, there results a solution of sodium sulpho-oleate, which is evaporated in vacuo until it has a specific gravity of 1.05 to 1.06.

Thigenol is a dark brown liquid, having a faint sulphurous odor. It is soluble in one or more parts of water, dilute alcohol, glycerin, *chloroform, oily or fatty* bases, with any one of which it mixes freely. When water is the vehicle employed, it should be distilled; hard water will cause a precipitate. Thigenol is incompatible with mineral acids or acetic acid.

Actions and Uses.—Thigenol is said to have the actions of sulphur. It is claimed to stimulate granulation, restrict secretions and to be antipruritic.

It is used in diseases of the uterus and its appendages and in skin diseases in which sulphur is commonly employed.

Dosage.—0.2 to 0.6 Gm. (3 to 10 grains) in plain or sweetened water. Thigenol is used locally either in the pure state or mixed in any desired proportion with ointment bases, fats or glycerin according to the intensity of action required.

Manufactured by F. Hoffmann-LaRoche & Co., Basel, Switzerland. (The Hoffmann-LaRoche Chemical Works, New York). U. S. trademark No. 51,393. Not patented.

THIOL.—Thiolum.—Thiol is a water soluble mixture of sulphurated and sulphonated petroleum oils.

Thiol is *prepared* by heating certain *paraffin oils* with 10 per cent. of sulphur, by which a partial addition of the sulphur takes place. The thiol oil thus formed is then treated with sulphuric acid for sulphonization. The excess of sulphuric acid is washed out by water and the sulphonated product neutralized by ammonia and the solution freed by dialysis from all inorganic salts. The dialyzed product evaporated to dryness contains about 12 per cent. of sulphur. For therapeutic purposes the evaporation is not carried to absolute dryness but the product is marketed either in the form of a syrupy liquid (Thiol Liquid, see below) or as a powder (Thiol Dry, see below).

Thiol is a brown powder with a pleasant odor resembling Russia leather, having a somewhat bitter and slightly astringent taste. It swells up in water and finally dissolves. It is also soluble in alcohol and slightly soluble in ether.

Thiol should not markedly redden litmus paper.

Actions and Uses.—Thiol is said to have a drying, astringent, antiphlogistic, and disinfecting action. Taken internally it is said to favor digestion and defecation. It is said to be useful in skin diseases, especially in dermatitis, acne, eczema, erysipelas, erythema, furunculosis, herpes, pruritus, pityriasis, etc. It is also claimed to be useful in burns, in rheumatism and in certain diseases of women.

Dosage.—It may be applied locally in the form of liquid thiol in full strength or in solution with glycerin or water or in the form of ointment or a 2 per cent. solution of liquid thiol may be used as a spray. Internally it may be given in the form of dry thiol in the dose of 0.1 to 0.2 Gm. (1½ to 3 grains) three times a day. Dry thiol may be employed as a dusting powder, either alone or with 80 per cent. of starch or in the form of ointment or of paste.

Manufactured by J. D. Riedel Aktiengesellschaft, Berlin, Germany (Riedel & Co., New York). U S. trademark 16,553.

Thiol Dry.—Thiolum Siccum.—Thiol Dry is a brown powder with properties corresponding to the description of thiol, containing from 8 to 9 per cent. of sulphur.

Actions, Usage and Dosage.—See Thiol.

Thiol Liquid.—Thiolum Liquidum.—Thiol liquid is a preparation of thiol containing about 1.8 to 2 per cent. of sulphur.

It is a dark brown *neutral liquid of a* not unpleasant smell resembling that of Russian leather It is easily soluble in water and glycerin but only slightly soluble in ether.

Actions, Uses and Dosage.—See Thiol.

THIOSINAMINE AND THIOSINAMINE COMPOUNDS.

THIOSINAMINE—Thiosinamina.—Allyl Sulphocarbamide—Allyl Thiourea—Rhodaline.—Thiosinamine is allyl-thio-urea, $(NH_2).CS.NHCH_2.CH:CH_2 = C_4H_8N_2S$.

It is prepared by warming together volatile oil of mustard (chiefly allyl thiocyanate) and alcoholic solution of ammonia, collecting the crystalline product of condensation, and recrystallizing from alcohol.

It forms colorless crystals, having a slight alliaceous odor and bitter taste and melting at 74° C. (165.2° F.). It is moderately soluble in water, but is decomposed by this solvent. It is soluble in about 3 parts of alcohol and readily soluble in ether.

It is incompatible with water, which decomposes it, but this change is to a limited extent prevented by the presence of glycerin.

Actions and Uses.—Thiosinamine appears to cause or quicken the absorption of exudates, lymphatic swellings, scar tissue, etc., the action being unexplained. The opinions as to its value are contradictory.

It is used by hypodermic injection in lupus, chronic glandular tumors, cicatrices, etc. By the mouth in stricture, corneal opacity, chronic deafness.

Dosage.—0.03 to 0.1 Gm. (½ to 1½ grains) in capsules or tablet triturates; in subcutaneous injections, 0.05 to 0.2 Gm. (1 to 5 grains) in 15 per cent. alcoholic or 10 per cent. glycerinated water solution.

SOLUTION THIOSINAMINE SODIUM SALICYLATE.—Liquor Thiosinaminæ Sodio-Salicylatis.—*A sterilized solution containing 15 per cent. of a double salt of thiosinamine and* sodium salicylate, $(NH_2.CS.NHCH_2.CH:CH_2)\ C_6H_4(OH)\ (COONa)$.

It is prepared by mixing the two compounds in solution.

It is an aqueous odorless solution. It does not keep well in the air, but is marketed in sealed, brown glass vials, each containing 2.3 Cc. (37 minims) of the solution, equivalent to 0.2 Gm. (3 grains) of thiosinamine.

The tests are those of thiosinamine and sodium salicylate.

Actions and Uses.—Those of thiosinamine, with the advantage of quicker absorption and freedom from pain or irritation, on account of its solubility and aqueous vehicle.

Dosage.—The contents of one vial (2.3 Cc. = 0.2 Gm. thiosinamin) by *subcutaneous, intramuscular or intravenous* injection; one injection being administered daily or every second or third day.

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York). U. S. *trademark* No. 49,160.

THORIUM NITRATE—*Thorii* Nitras.—Thorium nitrate, $Th\ (NO_3)_4 + 4H_2O$, *is the thorium salt of nitric acid.*

Thorium nitrate occurs as white *crystalline* granules or lumps. Very *soluble* in water and alcohol. On calcination yields a voluminous, white oxide, which should amount to 48-50 per cent. of the original salt. The aqueous solution dries over sulphuric acid to a crystalline mass.

An aqueous *solution gives* a white precipitate with ammonium carbonate, the precipitate being completely soluble in an excess of the precipitant. The aqueous solution gives with caustic alkalies a voluminous precipitate of the hydroxide insoluble in an excess of the precipitant. The presence of *tartaric acid* prevents the precipitation. Potassium ferrocyanide produces an amorphous precipitate.

Action and Uses.—The soluble thorium salts bear a close resemblance to alum in their local astringent and irritant properties. They are not absorbed from the alimentary canal. Hypodermically, they cause local sloughing, and intravenously, they kill by coagulating the blood. The non-precipitant double salts are practically non-toxic, even intravenously. They are excreted by the kidneys. Thorium salts are fairly radioactive. They have been recommended for local application in malignant diseases and thorium emanation has been inhaled in phthisis. Reliable evidence as to the therapeutic value of thorium salts is lacking.

Dosage.—A solution of thorium nitrate (1 to 5) is neutralized with ammonia, and allowed to stand in a bottle four-fifths full; the emanation that accumulates in the vessel is inhaled (Br. Codex).

THYMOL IODIDE.

Thymol Iodide is official in the United States Pharmacopeia. For description see the *pharmacopeia* or the Physicians' Manual of the Pharmacopeia and National Formulary.

ARISTOL.—A name applied to Thymolis Iodidum, U. S. P.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). U. S. *trademark* No. 17,393.

THYRESOL.—Thyresol consists chiefly of the methyl ether of santalol, $C_{15}H_{23}OCH_3$. It is prepared *by the* action of sodium methylate on "santal oil chloride."

Thyresol is *a colorless liquid* of aromatic odor, almost insoluble in water; easily soluble in alcohol and ether; soluble in concentrated sulphuric acid with a reddish-brown color. Boils at 149-156° C. (300.2-312.8° F.) under pressure of about 16 mm. On heating with *hydriodic acid,* santalyl iodide and methyl iodide are formed.

Actions and Uses.—Similar to sandal wood oil, but said to be *practically* free from irritant effects on the stomach and *kidneys.*

It is said to be useful in acute and chronic gonorrhea, anterior and posterior, and other conditions in which the sandal wood oil preparations are indicated.

Dosage.—0.5 Gm. (8 grains) 3 to 4 times daily, best given in milk or gelatin capsules.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany. (Farbenfabriken of Elberfeld Co., New York.) U. S. patent No. 909,541 (Jan. 12, 1909; expires 1926).

THYROID PREPARATIONS.

IODOTHYRINE—*Thyroiodine.*—*Iodothyrine* is a milk sugar *trituration of the active principle of thyroid gland,* 1 Gm. representing 1 Gm. of fresh gland and containing 0.0003 Gm. of iodine.

According to the patent specifications iodothyrine may be obtained by boiling the *fresh thyroid glands, freed from fat, with* dilute sulphuric *acid, cooling the liquid and collecting the body* which separates, dissolving the active portion in alcohol and evaporating to dryness. The product is further purified by washing with ether, which dissolves impurities. One part of the active ingredient is mixed with *309 parts of* sugar of milk.

It is a white or yellowish white powder, having the sweet taste of milk sugar.

Actions and Uses.—It is similar in action to Glandulæ Thyroideæ *Siccæ,* U. S. P., *but it is claimed to possess* the advantage *of more definite strength and absence of decomposable* extraneous matter.

Dosage.—Adults, 0.6 to 2 Gm. (10 to 30 grains); children, 0.3 to 1 Gm. (5 to 15 grains) per day.

Manufactured by Farbenfabriken, vorm. Friedr. Bayer & Co., Elberfeld, Germany (Farbenfabriken of Elberfeld Co., New York). E. Merck, *Darmstadt* (Merck & Co., New York). *U. S. patent* No. 626,648 (June 6, 1899; expires 1916). U. S. trademark No. 29,406.

Iodothyrine Tablets, 5 grains. Each tablet contains iodothyrine 0.33 Gm. (5 grains).

TRIFERRIN—Triferrinum.—Triferrin is ferric paranucleinate; *a compound* of caseinparanucleinic acid with iron, containing 22 per cent. of iron, 9 per cent. of nitrogen and 2.5 per cent. of *phosphorus in natural (organic) combination.*

It is prepared by digesting cow's milk-casein with pepsin and precipitating the solution with a *ferric* salt.

It is a tasteless powder. It is soluble in weak solution of sodium hydroxide, but insoluble in weak hydrochloric acid (0.1 to 0.3 per cent.).

Actions and Uses.—In addition to its hematinic action derived from the iron, it is claimed to act like lecithin by reason of the phosphorus in organic combination which it contains. It is said to agree with very sensitive stomachs, since it *passes* the stomach unchanged but is freely absorbed in the intestines.

It is said to be useful in anemia, chlorosis, neurasthenia, rachitis and general *debility.*

Dosage.—0.3 Gm. (5 grains) in powder, taken during meals.

Manufactured by Knoll & Co., Ludwigshafen a. Rh., Germany, and New York (Knoll & Co., New York). German patent No. 114,-273. U. S. trademark No. 36,747.

Triferrol—*Liquor* Triferrini, Knoll.—Triferrol is an elixir of triferrin, said to contain 0.06 Gm. (1 grain) triferrin in 4 Cc. (1 fluidram). It contains 15 per cent. of alcohol.

A soluble form of *triferrin (soluble triferrin* Knoll), is dissolved in *a vehicle consisting of* water, alcohol, tincture of orange, tinct. cardamon co. and vanillin.

Dosage.—16 Cc. (4 fluidrams) corresponding to 0.24 Gm. (4 grains) of the powder.

TRIOXYMETHYLENE — **Paraformaldehydum.**—Paraformaldehyde.—Trioxymethylene, $(CH_2O)x$, is a polymeric condensation of formaldehyde.

It is prepared by concentrating an aqueous solution (40 per cent.) of *formaldehyde* by evaporation.

It is a white, crystalline powder, melting at 171° C. (339.8° F.). It is insoluble in alcohol or ether, but slowly soluble in water at ordinary *temperature,* more rapidly when heated, formaldehyde being regenerated as indicated by the vapors given off.

It responds to the tests for formaldehyde.

It has the same incompatibilities as *formaldehyde:* Bases, oxidizing agents, gelatin, tannin, etc.

Actions and Uses.—Antiseptic and escharotic. Externally it is used chiefly to generate formaldehyde by heating, for disinfection or for inhalations.

Dosage.—Internally, 0.3 to 1 Gm. (5 to 15 grains); externally (for warts), in 10 per cent. suspension in collodion.

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York). It is not patented or trademarked.

TRIPHENIN.—Propionyl-Phenetidin—Triphenin, $C_6H_4(OC_2H_5)NH(CH_3CH_2CO) = C_{11}H_{15}NO_2$, is a derivative of paraphenetidin, differing from acetphenetidin (phenacetin), $C_6H_4(OC_2H_5)NH(CH_3CO)$, in that the acetic acid residue, $(CH_3.CO)$, has been replaced by the propanoic acid residue, $(CH_3.CH_2.CO)$.

It is a white, shining, crystalline powder, melting at 120° C. (248° F.), odorless and faintly bitter. It is practically insoluble *in water, requiring 2,000 parts, but* soluble in alcohol and in ether.

It is prepared by heating paraphenetidin with propanoic acid
oduct.
s to the pharmacopoeial tests for acet-
From this it may be distinguished by
y identifying the propanoic acid evolved
when heated with 50 per cent. sulphuric acid.

Its incompatibilities are those of acetphenetidin (phenacetin.)

Actions and Uses.—Triphenin is antipyretic, analgesic and hypnotic, its action is slower and milder than that of phenacetin, because it is less soluble, and it is said to be free from by- or after-effects.

It has been recommended in typhoid, pneumonia, pleurisy, influenza, erysipelas and tuberculosis; also in neuralgia, sciatica, migraine, tabetic pains, etc. Like similar products, it must be used with caution, especially in the infectious fevers. (See Acetphenetidin.)

Dosage.—As an antipyretic, 0.25 to 0.6 Gm. (4 to 10) grains); as an antineuralgic, 1 to 1.3 Gm. (15 to 20 grains), preferably in wafers.

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York). *U. S. patent* No. 535,846 (March 19, 1895; expires 1912). U. S. trademark.

TROPACOCAINE HYDROCHLORIDE—Tropacocainæ Hydrochloridum.—Benzoylpseudotropeine Hydrochloride—Tropeine.—Tropacocaine hydrochloride, $C_8H_{14}NO(C_7H_5O.)HCl = C_{15}H_{19}NO_2.HCl$. is the hydrochloride of synthetic tropacocaine.

Pseudotropin-Lieberman is obtained from tropinon or from tropin by electrolytic reduction and *from this the benzoyl* derivative is obtained and this is converted to the hydrochloride.

It forms colorless, needle-shaped crystals, melting at 271° C. (519.8° F.). It is readily soluble in water, and its solution keeps well for several months. Heated in the presence of hydrochloric acid it is split into benzoic acid and tropine.

Its incompatibilities are the same as those of the alkaloids in general.

Actions and Uses.—Tropacocaine hydrochloride is a local anesthetic, resembling *cocaine very closely* in its general action, but only half as poisonous. It is reported that anesthesia sets in more rapidly and lasts longer than with cocaine. It produces less dilatation of the pupil, sometimes none at all. It is employed as a local anesthetic.

Dosage.—It is applied in 3 to 10 per cent. aqueous solutions containing 0.6 per cent. sodium chloride.

Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York). U. S. patent No. 628,293 (*July* 4, 1899; expires 1916).

UREA.—Urea, $CO(NH_2)_2 = CH_4ON_2$, is the diamide of carbonic acid.

Urea occurs as colorless transparent prismatic crystals almost odorless having a cooling *saline taste. It* is somewhat hygroscopic. It is soluble in water (1-1), more readily *in hot water. Soluble in alcohol (1-7) and (1-1)* in boiling alcohol. It is insoluble in ether and chloroform. *It fuses* at 132° C. (269.6° F.), evolving ammonia and ammonium cyanate. Kept at 150° C. (302° F.) for some time most of it is converted to biuret. If the temperature is raised to 170° C. (338° F.) the biuret evolves ammonia and is converted to cyanuric acid. Heated with water under pressure it is *decomposed into* ammonium carbonate. It is not alkaline, but is a weak base and though a diamide, forms salts like a *monacid* base; *these are acid to litmus. By hydrolysis it is* converted into ammonia and carbon dioxide. Nitric and oxalic acids produce precipitates when added to concentrated solutions of urea.

Action and Uses.—Urea is an active diuretic; it is rapidly eliminated and is not poisonous. It has been claimed, without convincing proof, to have the power of dissolving urinary calculi. It has been recommended in the treatment of tuberculosis, but this use of it is *generally* being abandoned. It may be employed where diuresis is indicated, though it appears irrational in primary renal disease.

Dosage.—0.5 to 4 Gms. (10 to 60 grains). Urea is given in solution, or *it* may be enclosed in cachets.

VALIDOL.—Validol is menthyl valerianate, $C_{10}H_{19}O.C_5H_9O$, the menthylester of valerianic acid, with 30 per cent. of free menthol.

It is prepared by heating a mixture of 16 parts of menthol and 12 parts of valerylchloride on a water bath until hydrogen chloride ceases to be given off, adding very dilute solution of sodium hydroxide, shaking out the mixture with ether, drying the ether-solution with potassium carbonate, distilling off the ether, *and rectifying the residual oily product* by vacuum distillation, finally dissolving 30 per cent. of free menthol in the pure ester so obtained.

Validol is a crystal-clear, colorless liquid, of the consistency of glycerin, having a mild and pleasant odor, distinct from either that of menthol or valerian, and a refreshing cool and very faintly bitter taste, insoluble in water, but readily soluble in alcohol, ether, chloroform, and oils. It is decomposed by alkalies. On warming with sodium hydroxide solution, the odor of menthol manifests itself; if then the alkaline solution is acidulated with diluted sulphuric acid, the odor of valerianic acid is developed. It is incompatible with alkaline media.

Actions and Uses.—Analeptic, antihysteric, carminative, stomachic; combining the activity of valerianic acid and of menthol. It is devoid of the irritating acridity of the latter and is said to be well tolerated by the most sensitive stomach.

It is said to be useful in hysteria, migraine, gastralgia, gastritis, vomiting of pregnancy, exhaustion, hypochondria, syncope and certain reflex neuroses.

Dosage.—10 to 15 drops, on sugar, or in a little sweet wine.

Manufactured by Vereinigte Chininfabriken, Zimmer & Co., Frankfort a. M., Germany (C. Bischoff & Co., New York).

VALIDOL CAMPHORATUM.—Validol camphoratum is camphorated Validol.

Camphorated Validol is a 10 per cent. solution of camphor in validol. Camphorated Validol is a clear, colorless liquid, of the consistency of glycerin, having an agreeable odor, and *refreshingly* cool and faintly bitter taste. It is insoluble in water, but readily soluble in alcohol, oils and other organic solvents. It is incompatible with alkaline media.

Actions and Uses.—Restorative, local analgesic, non-irritant and non-poisonous; well tolerated by the mucous membrane of the stomach. It is said to be useful in serious cases of exhaustion, where the administration of camphor is indicated; in odontalgia, either by application to the pulp or inserted on cotton into the previously rinsed cavity.

Dosage.—10 to 15 drops, on sugar or in wine.

Manufactured by Vereinigte Chininfabriken, Zimmer & Co., Frankfort a. M., Germany (C. Bischoff & Co., New York).

VALYL.—Valeryldiethylamidum.—Valerianic Acid Diethylamide.—Valyl is valeryl diethylamide, $C_4H_9CO.N(C_2H_5)_2 = C_9H_{19}ON$, a compound of valeric acid and diethylamine.

It is prepared by the direct interaction of its acid and basic components.

It is a bright, colorless, neutral liquid, having a peculiar pepper-like odor, boiling at 210° C. (410° F.). It is soluble in 25 parts of water and easily soluble *in alcohol* or ether.

It should be neutral to moistened litmus paper and the boiling point should not vary materially above or below that indicated.

It should not be exposed to the air.

Actions and Uses.—Valyl acts as a sedative, antispasmodic and nervine, similar to valerian.

It is said to be useful in hysteria, traumatic neurosis, hemicrania, neuralgia, menstrual irregularities, insomnia due to nervousness, etc.

Dosage.—Owing to the liability of valyl to oxidize when exposed to the air, it is supplied only in the form of pearls, each containing 0.125 Gm. (2 grains), the dose being 2 or 3 capsules, administered during or immediately after meals, or otherwise with a little milk.

Manufactured by Farbwerke, vorm. Meister, Lucius & Bruening, Hoecht a. M., *Germany* (Victor Koechl & Co., New York). U. S. patent No. 697,730 (April 15, 1902; expires 1919).

VIOFORM. — Iodochloroxyquinolin. — Nioform. — Vioform is iodo-chlor-hydroxy-quinoline, $C_9H_4N.OH.I.Cl = C_9H_5ONClI$, a substitution compound of anachlor-orthohydroxy-quinoline, resulting from the introduction of one atom of iodine.

Hydroxy-quinoline is first chlorinated and dissolved in an alkaline solution, which is then *treated* with a solution of iodine in potassium iodide when a voluminous yellowish brown precipitate of vioform is produced. *This is washed* with a solution of sodium thiosulphate to remove free *iodine* and then with 1 per cent. hydrochloric acid until the dried residue melts at from 170° to 175° C. (338° to 347° F.).

It is a very voluminous, greenish yellow powder; crystallizing from glacial acetic acid in needles melting at 177° to 178° C. (350.6° to 352.4° F.), practically odorless, and insoluble in water and slightly soluble in alcohol; *it permits* sterilization without
s as bulky as iodoform.

Vioform contains 41.57 per cent. of iodine—it gives a green coloration with Millon's reagent or when the alcoholic solution is treated with ferric chloride solution. It dissolves with a brown color in concentrated sulphuric acid and the solution evolves iodine on warming. If this solution, after driving off the iodine, be diluted with water, chlorine can be demonstrated by the usual test with silver nitrate. If a solution of vioform *in chloroform is shaken with nitric acid, the chloroform acquires* a violet red color, and the nitric acid becomes somewhat yellow.

Actions and Uses.—It is antiseptic, hemostatic, cicatrisant; non-toxic and non-irritant. It is claimed to be an ideal substitute for iodoform and to prevent decomposition in wound secretions to a much higher degree. Drains and tampons may be left *in situ* for a considerable time.

Dosage.—As a dusting powder and as an ointment spray, suppository, or in form of gauze.

Manufactured by Baseler Chemische Fabrik, Basel, Switzerland (C. Bischoff & Co., New York). German patent No. 117,767.

Vioform Gauze.—Gauze impregnated with a solution of 10 Gm. (150 grains) of vioform, 50 Gm. (750 grains) of absolute alcohol, 10 Gm. (150 grains) of sugar, 25 Gm. (375 grains) of glycerin, and 500 Gm. (1 1/12 pints) of water.

XEROFORM—Bismuthi Tribromphenolas.—Tribromphenol-Bismuth.—Xeroform is basic bismuth tribrom-phenolate, $Bi(C_6H_2Br_3O)_2OH.Bi_2O_3 = C_{12}H_5O_6Br_6Bi_3$, *containing nearly 50 per* cent. of Bi_2O_3.

According to the patent it is *obtained by dissolving* tribromphenol in sodium hydroxide and adding bismuth nitrate to the sodium tribromphenolate solution. The precipitated tribromphenol bismuth is collected, and washed with alcohol.

It is a fine yellow, nearly odorless and tasteless powder, neutral in reaction, *and unaffected by light. It is insoluble in* water, alcohol, chloroform, liquid petrolatum and vegetable oils, but soluble in 2 per cent. hydrochloric acid in the proportion of 30:100. By alkalies it is decomposed with the formation of bromides; it is not decomposed by heat at temperatures below 120° C. (248° F.), and therefore may be sterilized.

It should yield 49.5 per cent. of bismuth oxide. If 1 Gm. is boiled with sodium hydroxide T. S. filtered, the filtrate rendered *acid* with sulphuric acid and the white, curdy precipitate washed and dried, it should melt at 95° C. (203° F.) (tribromphenol).

It is incompatible with alkaline media and should not be heated above 120° C. (248° F.).

Actions and Uses.—Xeroform is claimed to be non-irritant and non-toxic antiseptic. It is said to be useful as an odorless and efficient substitute for iodoform; as valuable in *ulcus cruris* and all weeping eczemas; internally, in gastrointestinal catarrh, proctitis, dysentery, bacillary and choleraic diarrhea, cholera infantum, etc. (See note under Creosote Carbonate.)

Dosage.—1 to 3 Gm. (15 to 45 grains) per day to adults; 0.12 to 0.3 Gm. (2 to 5 grains) at a dose to children. Externally, as a dusting powder, in bandages, etc., like iodoform.

Manufactured by the Heyden Chemical Works, New York. U. S. patent No. 516,358 (March 13, 1894; expires 1911).

ZINC PERMANGANATE.—Zinci Permanganas.—Zinc permanganate, $Zn\ (Mno_4)_2 + 6H_2O$ is the zinc salt of permanganic acid. It should contain *not less than 90* per cent. *of zinc* permanganate.

Zinc permanganate occurs in dark brown, nearly black, lustrous deliquescent crystals, or crystalline masses. It is readily soluble in water (1 in 3), generally leaving a slight residue. Aqueous solutions decompose in air, but are permanent if kept in well-closed bottles, protected from light. When heated slowly it loses water of crystallization *(25.46 per cent.) and oxygen*, leaving a residue of zinc manganite. If heated quickly it gives off pink vapors, or more properly, a fine dust of manganese trioxid. Zinc permanganate gives up oxygen more easily than does the potassium salt, hence great care should be taken in bringing it in contact with easily oxidizable substances.

Zinc permanganate should be almost completely soluble in water. The color of the solution is discharged by alcohol, hydrogen sulphid, ferrous *sulphate*, *oxalic acid*, or hydrogen dioxid, especially if the solution is first rendered acid with sulphuric acid

Tests.—If 1 Gm. of the *salt is dissolved* in 50 Cc. of water and 5 Cc. of alcohol added, a colorless solution must be obtained after boiling and filtering; if a small part of the latter acidified with nitric acid is tested with silver nitrate T. S. for chlorid and with barium chlorid T. S. for sulphate, not more than traces of either should be indicated.

To estimate *its purity, 0.1 to 0.2 Gm. of* substance is weighed, dissolved in water, filtered through asbestos, the filtrate acidulated with 5 Cc. dilute sulphuric acid, warmed to about 60° C., treated with an excess of tenth-normal oxalic acid V. S., *and* the excess of oxalic acid determined by titration with N/10 potassium permanganate V. S. Each cubic centimeter of tenth-normal oxalic acid V. S. consumed indicates 0.0040842 Gm. zinc permanganate, $Zn(MnO_4)_2 + 6.H_2O = 408.42$.

Action and Uses.—Zinc permanganate resembles the potas*sium* salt in its oxidizing properties, but is more astringent. It is antiseptic. It is used chiefly in urethritis, either as an *injection* or as a urethral douche.

Dosage.—Locally 1 part to 4,000 (1 grain in 8 fluidounces). 1.3 Gm. zinc permanganate is equal in permanganate content to 1 Gm. potassium permanganate.

Non-Proprietary Preparations:

Zinc Permanganate, P-W-R.—Manufactured by the Powers-Weightman-Rosengarten Co., Philadelphia, Pa.

Zinc Permanganate, Merck.—Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York).

Tablets Zinc Permanganate, 1 grain, Mulford.—Each tablet contains zinc permanganate 0.065 Gm. (1 grain). Prepared by the H. K. Mulford Co., Philadelphia, Pa.

'Soloid' Zinc Permanganate, 1/8 grain, B.-W. & Co.—Each tablet contains zinc permanganate 0.008 Gm. (⅛ grain). Prepared by Burroughs-Wellcome & Co., London and New York.

ZINC PEROXIDE—Zinci Peroxidum.—Zinc Peroxide is the zinc salt, ZnO_2, of hydrogen peroxide, containing an admixture of not more than 55 per cent. of zinc oxide.

Zinc peroxide occurs as a yellowish white voluminous powder; *tasteless*, *odorless*, *non-hydroscopic*, *antiseptic*, neither caustic nor irritant, and not more toxic than ordinary zinc oxide. It is insoluble in water, but gives to it a slight alkaline reaction; it is soluble in cold dilute sulphuric acid with evolution of oxygen and in dilute hydrochloric acid with liberation of chlorine. It gives all the reactions of peroxides, caramelizes sugar, disengages oxygen by the action of acids and in contact with living tissue. It is stable in the autoclave to 130° C. and at a dry heat to 150° C., *and thus may be readily sterilized. Heated to higher* temperature, it loses oxygen and forms zinc oxide. It should not respond to tests for calcium, magnesium, barium, sulphates, chlorides or carbonates.

0.2-0.3 Gm. zinc peroxide accurately weighed and added to 50 Cc. water and acidulated with 20 Cc. dilute sulphuric acid, should *require* for each 0.1 Gm. material used not less than 9.25 Cc. dilute tenth-normal permanganate solution to produce a permanent pink color.

Action and Uses.—Zinc peroxide is used in the extemporaneous preparation of hydrogen peroxide for wounds, chronic ulcers, etc. It may be applied as a dressing directly on wounds, etc., where it produces hydrogen peroxide *in situ*. For eczema and other skin diseases it is sometimes prescribed with half its weight of potassium iodide and *one-tenth* its weight of tartaric acid, the mixture liberating iodine on contact with moist surfaces.

Dosage.—It may be used as a dusting powder either alone or mixed with tannin, or in the form of gauze, or a 10 per cent. ointment.

Proprietary Preparation:

PEROXIDE ZINC SOAP—Sapo cum zinci peroxido.—Peroxide Zinc Soap is a soap containing 10 per cent. zinc peroxide, which see.

Actions and Uses.—It is said to be useful as a vehicle for employing zinc peroxide *in the treatment of skin diseases*.

Prepared by J. Eavenson & Sons, Camden, N. J., for the Roessler & Hasslacher Chemical Co., New York. U. S. patent No. 787,776 (April 18, 1905; expires 1922). No trademark.

APPENDIX.

An index to the proprietary articles, arranged under the names of the manufacturers or their agents, which, so far as known to the Council, comply with the rules, but which did *not possess sufficient originality* to be admitted to the body of the book (see Introduction to Official Rules of the Council, page 9).

Edward G. Binz Co., Los Angeles, Cal.

Eucaloids.—Gelatine capsules, each said to contain pure *oil of* eucalyptus 0.3 Cc. (5 minims).

Euca-Mul.—An emulsion of oil of eucalyptus in glycerin and honey, said to contain oil of eucalyptus 3.25 Cc. in 100 Cc. (15 minims in a fluid ounce).

Burroughs, Wellcome & Co., New York.

Enule Soap Compound.—A cocoa butter suppository weighing 2.52 Gm. (39 grains) and containing in each suppository curd soap and dry sodium sulphate 0.454 Gm. (7 grains) of each.

Tabloid Hypophosphites Comp.—Each tablet is said to contain: Sodium hypophosphite, 0.0084 Gm. (⅛ grain); potassium hypophosphite, 0.0084 Gm. (⅛ grain); iron hypophosphite, 0.0084 [illegible] hypophosphite, 0.0042 Gm. (1/16 [illegible] 0.0021 Gm. (1/32 grain); strych[illegible] m. (1/128 grain); calcium hypo[illegible] grain).

*Tabloid Coffee Mint.**—Each tablet said to contain: Sodium bicarbonate, 0.2 Gm. (3 grains); ammonium carbonate, 0.004 Gm.

---

* This article and all others thus starred do not comply with the present rules of the Council. Having been accepted before the revision of the rules the Council decided to retain them for the present in the appendix.

(1/16 grain); extract of coffee (obtained by extracting roasted coffee with water, the percolate being evaporated, dried and powdered), 0.032 Gm. (½ grain); cerium oxalate, 0.016 Gm. (¼ grain); oil of peppermint to flavor.

G. W. Carnrick Co., New York.

*Antithermoline.**—Each 1000 Gm. is said to contain purified kaolin, 563 Gm.; boric acid, 2 Gm.; oil of eucalyptus, menthol and thymol, combined, 2 Gm.; and glycerine, 320 Cc. It closely resembles Cataplasma Kaolini, U. S. P.

Cloftlin Chemical Co., New York.

*Emulsion Cloftlin.**—Each 100 Cc. is said to contain calcium hypophosphite, 1.33 Gm. (6 grains in a fluidounce); manganese hypophosphite, 0.66 Gm. (3 grains in a fluidounce); glycerin, 10 per cent.; cod liver oil, 50 per cent. (by volume).

Eusoma Pharmaceutical Co., Cincinnati, O.

Mercuran.—It is stated to be a 50 per cent. mercurial ointment in which the benzoinated lard of the official ointment (Unguentum Hydrargyri U. S. P.) has been replaced by goose fat stearin. It is supplied in capsules containing about 4 Gm. (60 grains) each.

Louisville Pharmacal Works, Louisville, Ky.

Elixir Duozyma.—Elixir Pepsin, Diastase and Hydrastis, L. P. W. A mixture said to represent in each 100 Cc.: pure scale pepsin (1:3000) 2.2 Gm. (10 grains in a fluidounce); malt diastase 0.22 Gm. (1 grain in a fluidounce); golden seal 0.22 Gm. (1 grain in a fluidounce); glycerin, C. P., 10 Cc. (48 minims in a fluidounce) and alcohol 15 per cent.

Malt-Diastase Co., New York.

Maltzyme.—A preparation essentially equivalent to Extractum Malti U. S. P. and containing 7 per cent. of alcohol. U. S. trademark No. 46,459.

Maltzyme with Cod Liver Oil.—Said to consist of maltzyme concentrated and brought back to its original volume by the addition of 25 per cent. of Lofoten cod liver oil.

Maltzyme with Cascara Sagrada.—Each 100 Cc. is said to represent cascara bark, 10 Gm. (48 grains in a fluidounce).

Maltzyme with Hypophosphites.—Each 100 Cc. is said to contain calcium, sodium, and potassium hypophosphites, of each 0.4 Gm. (2 grains in a fluidounce) and iron and manganese hypophosphites, of each, 0.05 Gm. (¼ grain in a fluidounce).

Maltzyme with Phosphate of Iron, Quinine and Strychnine.—Each 100 Cc. is said to contain iron pyrophosphate, 0.85 Gm. (4 grains in a fluidounce); quinine, 0.20 Gm. (1 grain in a fluidounce); strychnine, 0.0066 Gm. (2/75 of a grain in a fluidounce).

Maltzyme Ferrated.—Each 100 Cc. is said to contain iron pyrophosphate, 1.65 Gm. (8 grains in a fluidounce).

Maltzyme with Yerba Santa.—Each 100 Cc. is said to represent yerba santa leaves, 6.6 Gm. (30 grains in a fluidounce).

The Maltine Company, Brooklyn, N. Y.

Maltine.—A preparation essentially equivalent to Extractum Malti U. S. P. and containing 3.88 per cent. alcohol. U. S. trademark No. 44,536.

Maltine with Cascara Sagrada.—Each 100 Cc. is said to represent casgara sagrada (Rhamnus Purshiana) 12.5 Gm. (60 grains in a fluidounce) in a mixture containing maltine 96.115 per cent. and alcohol 3.885 per cent.

Maltine with Cod Liver Oil.—A liquid said to represent maltine, 56.115 per cent.; glycerin, 10 per cent.; cod liver oil, 30 per cent.; alcohol, 3.885 per cent.

Maltine with Creosote.—Each 100 Cc. is said to represent beechwood creosote, 0.83 Cc. (4 minims in a fluidounce) in a mixture containing maltine, 96.115 per cent., and alcohol, 3.885 per cent.

Maltine Ferrated.—Each 100 Cc. is said to represent iron pyrophosphate 1.65 Gm. (8 grains in a fluidounce) in a menstruum containing maltine, 96.115 per cent., and alcohol, 3.885 per cent.

Maltine with Hypophosphites.—Each 100 Cc. is said to contain calcium hypophosphite, 0.64 Gm. (3 grains in a fluidounce), sodium hypophosphite, 0.64 Gm. (3 grains in a fluidounce), and iron hypophosphite, 0.42 Gm. (2 grains in a fluidounce), dissolved in a solution of ammonium citrate and to contain maltine, 96.115 per cent., and alcohol, 3.885 per cent.

Maltine with Olive Oil and Hypophosphites.—A preparation said to consist of maltine, 65 per cent.; pure olive oil, 25 per cent.; glycerin, 10 per cent.; to which per 100 Cc. there is added calcium hypophosphite, 0.6 Gm. (3 grains per fluidounce); sodium hypophosphite, 0.6 Gm. (3 grains per fluidounce).

Maltine with Phosphate of Iron, Quinia and Strychnia.—Each 100 Cc. is said to represent iron pyrophosphate, 0.83 Gm. (4 grains in a fluidounce); quinine sulphate, 0.21 Gm. (1 grain in a fluidounce); strychnine (alkaloid), 0.0066 Gm. (2/75 grain in a fluidounce) dissolved in a solution of ammonium citrate and to contain maltine, 96.115 per cent., and alcohol, 3.885 per cent.

Maltine with Wine of Pepsin.—A liquid said to consist of maltine, 27.5 per cent.; wine of pepsin, 71.5 per cent.; and fluid extract of gentian, 1 per cent., the percentage of alcohol in the mixture being 18 per cent.

Malto-Yerbine.—A liquid said to contain in each 100 Cc. an extract of 6.6 Gm. (30 grains in a fluidounce) of eriodictyon (Yerba Santa), also flavoring composed of the essential oils of anise, cassia, coriander and caraway in a mixture containing maltine, 96.115 per cent. and alcohol, 3.885 per cent.

The extract of Yerba Santa employed in Malto-Yerbine is prepared as follows:

The leaves of Yerba Santa in coarse powder are boiled under pressure for six hours and inert matter separated by a filter press. The filtrate is concentrated with a certain quantity of maltine at a high temperature until the product has reached a density of 1.35. This extract is mixed in proper proportions with maltine of extra diastasic strength to make up for the diastasic strength lost through heat during the concentration of the drug with maltine.

Manhattan Eye Salve Co., Owensboro, Ky.

Argyrol Ointment (M. E. S. Co.)—An ointment said to consist of argyrol 10 per cent.; hydrous wool fat, 25 per cent.; white petrolatum, 65 per cent. Put up in collapsible tubes, for application to the eye.

Compound Yellow Oxide and Adrenalin Ointment (M. E. S. Co.)—An ointment said to contain yellow oxide of mercury 1 per cent., solution of adrenalin chloride 5 per cent., menthol 0.04 per cent., phenol 0.2 per cent., hydrous wool fat 25 per cent., white petrolatum sufficient to make 100 per cent. Put up in collapsible tubes, for application to the eye.

Cocaine and Adrenalin Ointment (M. E. S. Co.)—An ointment said to contain cocaine hydrochloride 2 per cent., solution of adrenalin chloride 17 per cent., hydrous wool fat 25 per cent., white petrolatum sufficient to make 100 per cent. Put up in collapsible tubes, for application to the eye.

Dionin Ointment (M. E. S. Co.).—An ointment said to consist of dionin 5 per cent.; white petrolatum, 95 per cent. Put up in collapsible tubes, for application to the eye.

Holocain and Adrenalin Ointment (M. E. S. Co.).—An ointment said to consist of holocain 1 per cent.; adrenalin chloride, 4 per cent.; hydrous wool fat, 10 per cent.; white petrolatum, 85 per cent. Put up in collapsible tubes for application to the eye.

Wm. S. Merrell Chemical Co., Cincinnati, O.

*Akaralgia.**—A mixture each 100 Cc. of which is said to represent sodium sulphate, 25 Gm.; sodium salicylate, 8.33 Gm.; magnesium sulphate, 42.5 Gm.; lithium benzoate, 4.16 Gm.; tincture of nux vomica, 5 Cc. Each average dose of 2 drams is said to represent sodium sulphate 30 grains, sodium salicylate (Merrell) 10 grains, magnesium sulphate 50 grains, lithium benzoate 5 grains and tincture of nux vomica 6 minims.

Erpiol—Dr. Shrader.—Capsules stated to contain in each: Apiol, green (see Oleoresin of Parsley Seed), 0.31 Cc. (5 minims); Ergotin, Bonjean's process (see Purified Extract of Ergot), 0.065 Gm. (1 grain); Gossypin, resinoid, 0.195 Gm. (3 grains).

H. K. Mulford Co., Philadelphia, Pa.

*Blandine Comp.**—A liquid said to contain in each 100 Cc.: Camphor, 0.3 Gm. (1⅓ grains in a fluidounce); menthol, 0.04 Gm. (1/5 grain in a fluidounce); thymol, 0.04 Gm. (1/5 grain in a fluidounce); eucalyptol, 0.08 Gm. (2/5 grain in a fluidounce); oil of gaultheria, 0.33 Cc. (1½ minims in a fluidounce); hydrastine alkaloid, 0.005 Gm. (1/40 grain in a fluidounce) in a neutral, odorless mineral oil (liquid petroleum). U. S. trademark No. 51,647.

*Casca-Laxative.**—A liquid extract representing in each 100 Cc.: Cascara sagrada, 116.6 Gm. (540 grains in a fluidounce); senna, 58.3 Gm. (270 grains in a fluidounce); podophyllin, 0.16 Gm. (¾ grain in a fluidounce); in a menstruum containing 17 per cent. of absolute alcohol by volume with aromatics.

Compound Capsules of Glycerophosphates. Capsula glycerophosphatum composita.—Each capsule is said to contain: Terebene, 0.2 Cc. (3 minims); oil of sandalwood, 0.2 Cc. (3 minims); guaiacol, 0.06 Cc. (1 minim) calcium glycerophosphate 0.06 Gm. (1 grain) sodium glycerophosphate, 0.03 Gm. (½ grain); strychnine 0.00065 Gm. (1/100 grain); pure olive oil sufficient to make 10 minims.

They are soft, oval shaped capsules of a clear, yellow color, with a small compressed tablet containing the glycerophosphates and strychnine suspended in the oils.

Methyl-Santal.—Each capsule is said to contain: Methylene blue, 0.06 Gm. (1 grain); oleoresin of copaiba, 0.1 Cc. (1 3/5 minims); oleoresin of cubebs, 0.025 Cc. (2/5 minim); oil of sandalwood, 0.09 Cc. (1½ minims); oil of cinnamon, 0.013 Cc. (1/5 minim); oil of nutmeg, 0.005 Cc. (1/12 minim).

Granular Effervescent Sodium Sulphate (Glauber's Salt), Mulford.—A mixture said to contain in each 100 Gm.: Dried sodium sulphate, 40 Gm., with an effervescing mixture consisting of sodium bicarbonate, citric acid, tartaric acid, and sugar. Each heaping teaspoonful weighing about 75 grains is said to contain dried sodium sulphate, 30 grains.

Granular Effervescent Bromide and Acetanilide Compound, Mulford.—A mixture said to contain in each 100 Gm.: Sodium bromide, 5 Gm., acetanilide, 1.5 Gm., and saccharin, 0.014 Gm., with an effervescent base consisting of sodium bicarbonate, and citric and tartaric acids. Each heaping teaspoonful of this salt, about 100 grains, is said to contain about 1.5 grains acetanilide, about 5 grains sodium bromide, and about 1/70 grain of saccharin.

Granular Effervescent Caffeine and Sodium Bromide Compound, Mulford.—A mixture said to contain in each 100 Gm.: Sodium bromide, 5.45 Gm.; caffeine, 0.545 Gm.; and saccharin, 0.014 Gm., with an effervescent base consisting of sodium [illegible] citric and tartaric acids. Each heaping [illegible] about 92 grains, is said to contain about 5 [illegible] ½ grain, caffeine, and about 1/70 grain of saccharin.

Granular Effervescent Caffeine and Potassium Bromide, Mulford.—A mixture said to contain in each 100 Gm.: Potassium bromide, 2.3 Gm.; caffeine, 0.122 Gm.; and saccharin, 0.014 Gm., with an effervescent mixture consisting of sodium bicarbonate, and citric and tartaric acids. Each ounce is said to contain about 10 grains of potassium bromide, about 2 grains of caffeine, and about 1/16 grain of saccharin.

Granular Effervescent Carlsbad Salt (Artificial), Mulford.—A mixture said to contain in each 100 Gm.: Potassium sulphate, 0.35 Gm.; sodium chloride, 3.266 Gm.; sodium bicarbonate, 6.533 Gm., and sodium sulphate (dried), 8 Gm., with an effervescent base consisting of sodium bicarbonate, and citric and tartaric acids. Each heaping teaspoonful of the salt, about 90 grains, is said to contain about ⅓ grain of potassium sulphate, 3 grains of sodium chloride, 6 grains of sodium bicarbonate and 7 grains of sodium sulphate (dried).

Granular Effervescent Carlsbad Salt (Artificial) with Phenolphthalein, Mulford.—A mixture said to contain in each 100 Gm.: Potassium sulphate, 0.35 Gm.; sodium chloride, 3.266 Gm.; sodium bicarbonate, 6.533 Gm.; sodium sulphate (dried), 8 Gm., and phenolphthalein, 1.1 Gm., with an effervescent base consisting of sodium bicarbonate, and citric and tartaric acids. Each heaping teaspoonful of the salt will average about 90 grains and is said to contain about ⅓ grain of potassium sulphate, 3 grains of sodium chloride, 6 grains of sodium bicarbonate, 7 grains of sodium sulphate (dried) and about 1 grain of phenolphthalein.

Guaiacol Carbonate Comp.—Soft, elastic, soluble capsules, each of which is said to contain: Guaiacol carbonate, 0.09 Gm. (1½ grains); calcium hypophosphite, 0.03 Gm. (½ grain); ichthyol, 0.03 Gm. (½ grain), strontium arsenite, 0.00055 Gm. (1/120 grain), and olive oil sufficient to make 0.3 Cc. (5 minims). Trademark not registered.

National Pharmacy Co., Oakland, Cal.

Bismuthal.—A milky liquid, said to contain in 100 Cc. lac bismuthi citratis, 44 Cc.; pepsin, 3.30 Gm.; hydrochloric acid, 0.013 Gm.; lactic acid, 0.013 Gm.; glycerin, 40 Gm., and alcohol, 5 Cc.; cherry laurel water, 1.66 Cc.; Jamaica ginger, 0.26 Gm.; gum benzoin, 0.59 Gm. Each dose of 1 fluidram is said to contain approximately: Lac bismuthi citratis, 26 minims; pepsin, 2 grains; hydrochloric acid, 8/1000 grain; lactic acid, 8/1000 grain; glycerin, 24 grains; alcohol, 3 minims; cherry laurel water, 1 minim; Jamaica ginger, 1/6 grain; gum benzoin, ⅓ grain.

Lac bismuthi citratis contains 7.60 per cent. of anhydrous bismuth citrate. It is made by double decomposition between bismuth trinitrate and sodium citrate, decanting the supernatant liquid and washing the precipitate.

Pitman-Myers Co., Indianapolis, Ind.

Aromatic Cordial, P.-M. Co.—Aromatic cordial is a mixture said to contain in each 100 Cc.: Papain, 0.4 Gm., and lactic acid, 0.625 Cc. in a menstruum consisting of glycerin wine, aromatics, sugar, and 5 per cent. of alcohol. One fluidram is said to contain papain, ¼ grain, and lactic acid, 4/10 minim.

Elixir Buchu, Juniper and Acetate Potassium, P.-M. Co.—Each 100 Cc. is said to represent: Buchu, 16.6 Gm.; juniper berries, uva ursi, of each, 8.3 Gm.; potassium acetate, 5 Gm. Each fluidram is said to represent: Buchu, 10 grains; juniper berries, uva ursi, of each, 5 grains, and potassium acetate, 3 grains.

Oleum Ricini Dulce, P.-M. Co.—Castor oil to which has been added saccharin 0.07 Gm. in 100 Cc. (0.33 in a fluidounce) and aromatics; contains 2.5 per cent. alcohol.

Syrup Cannabis Compound.—Each 100 Cc. is said to represent: Cannabis indica, 1.66 Gm. (7½ grains in a fluidounce); heroin hydrochloride, 0.066 Gm. (⅓ grain in a fluidounce); chloroform, 0.83 Cc. (4 minims in a fluidounce); lobelia, 1.66 Gm. (7½ grains in a fluidounce); antimony and potassium tartrate (tartar emetic), 0.026 Gm. (⅛ grain in a fluidounce), with aromatics; alcohol, 10 per cent.

Tablets Acet-Phenetidin Compound, P.-M. Co.—Tablets, each stated to contain acet-phenetidin 0.23 Gm. (3½ grains); caffein, 0.016 Gm. (¼ grain) and sodium bicarbonate, 0.08 Gm. (1¼ grains).

Reinschild Chemical Co., New York.

Extractum Chinae Nanning.—A liquid extract of red chinchona said to contain cinchona alkaloids 5 per cent., cinchona tannins 7½-10 per cent., glycerine 30 per cent., water 55-57½ per cent.

Dosage.—1 to 1.25 Gm. (15 to 20 minims) three times a day.

_Regulin._*—A mixture of agar-agar in a dry form with extract of cascara sagrada representing 15 per cent. of an aqueous fluid extract of cascara sagrada.

Actions and Uses.—See Agar-agar. Regulin is used for the the treatment of habitual constipation.

Dosage.—From a teaspoonful to a tablespoonful once daily in stewed apples, mashed potatoes or similar food.

U. S. patent No. 896,807 (Aug. 25, 1908; expires 1925).

Russell & Lawrie, Tarrytown, New York.

_Lubraseptic._*—Lubraseptic is a jelly prepared from Chondrus (Irish moss) containing 2 per cent. boric acid and 0.067 per cent. formaldehyde.

The material is packed in screw cap metal tubes and sterilized by heat.

Dosage.—It is put up in collapsible tubes and it is suggested to reject the portion first expressed to make sure of the sterile condition of that used.

Schering & Glatz, New York.

_Tonols._*—Tonol is a name applied by E. Schering to identify the glycerophosphates of his manufacture. The following are mentioned: Calcium (or lime) tonol, Iron tonol, Lithium tonol, Magnesium tonol, Manganese tonol, Potassium tonol, Quinine tonol, Strychnine tonol. U. S. trademark No. 59,094.

_Duotonol._*—A mixture of equal parts of calcium tonol and sodium tonol. U. S. trademark.

_Quartonol._*—A name applied to a mixture of tonols in tablets of 0.3 Gm. (5 grains), each tablet being said to contain: Lime tonol. 0.148 Gm. (2¼ grains), sodium tonol, 0.148 Gm. (2¼ grains); quinine tonol, 0.03 Gm. (½ grain), and strychnin tonol, 0.00032 Gm. (1/200 grain). U. S. trademark.

_Sextonol._*—A mixture of tonols in tablets of 0.3 Gm. (5 grains), each tablet being said to contain: Lime tonol, 0.13 Gm. (2 grains); sodium tonol, 0.13 Gm. (2 grains); iron tonol, 0.03 Gm. (½ grain); manganese tonol, 0.015 Gm. (¼ grain); quinine tonol, 0.015 Gm. (¼ grain), and strychnine tonol, 0.00032 Gm. (1/200 grain). U. S. trademark.

Trikresol.—A liquid said to consist of: Orthocresol, 35 per cent.; metacresol, 40 per cent., and paracresol, 25 per cent. It closely corresponds to Cresol, U. S. P. U. S. trademark No. 65,624.

Schieffelin & Co., New York.

_Colalin Laxative._*—Tabella Colalinæ cum Extracto Rhamni Purshianæ, Crowell. Each tablet is said to contain colalin, 0.015 Gm. (¼ grain), powdered extract of cascara, 0.12 Gm. (2 grains), and podophyllin, 0.01 Gm. (1/6 grain).

Dosage.—One to three tablets on retiring or one after each meal.

_Elixir Eupncin._*—A preparation each 100 Cc. of which is said to contain: Heroin, 0.0325 Gm.; terpin hydrate, 1.625 Gm.; creosote, 3.75 Gm., in a menstruum containing 30 per cent. of alcohol, with glycerin and aromatic essential oils. Each dose of 2 fluidrams is said to contain: Heroin, 1/24 grain; terpin hydrate, 2 grains, and creosote, 5 grains. U. S. trademark No. 36,419.

_Hemoquinine._*—Each 100 Cc. is said to contain: So-called peptonate of iron (made by adding ammoniocitrate of iron to freshly prepared peptone of egg albumin), 7.2 Gm., and so-called peptonate of manganese, 1.8 Gm., together with: Quinine peptonate (equivalent to 0.5 Gm. of quinine sulphate). 1.0 Gm., and sodium arsenate, 0.266 Gm., in a menstruum containing 20 per cent. of alcohol with glycerin and aromatics. Each dose of 2 fluidrams is said to contain: Peptonate of iron, 8½ grains; peptonate of manganese, 2⅛ grains, peptonate of quinine, 1 grain, and sodium arsenate, 1/36 grain. U. S. trademark No. 38,512.

_Heromal._*—Each 100 Cc. is said to contain: Heroin, 0.01625 Gm. and sodium hypophosphite, 0.375 Gm., in a menstruum of malt extract, with 6 per cent. of alcohol. Each dose of 2 fluidrams is said to contain: Heroin, 1/48 grain, and sodium hypophosphite, ½ grain. U. S. trademark No. 37,010.

Heroterpine.—Each 100 Cc. is said to contain: Terpin hydrate, 1.625 Gm., and heroin, 0.0325 Gm., in a menstruum containing 32 per cent. of alcohol, with glycerin and aromatic essential oils. Each average dose of 2 fluidrams is said to contain: Terpin hydrate, 2 grains, and heroin, 1/24 grain. U. S. trademark No. 36,181.

Laminoids Ferruginous (Nascent).—Each tablet contains iron sulphate and sodium bicarbonate in quantities equivalent to those of pilulæ ferri carbonatis (Blaud's pills), but the two salts are separated into two layers so that the formation of ferrous carbonate will occur only when the tablets are moistened. An excess of bicarbonate is present. U. S. trademark No. 38,384.

_Neuronidia._*—An elixir said to contain in each 100 Cc.: Veronal (Diethyl-Barbituric Acid), 3.25 Gm. in a menstruum containing 35 per cent. of alcohol, with aromatics. Each dose of 2 fluidrams is said to contain veronal, 4 grains. U. S. trademark No. 44,141.

_Uriform._*—Each 100 Cc. is said to represent: Hexamethylenetetramine, 6.25 Gm.; saw palmetto, 4.16 Gm.; santal, 2.08 Gm.; damiana, 2.08 Gm., and nux vomica, 0.2 Gm., in a menstruum containing 20 per cent. of alcohol, with sugar and aromatics. Each dose of 2 fluidrams is said to contain: Hexamethylenetetramine, 7½ grains; saw palmetto, 5 grains; santal, 2½ grains; damiana, 2½ grains, and nux vomica, ¼ grain. U. S. trademark No. 37,924.

Leonard A. Seltzer, Detroit, Mich.

_Eusemine._*—A sterile solution, in hermetically sealed vials, of: Cocaine hydrochloride, 0.0075 Gm. (0.116 grains), and Adrenalin hydrochloride, 0.00005 Gm. (0.008 grains), dissolved in physiologic salt solution, 1 Cc.

Sharp & Dohme, Baltimore, Md.

Compressed Tablets Anesthesin, 2 1/2 grains.—Each tablet contains anesthesin, 0.162 Gm. (2½ grains).

Solution Atoxyl 10 per cent. (Sterilized).—Each 100 Cc. contain atoxyl, 10 Gm. (each fluidounce contains atoxyl, 48 grains), dissolved in distilled water.

Ampules Solution Atoxyl, 10 per cent. (Sterilized).—Each 100 Cc. contain atoxyl, 10 Gm. (each fluidounce contains 48 grains), dissolved in distilled water.

Ampules Solution Atoxyl, 10 per cent., with Novocaine, 1 per cent. (Sterilized).—Each 100 Cc. contain: Atoxyl, 10 Gm., and novocaine, 1 Gm. (each fluidounce contains: Atoxyl, 48 grains, and novocaine, 4 8/10 grains), dissolved in distilled water.

Compressed Tablets Atoxyl and Iron.—Each is said to contain: Atoxyl, 0.02 Gm. (⅓ grain), and ferrous lactate, 0.06 Gm. (1 grain).

Compressed Tablets Atoxyl and Quinine Comp.—Each tablet contains: Atoxyl, 0.01 Gm. (1/6 grain), quinine hydrochlor, 0.022 Gm. (⅓ grain), strych. nitrate, 0.0043 Gm. (1/150 grain), ferrous carbonate mass (Blaud), 0.162 Gm. (2½ grains).

Compressed Tablets Benzosol, 2 1/2 grains.—Each tablet contains benzosol 0.162 Gm. (2½ grains).

Compressed Tablets Benzosol and Codeine.—Each tablet contains: Codeine sulph., 0.0054 Gm. (1/12 grain), and benzosol, 0.162 Gm. (2½ grains).

Compressed Tablet Blaud with Atoxyl.—Each tablet contains Ferrous carb. mass (Blaud), 0.162 Gm. (2½ grains), and atoxyl 0.022 Gm. (⅓ grain).

Compressed Tablets Pyramidon, 1 1/2 grains.—Each tablet contains pyramidon, 0.097 Gm. (1½ grains).

Compressed Lozenges Orthoform, 1 grain.—Each lozenge contains orthoform, 0.065 Gm. (1 grain).

Compound Emulsion Petroleum, S. & D.—An emulsion containing: Refined petroleum, 28⅓ per cent.; petrolatum oil, 5 per cent., with calcium hypophosphite, 2.2 Gm., and sodium hypophosphite, 2.2 Gm. in each 100 Cc. Each dose of 4 fluidrams is said to contain: Calcium hypophosphite, 5 grains, and sodium hypophosphite, 5 grains.

---

* For significance of star see foot-note under Tabloid Coffee Mint, p. 70.

Liquor Santaira.—Liquor Santali et Copaibae Compositus, S. & D.—Each 100 Cc. contains Santal oil 1 Cc. (5 minims in a fluidounce) and copaiba 2 Cc. (10 minims in a fluidounce) dissolved in 55 per cent. alcohol with addition of aromatic oils.

Solution Atoxyl, 10 per cent., with Novocaine, 1 per cent. (Sterilized).—Each 100 Cc. contain: Atoxyl, 10 Gm., and novocaine, 1 Gm. (each fluidounce contains atoxyl, 48 grains, and novocaine, 4 8/10 grains), dissolved in distilled water.

Soluble Hypodermic Tablets Atoxyl, 1/3 grain.—Each tablet contains atoxyl, 0.02 Gm. (⅓ grain).

Soluble Hypodermic Tablets Novocaine, 1/3 grain.—Each tablet contains novocaine, 0.02 Gm. (⅓ grain).

Soluble Tablets Novocaine, 1 1/7 grains.—Each tablet contains novocaine, 0.074 Gm. (1 1/7 grains).

*Tonic Hypophosphites.**—Each 100 Cc. is said to contain: Potassium hypophosphite, 0.33 Gm. (1½ grains in a fluidounce); iron hypophosphite, 0.33 Gm. 1½ grains in a fluidounce); manganese hypophosphite, 0.22 Gm. (1 grain in a fluidounce); calcium hypophosphite, 0.22 Gm. (1 grain in a fluidounce); quinine hypophosphite, 0.10 Gm. (½ grain in a fluidounce); strychnine hypophosphite, 0.013 Gm. (1/16 grain in a fluidounce.

F. H. Strong Co., New York.

*Chologestin.**—A liquid of which 100 Cc. is said to contain the amorphous sodium salt of glycoholic acid, 0.858 Gm.; true sodium salicylate from the natural oil of wintergreen, 1.07 Gm.; pancreatin, 2.15 Gm.; sodium bicarbonate, 2.15 Gm., in a menstruum containing 15 per cent. alcohol. Each half ounce is said to contain the amorphous sodium salt of glycoholic acid, 2 grains; true sodium salicylate from the natural oil of wintergreen, 2½ grains; pancreatin, 5 grains; sodium bicarbonate, 5 grains. U. S. trademark No. 61,767.

Veroform Hygienic Co., New York.

Veroform Germicide.—A practically neutral liquid containing 20 per cent. of formaldehyde gas dissolved in a solution of soap.

Veroform Antiseptic.—A practically neutral liquid containing 6 per cent. of formaldehyde gas dissolved in a solution of soap. U. S. patent No. 740,424 (Oct. 6, 1903; expires 1920). U. S. trademark "Veroform" No. 44,144.

H. K. Wampole Co., Philadelphia.

Bismuth Hydrate Comp.—A mixture containing in each 100 Cc.: Alcohol, 2 per cent.; chloroform, 0.4 Cc. (2 minims in a fluidounce); fluidextract of red gum (eucalypti gummi), 6.6 Cc. (32 minims in a fluidounce); phenyl salicylate, 0.20 Gm. (1 grain in a fluidounce); pepsin, 0.8 Gm. (4 grains in a fluidounce); bismuth hydroxycarbonate, an amount corresponding to 1.2 Gm. (6 grains in a fluidounce); antiseptic oils and aromatics, and glycerin, 20 per cent. No patents or trademarks.

Colchi-Methyl Capsules.—Each capsule contains: Colchicine, 0.00025 Gm. (1/250 grain); phenyl salicylate (salol), 0.13 Gm.

Glycerodine.—Glyceritum acidi hydriodici. It is said to contain in each 100 Cc. hydrogen iodide (absolute hydriodic acid), 1.54 Gm. (7 grains in a fluidounce).

OBSTETRICS AND ANIMAL EXPERIMENTATION [*]

J. WHITRIDGE WILLIAMS, M.D.
Professor of Obstetrics, Johns Hopkins University
BALTIMORE

Unfortunately, the relation between animal experimentation and obstetrics appears at first sight to be less direct and striking than in many other branches of medicine. Nevertheless, I consider that it can be demonstrated beyond peradventure that the greater part of the advances made during the past thirty-five years have resulted either directly or indirectly from research of this character.

The chief advances in obstetrics, in which animal experimentation has played a part, may be summarized as follows:

1. The recognition of the bacterial origin of puerperal infection, which has enabled us to prevent and overcome its former terrible mortality.
2. The application of aseptic technic to various obstetrical operations, thereby rendering comparatively harmless many procedures which were formerly murderous.
3. The recognition of the bacterial nature of certain infectious diseases of the newly born child, such as lockjaw and umbilical infections, which enables us to save each year the lives of thousands of infants, which under former conditions would have been lost.
4. The biologic study and standardization of certain drugs, such as ergot, whereby efficient preparations are available for the prevention and control of hemorrhage.
5. The demonstration of the internal secretion of the ovary, which has led to the therapeutic employment of ovarian tissue extracts, and to greatly increased conservatism in operations on the ovaries.
6. Experimental studies concerning the nature of the toxemias of pregnancy.
7. The experimental production of fetal deformities, which has led to a clearer conception of teratology, and the abandonment of the superstitious belief in maternal impressions.

1. *THE RECOGNITION OF THE BACTERIAL ORIGIN OF PUERPERAL FEVER*

Those not familiar with the older obstetrical literature scarcely realize the extent of the ravages of puerperal infection before the introduction of rigid antiseptic precautions in the conduct of labor, as well as the almost miraculous revolution which has followed their employment.

In this connection, I shall attempt to give some idea of the mortality attending puerperal infection in the past, and of the confusion regarding its nature. Then I shall refer to the part played by animal experimentation in the development of the bacteriology of wound infection and the establishment of aseptic technic, as well as the demonstration of the bacterial nature of puerperal infection, and finally I shall refer briefly to the revolutionary results which have followed the practical application of these principles.

In preantiseptic times puerperal fever ravaged the lying-in hospitals throughout the world, and each year caused the unnecessary death of thousands of women in the best years of life. How great the mortality was can best be appreciated by referring to the results obtained in the various civilized countries of the world, prior to the recognition of the etiologic rôle of the streptococcus.

PUERPERAL FEVER IN FRANCE

LeFort, in his railing accusation against the lying-in hospitals of France, which appeared in 1866, calculated that 30,394 deaths from puerperal fever had occurred in the 888,312 women delivered in the hospitals of Paris up to the year 1864—an incidence of 3.5 per cent., or one death to every 27.2 labors. Moreover, he stated that from 1860 to 1864, inclusive, the mortality in the Maternité of Paris was 12.4 per cent., which in December, 1864, rose to the colossal height of 57 per cent.; while in the Clinique it averaged 14.7 per cent. between the years 1833 and 1864, and on several occasions rose above 20 per cent. On the other hand, the mortality outside of the hospitals was much less, as only one woman perished out of every 212, which indicated that seven-eighths of the hospital deaths were due to conditions prevailing in them.

Such results were not limited to the past century, as Tenon in 1788 reported that the mortality at the Hôtel-Dieu for the fifteen years prior to 1786 was 6.4 per cent., and described almost inconceivable conditions of overcrowding and filth. Other observers described similar conditions. Thus, Charrier recorded a mortality of 7.5 per cent. at the Maternité in 1854, and Depaul one of 5.3 per cent. at the Clinique in 1856. Tarnier in his graduation thesis pointed out that 114 deaths from puerperal fever had occurred at the Maternité during the year 1856, an incidence of 5.1 per cent., as compared with 0.31 per cent. in the portion of the city immediately adjoining it.

Malgaine likewise studied the results in 14,197 and 99,911 women delivered respectively, in the hospitals and in the city of Paris during the years 1861 and 1862, and found a mortality of 8.2 and 0.56 per cent.; while

---

[*] This paper is one of the series prepared for and reprinted by the Bureau on Defense of Medical Research of the Council on Health and Public Instruction of the American Medical Association for circulation among the public. Twenty of these pamphlets are now ready, taking up the relations of animal experimentation to ethics, diagnosis, cancer, vaccination, the live stock industry, tuberculosis, typhoid, dysentery, plague, rabies, surgery, internal secretions, circulation of the blood, tropical diseases, syphilis, obstetrics, etc. A price-list will be sent on application. This article is abbreviated in THE JOURNAL. The pamphlet contains the complete article, including a long bibliography.

Quinquaud stated that 65 per cent. of all women delivered in the St. Antoine Hospital during the year 1869 were infected. Moreover, Delaunay in his recent history of the Maternité de Paris reports that the average mortality for the ten years ending with 1869 was 10.12 per cent., which rose as high as 18.43 per cent. in 1864.

Naturally, such results could not pass unnoticed, and the subject was frequently brought up for discussion. Thus, following a paper on puerperal fever by Guérard before the Académie de Médecine in 1858, a discussion arose which lasted for five months, which led to no definite conclusions, although participated in by the leading authorities in France. Similar discussions also occurred before the Académie in 1861 and 1862, the Société de Chirurgie in 1866, and the Société médicale des hôpitaux in 1869 and 1870. In all of them the most divergent views were expressed, some speakers holding that puerperal fever was contagious, and others that it was an unavoidable visitation of Providence. All sorts of theories were advanced in explanation of its origin, and it was attributed in turn to the peculiar characteristics of the parturient and puerperal woman, to hospital miasms and to the filthiness, faulty construction and ventilation of the hospitals; but not a word was said concerning the dirty hands of the obstetrician. Every suggestion was tested as soon as made, but still the mortality continued unchecked. Finally, in desperation it was suggested that the old lying-in hospitals be abandoned and be replaced by smaller ones, accommodating only a limited number of women, and that most women be cared for in their own homes or in small institutions conducted by specially appointed midwives. At the end of this period, the results had become so intolerable that it became the prevailing opinion that epidemics could be combated only by closing the lying-in hospitals, and such a drastic remedy was forcefully recommended at the International Congress held at Brussels in 1875.

The prevalence of puerperal fever had become a scandal, and, passing beyond purely medical circles, engaged the earnest attention of the Bureau of Public Assistance, whose able director, Husson, after thoroughly investigating the subject, was forced to admit that he saw no way of coping with it, and said:

> For the past sixty years the combined efforts of the administration and of the chiefs of service of health, have not been able to control the curse of puerperal fever, and up to this time the only palliative means of any effect in opposing the evil has been the momentary evacuation of the infected wards. The figures received from the various services of obstetrics still show a mortality high enough to call forth investigation, and to engage the friends of science and humanity to search in every possible way by what means it may be possible to arrest the progress of so terrible a malady, which up to the present time has disappointed all calculations.

It is interesting to note that the monumental work of LeFort, whose statistics are quoted above, was undertaken at the instigation of Husson; but, when the report was ready and showed so clearly the glaring conditions in France, the Bureau of Public Assistance would not allow it to be published under its auspices. The following quotation from Hervieux's immense work on puerperal infection, which appeared in 1870, will also serve to indicate the gravity of the situation:

> The puerperal epidemics are to woman what war is to man. Like war they destroy the most healthy, the bravest and the most useful portion of the population; like war they take subjects in the flower of their age and spread terror and desolation throughout the territory which they devastate. It belongs to politics to preserve us from the calamities of war, but to medicine is reserved the task of preventing and doing away with such epidemics.

PUERPERAL FEVER IN GERMANY

Conditions similar to those in France likewise obtained in Germany, but owing to the smaller size of its lying-in hospitals, the epidemics were usually not so extensive.

On behalf of the Berlin Obstetrical Society, Boehr in 1877 undertook to study the mortality from puerperal fever in Prussia, and found that in the sixty years ending with 1875 the appalling number of 363,624 women had died from it in that state alone. Moreover, he calculated that the disease was the cause of 12 per cent. of the total number of deaths occurring in both sexes between the ages 15 and 50 years which increased to 18.58 per cent. between the ages 25 and 30 years. Furthermore, assuming that each marriage would result in 4.2 children, he estimated that every thirtieth married woman in Prussia would eventually fall a victim to it.

Based on Boehr's work, and its own investigations, a committee of the society presented a *Denkschrift* to the minister of education, in which it was stated that many more persons died from puerperal fever than from cholera and small-pox combined, although sixteen epidemics of the former disease had occurred during the period covered by the statistics. For the protection of the public health, it was urged that the disease be made a "notifiable" one, so that steps could be taken to regulate the practice of midwives. Hegar made a similar study of the conditions in Baden and found that 0.732 per cent. of all labors ended fatally, one-half of the total number of deaths being due to puerperal fever.

The work of Boehr was continued by Ehlers in 1900, who found as the result of aseptic precautions that the mortality in the large cities had been reduced by one-half, but had remained practically unchanged in the country districts.

PUERPERAL FEVER IN GREAT BRITAIN

Epidemics of puerperal fever were reported in the eighteenth century by Hunter, Denman, Hulme, Leake, Kirkland, Clarke, White, Gordon and others, the most extensive being that recorded by White in the Lying-In Hospital of Manchester, where the mortality was 4.1 per cent. between the years 1755 and 1771. Owing to the comparatively small size of the lying-in hospitals of Great Britain, and particularly to the early recognition by English physicians of the contagious nature of puerperal fever and its relation to erysipelas, the epidemics were not so extensive and were less fatal than those on the continent; nevertheless, prior to the antiseptic period the results obtained were very discouraging. Until recently, the Rotunda Hospital in Dublin was the only large lying-in institution in the British Empire, and its results have been recorded by Churchill, Kennedy and Steele. The latter stated that in 198,481 labors, occurring up to the year 1870 the average mortality was 1.32 per cent., which rose to 3.27 per cent. between 1861 and 1870. He also reported that for the twenty-two years preceding and including 1876, the several London lying-in hospitals presented the following mortalities:

	Per cent.
Queen Charlotte Hospital	2.82
British Lying-In Hospital	1.57
General Lying-In Hospital	1.41
City of London Lying-In Hospital	1.35

Some idea of the seriousness with which the condition was regarded was shown by the appearance of an editorial in the *Lancet*, only a few weeks after the appearance of Lister's first article on antiseptic surgery, recommending the closing of all lying-in hospitals. Moreover, Kennedy in 1869 advocated evacuating the Rotunda Hospital in Dublin and delivering the women in tents or shacks scattered throughout its grounds; while Florence Nightingale considered that large lying-in hospitals could never be conducted safely and that their employment for the training of students was incompatible with a low death-rate.

Following a paper by Spencer Wells, the entire question of puerperal infection was thoroughly discussed before the London Obstetrical Society in 1875. All of the prominent obstetricians of the time took part in the discussion, and, while the most divergent views were expressed concerning its nature, the general consensus of opinion, well illustrated by the following quotation, was that lying-in hospitals had an inherent mortality which could probably never be overcome:

> There is only one secret of safety, and that is to have the woman confined at her own house where she can have her own nurse, who has not been anywhere in the way of infection, and her own medical man who is free from infection. Then the chances are that she will come on favorably and happy. Without that there is no security. The lying-in hospital is not now by any means so serious a matter as it used to be: still it is always like sitting on a volcano; it may explode at any moment (Barnes).

Furthermore, the general feeling of hoplessness was well expressed by Duncan, in his monograph on "The Mortality of Childbed," when he said:

> The disease may have its ravages restricted, but it is yet to be shown that it can be altogether prevented. It is in truth as little preventable as any disease in the nosology, or any crime in the statute-book. It is possibly preventable, but it has certainly never been prevented.

Even after the introduction of antiseptic methods, the views as to the undesirability of lying-in hospitals continued to persist in England; and as late as 1885 one of the sections in Playfair's text-book on midwifery was entitled "Should Lying-In Hospitals Be Abolished?" Indeed, the improvement in that country has been less marked than elsewhere: Cullingworth, after studying the statistics of the Registrar General's office for 1897, stated that the general mortality had shown no decrease, except as compared with the year 1843; Boxall reported a similar condition of affairs as late as 1905.

PUERPERAL FEVER IN THE UNITED STATES

That the United States was not spared in this regard is shown by the fact that Hodge reported a mortality of 5.6 per cent. in the Pennsylvania Hospital for the thirty years preceeding 1833. Lusk observed an epidemic in the Bellevue Hospital in 1872 with a mortality of 18 per cent., which led to the removal of the department to Blackwell's Island. But even there the infection continued until after the introduction of antiseptic methods. Similar results were observed in the New York Maternity Hospital, where Garrigues noted a mortality of 4.17 per cent. for the years 1875–1883, which in the latter year, just prior to the introduction of antiseptic methods, rose to 7.17 per cent.

VIEWS CONCERNING THE NATURE OF PUERPERAL FEVER

Sedillot stated in 1817 that puerperal fever was not a distinct disease, but rather an ordinary infection, which was modified by the puerperal state. It required, however, nearly seventy years before this doctrine became generally accepted.

The infectious nature of puerperal fever was first clearly emphasized by Gordon of Aberdeen, who based his conviction on seventy-seven cases observed during an epidemic in Aberdeen between the years 1789 and 1792. Among other things, in his forceful monograph, he wrote:

"It is a disagreeable declaration for me to mention that I myself was the means of carrying the infection to a great number of women"; and, in another place, "Fresh air and cleanliness are not sufficient for the destruction of the contagion, which can only be effected by fire and smoke."

Notwithstanding these clear-cut teachings, and the conclusive evidence which Gordon adduced in their support, the medical world was but little affected, and it was not until after the introduction of Listerian methods that such ideas became generally accepted. Similar views were forcibly and eloquently expressed in 1843 by Oliver Wendell Holmes in his monograph on "The Contagiousness of Puerperal Fever," which was reprinted with additions in 1855 under the title "Puerperal Fever as a Private Pestilence." His teachings, however, were opposed by Hodge and Meigs, the leading obstetricians of the day, and, while impressing many practitioners with the necessity of temporarily abstaining from obstetric work when several fever cases had occurred in their practice, they had no effect on the results obtained in lying-in hospitals. Kneeland expressed similar views in 1847, which met with the same fate.

The most important contribution to this aspect of the subject was made by Semmelweis in 1847, who, after carefully studying the causes underlying the horrible mortality in the lying-in hospital of Vienna, came to the conclusion that the disease was identical with wound infection, and was due to the contamination of patients by hands soiled by contact with autopsy material or wound secretions. Furthermore, he thought that its propagation could be checked by washing the hands in a solution of chlorinated lime, by which means he was able to reduce the mortality from 11.4 to 1.27 per cent.

Semmelweis' views concerning the nature and causation of puerperal fever were perfectly clear; and if, in the following quotation, one substitutes the words "pyogenic bacteria" for "decomposed animal organic material" his conception holds perfectly good at the present time. After stating that he regarded child-bed fever as a resorption fever, he continued:

> The decomposed animal organic material, which when absorbed causes child-bed fever, is in the vast majority of cases brought to the individual from without. These are the cases which represent child-bed fever epidemics, and these are the cases which can be prevented. The carrier of the decomposed animal organic material is the examining finger, the operating hand, bed-clothes, the atmospheric air, sponges, the hands of midwives and nurses which have been in contact with the excreta of seriously sick puerperal women or other ill persons and then handle parturient or recently delivered women. In a word, the carrier of the decomposed animal organic material is anything which has been contaminated by decomposed animal organic material and then comes in contact with the genitals of the individual. The area from which the decomposed animal organic material is absorbed is the internal surface of the uterus, extending upward from the internal os. As the result of pregnancy this has been robbed of its mucous membrane, and accordingly presents a surface which is unusually adapted for absorption.

In spite of these clear-cut views, his teachings were opposed by the leading authorities of Germany and France, and he died a disappointed man. He nevertheless prophesied that his views would eventually be universally accepted, and, in a postscript to his great work, wrote:

> But should it not be vouchsafed me, which I hope God may prevent, to see this happy time with my own eyes, nevertheless the conviction that such a time must inevitably come sooner or later will cheer me in my dying hour.

Almost simultaneously with Semmelweis, Simpson insisted on the contagious nature of the disease and its identity with ordinary wound infection. More or less similar views were also expressed by Tarnier in 1856 and by Trousseau in 1858; but it was necessary for many years to elapse before they were accepted by the general mass of the profession.

A similar divergence of opinion continued until after 1875, when the discoveries of Lister and the bacterial origin of puerperal fever first began to be accepted. Prior to that time, the condition was generally considered as unavoidable, and was attributed to cosmic, atmospheric or telluric influences, to the genius epidemicus, imperfect ventilation and all sorts of other conditions; but, with the exception of a few far-seeing men, no one believed that it could be communicated from one patient to another by means of a dirty finger.

The teachings of Lister were introduced into France in 1875 by Championnière and Budin, and were popularized in Germany by a personal tour. Ahlfeld has given an interesting reminiscence of Lister's visit to Leipsic at that time, and has preserved a verse sung in his honor.

Just sind es jetzt fünf Jahre her,
Da drang die Kunde übers Meer;
Es lebt ein Mann in Edinburg,
Das sei ein eigener Chirurg,
In Karbolnebel eingehüllt,
Der rings die Luft mit Dünsten füllt,
Betriebe er mit aller Macht,
Die niedere Bakterienjagd . . .

Prior to that time only a few voices were raised in support of the bacterial nature of puerperal fever, and Lee and Sir Spencer Wells were practically alone in England in advocating it. Indeed, such views did not begin to receive general acceptance until after Pasteur had cultivated the streptococcus and demonstrated it before the Académie de Médecine de Paris, in March, 1879.

It is interesting to recall the fact that this demonstration was preceded by a paper by Hervieux, in which he said:

> "I lay down the principle that the inferior organisms as yet known, vibrions, bacteria, batonnets and moving bodies, cannot possibly explain the production of puerperal septicemia," and concluded, "but I must confess that I have a terrible fear, a fear from which I am not able to rid myself, and which the academy will understand; and that is that I shall die before any one will have discovered that vibrion."

Immediately afterwards Pasteur arose and drew on the blackboard several chains of little dots, which he stated he had every reason to believe were its actual cause. This was the beginning, but many years of persistent investigation were required before the bacterial nature of puerperal infection was universally recognized.

THE DEVELOPMENT OF BACTERIOLOGY; AND RECOGNITION OF BACTERIAL ORIGIN OF PUERPERAL INFECTION

This is not the place to trace the history of the development of bacteriology in general, or even its application to wound infection. As far as I can learn, the relation of bacteria to infectious diseases, and the necessity of recourse to animal experimentation for its demonstration, was first clearly expressed by Henle in 1840. He prophesied that the "contagium" in infectious diseases must be a living organism, and laid down the following criteria, which must be fulfilled in order to prove such a relationship:

1. The constant presence of one and the same microorganism.
2. Its isolation.
3. The experimental study of the same by animal experimentation.

Following this, the development of bacteriology as applied to medicine was comparatively slow, and it was not until after the work of Pasteur on putrefaction, and the application of his ideas to surgery by Lister, that very considerable advances were made. Indeed, it may be said that extensive development along these lines was not possible until after Koch, by the discovery of solid culture media, had put into our hands a convenient method of isolating and cultivating bacteria. Almost immediately following this invention, the various bacteria concerned in ordinary wound infection were isolated and their pathogenic action demonstrated experimentally on animals. Aside from Pasteur and Koch, the greater part of this work was done by Ogston, Rosenbach, Passet, Garre and Fehleisen, and so convincing was their demonstration, that the information concerning the pyogenic cocci given in Baumgarten's "Handbuch der pathologischen Mycologie" in 1887 is almost as satisfactory as that available at the present time. Moreover, between the years 1884 and 1889, the work of Carle and Rattone, Nicolaier and Kitasato resulted in the isolation of the tetanus bacillus, and the conclusive experimental demonstration of its pathogenic action.

All of these discoveries were based on animal experimentation, and indeed it may be said that none of the important advances in bacteriology would have been possible without its aid. Occasionally, enthusiastic investigators, such as Bumm, Garre, Bockhart and Fehleisen, made experiments on their own persons, and thereby still further convinced themselves of the pathogenic properties of certain pyogenic bacteria.

Following the recognition of the bacteria concerned in the production of wound infection, it became possible to test the efficiency of the various antiseptics recommended for their destruction. It is particularly to Koch that we are indebted for the fundamental contribution to the doctrine of disinfection, and for the demonstration of the great value of bichlorid of mercury. Further investigation, however, gradually materially impaired our faith in the efficacy of antiseptics, and led to the development of aseptic surgery.

As far as I have been able to learn, Semmelweis in 1846 was the first to resort to animal experimentation in the hope of solving the problem of puerperal infection. He introduced into the freshly delivered uterus of animals, uterine discharges and peritoneal exudate from infected women, and in the majority of instances was able to produce a fatal infection. Animal experiments were also made by Tarnier, Mayrhofer, Coze and Feltz, Quinquad, Orth, Heiberg, Eberth, D'Espine, Kehrer, Karewsky, Miller, Pasteur and Doléris and many other later investigators.

Of these Mayrhofer, Coze and Feltz, Pasteur and Doléris deserve especial mention. The former in 1864 observed in the interior of the infected uterus, bacteria, which he described as vibrions, and by the injection into animals of lochia containing them was able to reproduce the disease. Coze and Feltz in 1869 apparently demonstrated the presence of streptococci in the blood of women dying from puerperal fever, and cultivated them in rudimentary fluid culture media. They also produced death in animals by their innoculation. As has already been mentioned, Pasteur was the first to describe clearly, and to cultivate the streptococcus from cases of puerperal infection, and together with his collaborator Doléris effectively demonstrated its etiologic significance.

Following Pasteur, it has gradually been demonstrated that, while the streptococcus is the organism most usually concerned in the production of fatal puerperal infections, all of the pyogenic bacteria, which play a part in ordinary wound infection, may likewise give rise to them. Scarcely any one who has busied himself with their study has failed to resort to animal experimentation, and none of the recent advances along this line would have been possible without its aid.

Listerian methods were not adopted in gynecology and obstetrics until after 1875, and for the succeeding few years the chief reliance was placed on the free use of phenol for disinfecting the hands and dressings and for use as a spray. Such precautions were soon carried to ridiculous extremes, and at the acme of the antiseptic period it was thought necessary to remove all furniture from the room in which a woman was to be confined, to scrub the walls and floors with a phenol solution and to have a nebulizer spray it on the external genitalia during the second stage of labor. At the same time, disinfection of the hands was slighted, as it was believed that their immersion in a phenol solution for a few moments was sufficient to render them absolutely sterile. As these precautions did not lead to the complete disappearance of puerperal infection, the attempt was made to destroy all bacteria in the birth canal by means of vaginal and intra-uterine douches of phenol solution, or of bichlorid of mercury, after its introduction in 1881.

With the gradual development of clearer ideas concerning the process of infection and the limitations of disinfection in general, the employment of antiseptic methods was gradually abandoned and its place taken by the aseptic technic which we now employ, in which less and less importance is attached to chemical disinfection and increasingly more weight laid on absolute subjective and objective cleanliness.

RESULTS FOLLOWING THE EMPLOYMENT OF ANTISEPTIC AND ASEPTIC TECHNIC

Following the introduction of antiseptic methods into obstetrics, there occurred a marked diminution in the death-rate from puerperal infection, which however, was nothing like so great as in the later or aseptic period. Thus, Dohrn analyzed the results obtained in 104,278 women delivered in forty-seven German lying-in institutions between the years 1874 and 1883 inclusive, and found an average mortality of 1.37 per cent. At the beginning of the period it was 1.73 per cent., and became reduced to 0.96 per cent. at its end. Moreover, it is interesting to note that the worst results were obtained in the institutions used for the instruction of students, while the best were in those not employed for teaching purposes, the mortality averaging 1.9 and 0.56 per cent., respectively.

When compared with the mortality of 3 or 4 per cent., which characterized the previous decade, the results were most encouraging; and Dohrn felt that they probably could not be improved on, as he stated that "the mortality in lying-in hospitals will never be lowered for any great length of time to the percentage prevailing in private practice; and, if we estimate the latter at 0.6 to 0.7 per cent., the institutional mortality would still be nearly double as high. The lying-in institutions have to contend with such unfavorable conditions that such results as in private practice would never be permanently possible."

Bar stated that, following the introduction of antiseptic methods in the Maternité of Paris, the mortality fell to 1 per cent. in 1873 and to 0.8 per cent. in 1882; while Tarnier has given a very graphic picture of the conditions in the same hospital. For this purpose he distinguished three periods; namely, from 1858 to 1869, from 1870 to 1880, and from 1881 to 1889, and designating the first as the period of inaction, the second as that of fight against contagion and the third as the antiseptic period, recorded a mortality of 9.31, 2.32 and 1.05 per cent., respectively. On the other hand, as many patients died as previously at the Clinique, where Depaul and Pajot, who did not believe in the bacterial nature of the disease, continued to use the old methods.

With the gradual development of aseptic technic and more rigid precautions for the prevention of infection, better and better results were obtained, so that Mermann in 1907 was able to report a septic mortality of only 0.08 per cent. in 8,700 patients delivered under his supervision in Mannheim. Pinard in 1909 recorded a net mortality of 0.15 per cent. in 45,633 deliveries in the Baudelocque Clinic during the eighteen years ending with 1908; while in the same year Markoe recorded a percentage of 0.34 in 60,000 women delivered by the Society of the New York Lying-in Hospital.

At the present time it is safe to say that in well-regulated hospitals the mortality from puerperal infection is less than 0.25 per cent. This is in great contrast with the average mortality of 3 to 4 per cent. observed throughout the world prior to the introduction of antiseptic methods, and means that only one woman now dies as compared with fifteen or twenty formerly. Moreover, the criterion of excellence in lying-in hospitals is now not so much the actual mortality as the morbidity of patients; namely, the percentage in whom the temperature rises to 38 C. or 100.4 F. during the first ten days of the puerperium.

This improvement is astounding, and at the present time it is safe to say that fewer deaths from infection occur in well-regulated lying-in institutions than in private practice, notwithstanding the fact that in the former the patients are freely used for clinical instruction. In this regard Dohrn and Florence Nightingale were poor prophets, as the former stated that such results would never be attained; while the latter held that hospitals could not be rid of puerperal infection as long as they were used for the instruction of students.

This revolution must be attributed to animal experimentation, which made possible the demonstration that definite bacteria are the cause of wound infection, and that one of its varieties—puerperal infection—is due to the introduction of pyogenic bacteria into the birth canal of parturient women, and can be prevented by appropriate means. Of course, it may be urged that far-seeing men, such as Gordon, Holmes, Semmelweis and Tarnier realized the contagious nature of puerperal fever long before bacteriology became a science. They were not, however, able to impress their belief on the profession, and consequently no improvement was observed until the bacterial nature of the disease was clearly demonstrated. Formerly, the obstetrician groped in the dark in his attempt to identify the unknown contagion, if he even believed in its existence; while now we know exactly with what microorganisms we have to deal, and the means to adopt in order to overcome them.

At the present time, puerperal infection is no longer regarded as a visitation of Providence, but is attributed directly to the introduction of bacteria following a "break" in aseptic technic; and, whenever a case occurs in a well-regulated hospital, the director immediately begins to inquire how it happened, and, having found the source, is at once able to put a stop to further spread of the disease.

2. *THE APPLICATION OF ASEPTIC TECHNIC TO OBSTETRIC OPERATIONS*

The same factors which led to the disappearance of puerperal fever from lying-in hospitals and made possible the wonderful advances in general surgery, played an identical part in revolutionizing the results following the various operative procedures in obstetrics.

This is most strikingly illustrated by contrasting the results following Cesarean section and symphyseotomy or pubiotomy during the preantiseptic period and at the present time. Even as late as 1886, Dr. Robert Barnes wrote:

> The Cesarean section occupies a doubtful place between conservative and sacrificial midwifery. It is conservative in its design, in its ambition; it is too often sacrificial in fact. It is resorted to with a feeling akin to despair for the fate of the mother, which is scarcely tempered by the hope of rescuing the child. It is looked upon by the great majority of obstetricians as a last desperate resource, as the most forcible example of that kind of surgery which John Hunter regarded as the reproach of surgeons, being a confession that their art was baffled.

From 1787 until 1879, when Tarnier reported his first operation under antiseptic precautions, not a single successful Cesarean section had been performed in Paris; while Lusk, in the early eighties, was the first successful operator in New York. Indeed, as late as 1887, Harris stated that Cesarean section could be performed more safely by the horn of an infuriated bull than by the most accomplished surgeon in the best-equipped hospital in America. In support of this statement, he collected from the literature nine instances in which the abdomen of pregnant women had been ripped open by the horn of an infuriated bull, with five recoveries; whereas, only two mothers had survived the eleven Cesarean sections which had been performed in New York up to that time.

This horrible mortality was revolutionized by two factors: namely, the development of antiseptic surgery, and the description by Sänger in 1882 of a proper technic for suturing the uterine incision. The results following their adoption were so striking that Caruso was able to report that in 135 operations performed between the years 1882 and 1888, the mortality had been reduced to 25.56 per cent. Following the employment of more rigid technic and the proper selection of cases, this was gradually lowered, so that at the present time Cesarean section is undertaken by competent operators without hesitation.

When performed either in the last weeks of pregnancy or at the very beginning of labor, its mortality should not exceed that of ordinary gynecologic laparotomies, which is between 1 and 2 per cent. This striking revolution is due entirely to the development of aseptic surgical technic and to the restriction of the operation to uninfected women, who have not been subjected to the exhaustion incident to prolonged labor.

Exactly the same story can be told concerning symphyseotomy and pubiotomy. The former was first performed in 1777 by Sigault, and immediately afterward enjoyed a short-lived popularity, but soon gave such discouraging results that it was abandoned. Harris was able to collect reports of 70 cases up to 1858, with a maternal and a fetal mortality of 37 and 67 per cent., respectively.

The operation was resuscitated in Naples shortly afterward, and between 1866 and 1880, fifty operations were done, with a maternal mortality of 20 per cent. Following the introduction of antiseptic technic, it came into more general use, and Neugebauer in 1893 calculated that the mortality had fallen to 11.1 per cent.; while Mayer in 1908 stated that it had become still further reduced, but was still as high as 6 per cent. In view of the relatively high death-rate, and the more satisfactory results following Cesarean section, the operation gradually fell into desuetude, but was resuscitated again in 1897 under the form of pubiotomy.

Owing to the further development of aseptic technic, and the exact recognition of the character of cases susceptible to it, the mortality of pubiotomy has been kept within low limits, so that in May, 1910, I was able to collect from the literature reports of 518 operations performed by less than twenty operators, with a gross mortality of 1.9 per cent. In my clinic thirty odd pubiotomies have been done with no maternal deaths, while Roth has just reported eighty-five operations from Leopold's clinic with two deaths.

Similar improvement has occurred in the results following all other obstetric operations—forceps, version, induction of labor, *accouchement forcé*, etc. Unfortunately, it must be admitted that owing to the comparative immunity from danger there has developed a tendency on the part of many to resort unnecessarily to operative procedures, when Nature alone would have brought about a happy termination. Notwithstanding such tendencies, however, the general result is most creditable, and stands out in wonderful contrast to that of the past, and has each year been the means of saving the lives and diminishing the sufferings of thousands of women.

In this connection, one cannot reiterate too strongly that all of these advances must be traced back to the same cause, namely, the development of bacteriology and of aseptic surgical technic, both of which in turn are entirely dependent on the employment of animal experimentation.

3. *THE RECOGNITION OF THE BACTERIAL NATURE OF CERTAIN INFECTIOUS DISEASES IN THE NEW-BORN CHILD*

In times past, probably the most important disease of this group, occurring in lying-in hospitals, was the so-called puerperal fever of the new-born child. This condition, which was studied particularly by Schindler, Trousseau, Lorain, Hecker and Bühl, Müller and others, occurred particularly when the hospitals were ravaged by puerperal fever, and was due to the infection of the child during labor, or shortly afterward. In the first case, the amniotic fluid became infected during the course of a prolonged labor with concomitant infection of the air passages of the child with subsequent development of bronchopneumonia; while in the latter case, infection occurred through the stump of the umbilical cord. In either event, the disease was extremely fatal and only a small proportion of the infected children escaped, while autopsy showed one or more of the protean manifestations of wound infection.

Some idea of its incidence may be gained from the fact that a mortality of 7.62 per cent. was observed in the 18,329 children delivered in the Vienna Hospital prior to the work of Semmelweis. Following the employment of the precautions against puerperal fever which he recommended, the fetal death-rate was so markedly reduced that Bednar, who had charge of the Foundling Asylum, stated "that the disease of the children [blood sepsis] had almost entirely disappeared in consequence." Lorain noted a similar connection in the Maternité of Paris and reported that in 2.567 labors occurring during the year 1854, 5.7 per cent of the mothers and 7.5 per cent. of the children were lost, and the high mortality continued until antiseptic precautions were introduced by Tarnier. Hugenberger, likewise, estimated that the average fetal mortality in the St. Petersburg Hospital was 2.6 per cent., which rose as high as 14 per cent. during puerperal fever epidemics; while Hecker and Bühl observed an even higher death rate.

At the present time this condition is observed but rarely, and then only in the case of women who are admitted to the hospital already infected, when the bacteria contained in the amniotic fluid gain access to the child and give rise to infection.

As long as epidemics of so-called fetal puerperal fever occurred, comparatively little attention was paid to the actual mode of infection, but with the subsidence of the disease, the question was more carefully studied. It was then found that the portal of entry was usually through the stump of the umbilical cord, and this type of infection persisted for several years after puerperal fever had practically disappeared from lying-in hospitals.

Occasionally it caused a terrible mortality, and Paquy refers to the experience of Meynet, who lost 17 per cent. of the children cared for in a crêche in Lyons. Moreover, Runge stated that he had observed a mortality of 4 per cent. in Strassburg, as well as nineteen deaths in the Charité in Berlin during the first six months of 1880. His investigations showed that the umbilical arteries were usually involved, while infection occurred only exceptionally through the vein.

Following the introduction of antiseptic methods in caring for the stump of the umbilical cord, this variety of infection rapidly disappeared, so that at present in well-regulated hospitals it occurs only once in many hundred cases. We now hold that the condition always results from bacterial invasion, which is usually streptococcic in character; and we are forced to attribute the great diminution in its occurrence to the recognition of its true nature, which was made possible only by the development of bacteriology, which is based on animal experimentation.

Formerly, large numbers of new-born children died each year from tetanus, and Collins stated that during his mastership at the Rotunda in Dublin, one-fifth of all children, dying within the first fortnight after delivery, perished from it. He also referred to the epidemics observed during the mastership of Dr. Clarke, who said "At the conclusion of the year 1782, of 17.650 infants born alive in the hospital, 2,944 died within the first fortnight, and nineteen out of twenty of these died of nine-day fits." This indicates a total fetal mortality of 16.6 per cent., of which 95 per cent. was due to tetanus. This epidemic was held in check by the greatest attention to ventilation and cleanliness, but that the disease was not entirely eradicated is shown by the experience of Collins forty or fifty years later.

Similar epidemics have also been noted in other parts of the world, one of the most remarkable having occurred in the Island of St. Kilda, and was described by Mitchell in 1865. In this epidemic, 67.2 per cent. of all new-born children died, and the horrible death-rate continued until antiseptic methods of caring for the cord were introduced, when Turner reported that dusting the stump with iodoform had led to its complete disappearance. Until comparatively recently, the negro race in the South was often decimated by tetanus neonatorum, and the extent of its ravages may be gained from the following quotation from Grier:

> We have known more than one instance in which, of the births for one year, one-half became the victims of this disease, and that, too, in spite of the utmost watchfulness and care on the part of both planter and physician. Other places are more fortunate, but all suffer more or less, and the planter who escapes a year without having to record a case of trismus nascentium may congratulate himself as being more favored than his neighbors, and prepare himself for his own allotment, which is surely and speedily to arrive.

Similar conditions likewise obtained in Jamaica, and as early as 1835 Maxwell reported:

> From observations I have made for a series of years, I found that the depopulating influence of trismus neonatorum was not less than 25 per cent. It scarcely has a parallel on the bills of mortality.

Prior to the isolation of the tetanus bacillus, the condition was attributed to filth and impure air, but with the recognition of its specific cause and the employment of aseptic methods in the treatment of the umbilical cord, it has practically disappeared, and in more than 10,000 newly born children under my supervision I have never encountered a case. This advance, just as all the others to which I have referred, must be attributed solely to the employment of animal experimentation, for without its aid the tetanus bacillus could not have been isolated, nor its characteristic pathogenic properties demonstrated.

4. THE BIOLOGIC TESTING OF ERGOT

This drug, which is now so freely employed throughout the civilized world for the control of postpartum hemorrhage by the stimulation of uterine contractions, was first described medically by Dr. John Stearns of Waterford, N. Y., in 1808; while we owe the first dissertation on its physiologic action to Prescott of Boston in 1822. Following this, its complicated constitution has given rise to almost countless investigations, and pharmacologists are not yet in agreement concerning its active principles.

Some of the most important contributions to the action of the drug we owe to Kobert, Jacoby, Grünfeld, Barger and Dale. Ever since its employment for medicinal purposes very conflicting statements have been made concerning its active principles and physiologic action, and it was not until after the careful studies of Grünfeld that the cause for the discrepancy was recognized. He found that the powdered drug rapidly lost its medicinal properties; and while a certain preparation might be very potent when first prepared, it so rapidly deteriorated as to be practically without physiologic effect after being kept for four or five months. The recognition of this fact led to the necessity of devising some method for testing the physiologic activity of the various preparations of ergot before putting them on the market.

Unfortunately, no method of chemical analysis or assay has as yet been devised to enable manufacturing chemists or physiologists to determine the value of a given preparation, so resort was necessarily had to biologic or physiologic tests for the purpose. *From the earliest* times it had been noted that an efficient preparation would lead to marked bluing, and eventually to gangrene of the comb and wattles of the rooster; although later investigations tended to show that such a result was not necessarily an index of its action on the uterus, as it had been demonstrated that the gangrene-producing properties were quite independent of those causing uterine contraction. Consequently, other modes of investigation became necessary. Kurdinowski determined its physiologic activity by testing its effect on the isolated uterus, Kehrer, instead, used thin slices from the uterus of freshly killed pregnant animals, while Cronin and Henderson studied in animals its effect on the blood-pressure.

According to Crawford, most manufacturing chemists at the present time test its efficiency on the cock's comb and wattles; although he states that it would be preferable to employ the living uterus, as recommended by Kurdinowski and Kehrer. In any event the manufacturing chemist must resort to some such form of animal experimentation in testing every specimen of ergot which he uses for the manufacture of the preparations sold to the public; and that means that no woman can take ergot for the control of hemorrhage without being the recipient of at least one of the advantages which has been gained from animal experimentation.

5. *THE DEMONSTRATION OF THE INTERNAL SECRETION OF THE OVARIES*

Although the atrophic changes occurring in the internal genitalia following the menopause, or the operative removal of the ovaries, were long ago recognized, the possibility that they were a manifestation of the disappearance of an internal secretion, formerly elaborated in those organs, was not suspected until after the appearance of Brown-Séquard's suggestive article on the subject.

As long as such a supposition was not supported by facts capable of demonstration, it was not possible to be sure of its correctness, or to deny that the changes in question were neurotic in origin. The experimental work of Knauer, Gregoriff, Mandl and Bürger, Marshall and others, however, conclusively demonstrated that the ovaries elaborate a definite secretion, which serves to regulate the nutrition of the internal genitalia, as well as to exert a definite effect on the entire organism. Moreover, it was clearly shown that the organs could be removed from their usual site and transplanted to other distant portions of the body, and still prevent the degenerative changes which usually follow their removal. As all nervous connections had been severed at the time of operation, it was evident that the only manner in which such an influence could be exerted was by means of an internal secretion, which gained access to the blood-current.

Other experiments showed that the transplanted ovaries functioned perfectly, and if implanted in a suitable location, produced ova which could be fertilized. Such findings were not merely of scientific interest, but possessed a distinctly practical bearing in that they suggested the possibility of transplanting the ovaries in human beings, as well as the employment of ovarian tissue extract in the treatment of various conditions resulting from imperfect ovarian secretion, more particularly the distressing symptoms which frequently accompany the menopause or follow the removal of the ovaries. Not a few operators, when obliged to remove both tubes and ovaries on account of disease, have implanted *healthy portions of the latter* on the uterus or broad ligaments, in order to prevent the occurrence of an artificial menopause in young women. Less frequently, the ovaries of one woman have been implanted into *another, in the hope* of reestablishing the menstrual function, or even making possible the occurrence of pregnancy. The former result has been attained in numerous instances, while the latter has resulted successfully in at least two cases. Those who are interested in the subject are referred for details to Martin's article which contains full references to the literature up to 1908.

Fraenkel, in 1903 and 1910, published two important contributions on the function of the ovaries, which were based entirely on animal experimentation. He apparently showed that the corpus luteum should be regarded as a temporary gland which produces an internal secretion, whose function, at least in part, is to bring about the changes in the internal genitalia necessary to permit the implantation of the fertilized ovum. Furthermore, his experiments rendered it probable that the continuance of the secretion was essential for the preservation of pregnancy during its early periods, but was not necessary later; and thus afforded an explanation for the clinical observation that removal of the ovaries early in pregnancy is usually followed by abortion, whereas their removal later has no effect.

6. *EXPERIMENTAL STUDIES CONCERNING THE NATURE OF THE TOXEMIAS OF PREGNANCY*

Up to twenty years ago our ideas concerning the nature and etiology of eclampsia were but little clearer than in 1843, when Lever first described the presence of albumin in the urine of eclamptic women, and held on that account that it was merely a variety of nephritis.

Following the experiments of Rivière in 1888, and those of Tarnier and Chamberlent a few years later, in which it was apparently shown that the toxicity of the urine of eclamptic women was greatly decreased for experimental animals, while that of the blood-serum was markedly augmented, the belief gained ground that the condition was toxemic in character, and was due to the retention within the organism of certain substances which were ordinarily excreted through the kidneys. Following these observations, the experimental study of eclampsia has occupied the attention of large numbers of investigators, and although the subject has not yet been thoroughly elucidated, the conviction is growing stronger and stronger each year that the disease is a toxemia, which is in some way dependent on the pregnancy, and in all probability connected with abnormal processes either within the body of the fetus or placenta.

It would carry us too far afield to attempt even to enumerate those who have taken part in such investigations, but the contributions of Volhard, Veit, Hofbauer, Lichtenstein, Freund, and Thies deserve especial mention. Moreover, we might refer, in this connection, to the fact that it is only by means of animal experimentation that we have learned the part which the secretion of the thyroid gland plays in regulating the metabolism of pregnancy.

Although none of these experimental investigations have entirely cleared up the etiology of the affection, they have nevertheless served to impress on us its toxemic nature, and have taught us that the treatment *par excellence* consists in the prompt evacuation of the uterus. Moreover, I consider that if the matter is ever to be settled, it can only be accomplished by the aid of animal and biochemical experimentation.

7. THE EXPERIMENTAL PRODUCTION OF FETAL DEFORMITIES

If it is permissible to designate as animal experimentation the various procedures to which the fertilized eggs and the developing embryos of various animals are subjected for the purpose of producing anomalies of development, we can point to a field which has not only markedly advanced our knowledge concerning the normal mechanism of growth and the mode of production of monstrosities, but one which is destined to add greatly to the comfort of the human race.

In times past, the birth of monsters or of children afflicted with congenital deformities was attributed to the anger of the gods, to witchcraft or to some malign influence to which the pregnant woman had been subjected. With the advance of knowledge and the passing of superstition, such views gradually disappeared; but, on the other hand there is scarcely a woman in America at the present time, who does not firmly believe in the doctrine of maternal impressions, and who, in case of the birth of a monstrous or deformed child, will not attempt to trace its origin to some unpleasant sight or experience to which she had been exposed during pregnancy.

Persistence in the belief in maternal impressions is each year a source of great unhappiness to thousands of women, who, after some trivial occurrence, such as seeing a mouse or a rabbit, are convinced that their child will be "mouse-marked" or hare-lipped in consequence, and who do not dismiss their fears until a perfectly normal and well-formed child has been born. Indeed, I feel that I am safe in stating that no one who has not considerable experience with pregnant women can appreciate the extent of the suffering and dread resulting from this superstition.

The new science of experimental embryology and teratology has shown clearly that such an occurrence is impossible, as in the vast majority of cases, the changes which were attributed to it developed in the earliest periods of pregnancy, whereas the "maternal impression" to which a given deformity was attributed did not occur until a much later date.

Geoffroy Saint-Hilaire, Allen Thompson and Féré were the first investigators to attempt the production of deformities by subjecting the developing egg to various influences, but it is only within the last twenty-five years that the matter has seriously engaged the attention of scientific men. During this period, however, the work of Pflüger, Dareste, Roux and Born has put the subject on a scientific basis, as they have shown beyond question that pricking certain portions of the segmenting ovum with a needle, encircling it with a ligature, or subjecting it to certain chemical influences, will inevitably be followed by definite deformities, and they were enabled in this way to produce at will, not only single, but double monsters of the most varied type.

Further research along these lines has been particularly prolific in this country, and the investigations of Loeb, Morgan, Wilson, Bardeen, Harrison, Stockard and many others, has led to most astounding results, which have revolutionized our ideas of teratology. These investigators have shown beyond peradventure that practically all of the deformities with which we meet at the time of labor can be produced at will by subjecting the early ovum or embryo to various procedures. Thus, it is possible to produce spina bifida, cyclops, headless or double monsters, as well as those lacking extremities or having accessory ones, merely by changing the experimental conditions.

As the result of these investigations, it has been definitely proved that, with the exception of certain well-marked hereditary deformities, the great majority of monsters are the result of some interference with the normal growth of the ovum in the days immediately following conception, and not to later influences.

Indeed, at the present time the evidence available seems to indicate that the entire doctrine of maternal impressions is a superstition which will sooner or later entirely disappear, and this result will be hastened as the work of the experimental teratologist becomes generally known.

CONCLUSION

In conclusion, it may be said that while the benefits which obstetrics have derived from animal experimentation are not immediately apparent, they are nevertheless very real, and have led to revolutions in obstetric practice and to results which are but little realized by the general public. I think that I am safe in asserting that had animal experimentation led to nothing more than the discovery of the bacterial nature of puerperal fever, whereby a means was provided for doing away with its former hideous mortality, it would abundantly justify the sacrifice of all the animals which have thus far been used for experimental purposes. Think of the millions of lives which have been saved, if we accept Boehr's calculation, that formerly every thirtieth married woman was inevitably doomed to perish from puerperal infection. Fortunately, this is not the only benefit even in obstetrics, which can be ascribed to animal experimentation, as the increased security following operations and the marked decrease in the mortality of new-born children are equally attributable to it. Indeed, it may be truthfully said that every time a physician cleanses his hands preparatory to attending a woman in labor, he is rendering a tribute to animal experimentation; although unfortunately, the world at large, which benefits from it, does not recognize its significance. I feel that there is every reason to expect that animal experimentation will play as large a part in developing our ideas in the future as in the past, and I confidently believe that the problem of eclampsia and the other toxemias of pregnancy, as well as the cause of labor and all that that implies, will eventually be solved by its means.

1128 Cathedral Street.

Prognosis in Neurasthenia with Gastralgia.—The prognosis is largely one of neurasthenia itself. Remove the cause and the associated gastric pain and disturbance will gradually disappear. No patient with neurasthenia is rapidly cured. Even the all-potent mental effect on the patient of the inspiring personality of doctor or nurse, or the firework impressions of electrical treatment, such as high-frequency, however much they may conduce to the patient regaining hopefulness of cure, cannot result in a rapid recovery. The disease is a slow undermining and weakening of neurons and the cure is a gradual reconstruction and strengthening, which are greatly aided, it is true, if the sufferer can be persuaded that he is on the way toward health once again.—R. A. Fleming, in the *Practitioner*.

TREATMENT OF STUTTERING

E. W. SCRIPTURE, Ph.D. (Leipsic), M.D. (Munich)
Associate in Psychiatry in Columbia University
NEW YORK

As "stutterers" we designate individuals showing certain peculiarities of speech. One stutterer, for example, will make spasmodic contraction of the lips, tongue, etc., whereby a word like "berry" will be pronounced "b-b-b-berry." Another will open his mouth wide and produce an "a-a-a-a-" before he can say a word. Another will find himself suddenly unable to speak at all at the beginning or in the middle of something he wants to say. Still others are quite unable to speak certain words; one young man could never speak the name of his town and was obliged always to buy his railway ticket to the next town beyond; one lady would find herself at a ticket office suddenly speechless and unable to tell what ticket she wanted, while an impatient crowd of commuters gathered behind her.

"Stuttering" is sometimes called "stammering"; the words in English mean exactly the same thing. The word "stammer" is superfluous; it should be avoided because it leads to confusion with the German word *Stammeln,* which means lisping, and not stuttering.

Laryngeal cramps are a never-failing symptom of stuttering. The muscles in and around the larynx become tense and fixed. The tone from the larynx is always monotonous and hard, and it is often husky. It is not unusual to find a patient who never has any other symptom in the presence of the physician except the monotonous laryngeal tone. This most fundamental of all the symptoms of stuttering seems to have escaped all writers on the subject.

Cramps and spasms of the muscles of enunciation (lips and tongue) are the ones most apparent to the observer. The lips may be pressed tightly together for a short or a long time when the patient tries to say "p" or "b." In other cases they will open and shut, producing a series of "p"s or "b"s instead of one. The tongue may be pressed so tightly against the palate that the "t" or the "d" is two, three or ten times too long. All the sounds may be similarly affected.

Less frequent, but more striking, are the contractions of muscles not usually used in speech. One patient will twist his head whenever he stutters badly; another will screw up one eye; another will contort his whole body, etc.

An *almost constant symptom* is excessive rapidity of speech. In some cases this is to be attributed to the desire of the stutterer to get his words out before he is caught, or before any one can interrupt him. In most cases it is the expression of nervous anxiety.

A never-failing symptom is the *patient's lack of confidence* in his ability to speak correctly. In some cases the mere thought "Shall I be able to say that word?" is *sufficient* to make it absolutely impossible for the person to say it. The stutterer always lives with the fear that his speech may "go back on him." Many a one is always thinking a few words ahead of what he is saying, being on the lookout for some word he thinks he cannot say. When such a word is coming, he avoids it by selecting another that will serve just as well. One patient passed his life, practically, in always avoiding words; this mental work added to that of a normal man kept him in a condition of nervous prostration.

The simplest form of stuttering is that of "pure habit." Such a case occurs *rather frequently* in instances in which a younger child unintentionally copies the stuttering of an older one. If the stuttering does not go beyond the stage of pure habit, the younger child drops his stuttering involuntarily when the older one is removed or cured.

The stutterer nearly always goes beyond the habit stage. People laugh at him, *mock him, scold him,* threaten him with punishments, or whip him. Usually he is *obliged* to repeat words he stumbles on. He is made to go through reading and speaking exercises. Extra hard words are given him to practice on. Speaking becomes a torture for him. A new element, the "fear of displeasing and of appearing ridiculous," produces the "fright stage." The stuttering is now a distinct psychoneurosis that may have the most far-reaching consequences.

The *curative treatment* of stuttering is based on the following principles:

The "principle of a new method of speaking" is founded on two facts; first, that the stutterer always speaks in an abnormal voice, which we may call the "stutter voice"; and, second, that he does not stutter when he expresses his ideas in any other voice, such as the singing voice.

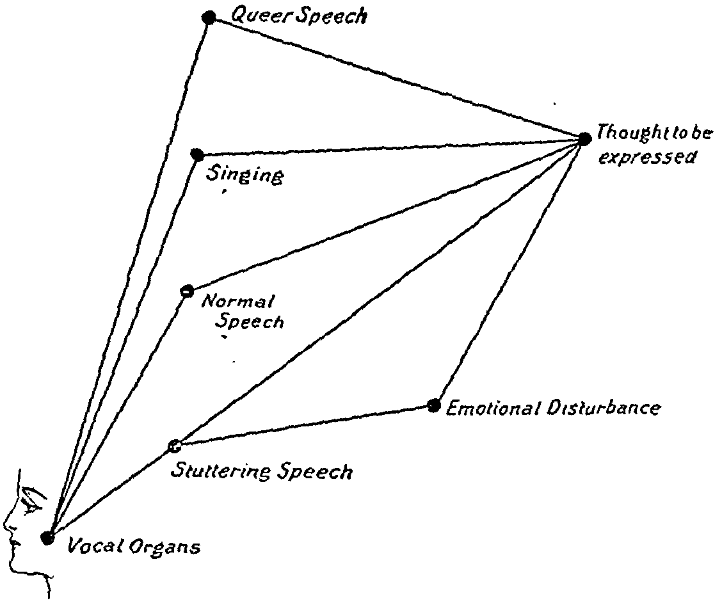

Diagram showing how [illegible] interfere with attempts at normal speech, [illegible] employment of an unnatural voice—queer [illegible] ifficulty and the person does not stutter, because the attention is distracted by the attempt to sing or employ queer speech.

The scheme shown in the illustration expresses these two facts. When the stutterer tries to express a thought in his usual way, *the action of his speech is interfered* with by the emotional condition—embarrassment or fear —that is aroused at the same time. He, *therefore,* speaks in his stutter voice. If he tries to express the thought in any other way than the usual one, the emotional disturbance does not arise. This explains the familiar fact that a stutterer never has any trouble when he sings what he wants to say.

Since the patient does not stutter if he speaks in his usual way, he can be taught to speak in some kind of an odd voice. The stutterer can at any time speak without stuttering, if he will use an abnormally low voice, or an abnormally high one, or if he will drawl the vowels or slur the consonants, or again if he will speak in a choppy staccato voice, and so on. These are the methods of the "stammer-schools" and "stutter-curers." They are objectionable because they leave the patient with a queer voice; people often tell him that the cure is worse than the disease. The patient usually gives up the queer voice after a while and becomes a stutterer again because the queer voice itself produces embarrassment and he naturally feels like discarding it.

The essential point is that the stutterer should feel his acquired speaking voice to be different from his stuttering voice. One patient could never dictate to his stenographer. I found that he could not distinguish one note from another in music; so I told him to sing what he wanted to dictate. He did so without the slightest hesitation or difficulty, in what he supposed to be a singing voice; it did not differ, however, from his usual voice, except in being slightly easier and more natural. As long as he thought he was singing he did not stutter, although he did not really sing. The cure was a failure because he refused "to make a fool of himself by singing to his stenographer." To inform him of the fact that he did not sing would have destroyed the belief that he was singing and would have made him a stutterer again. There was no way out of the dilemma.

There is another way of speaking which is unusual to the stutterer, namely, the way in which normal persons speak. When he speaks in this way, he does not and cannot stutter. The therapeutic procedure on this principle will, therefore, be to teach him to speak normally. The various abnormalities will disappear when the patient has thoroughly learned the exercises below.

The "principle of habit-formation" implies that the new way of speaking is to be drilled into the patient till it becomes a habit.

The "principle of spontaneity" is requisite because, when the patient has learned to repeat perfectly, he will still be unable to do so when he speaks of his own accord. A gradually increasing amount of spontaneous speech is introduced into the treatment.

The "principle of increasing embarrassment" arises from the fact that, even when the patient has learned to speak perfectly in the presence of the physician or the instructor, he is unable to do so under other circumstances. The patient is taught to speak properly before a few persons or before a class. Still more difficulty is introduced by making introductions, speaking over the telephone, buying in stores, reciting in school, etc. For the introduction exercise the stutterer practices at first privately and then with a gradually increasing number of strangers.

The "principle of correct thinking" indicates that the abnormal habits of thought, which a stutterer always acquires to a greater or less degree, are to be corrected by appropriate exercises. A frequent abnormality is that of getting into a daze at each effort to think. The patient finds that he cannot decide promptly. It was typical of one patient that on being asked "Which kind of dog do you like best?" he hesitated and grunted, and finally said, "I really cannot say which I like best." He was cured by being obliged to give some kind of decision quickly, regardless of whether it was correct or not. The trouble was due to the mental flurry or daze that had become a habit. Another patient, when leaving a house, found himself unable to say "Good-bye" because some friends were waiting for him. The trouble arose from a conflict between the motive to hurry after the friends and the motive of not offending the host; this produced a mental daze that left the patient speechless.

The following exercises present an outline of treatment that may be abbreviated as desired. Each step of each exercise is to be repeated a number of times. The exercises are to be repeated as often as may be needed.

EXERCISE I. BREATHING IN PREPARATION FOR SPEECH

A. The patient raises the arms fore upward inhaling and lowers them side downward exhaling. He repeats this and each of the following at least four times.

B. He raises the arms side upward inhaling, and lowers them side downward singing "ah."

C. Likewise with the other vowels.

D. The patient raises the arms upward inhaling; lowers them side downward singing "ah" on middle C and upper C (over the octave).

E. Likewise singing words of one syllable.

The object of this exercise is to develop consciousness of breathing and to form a habit. It also teaches the "octave twist."

EXERCISE II. FLEXIBILITY

A. The patient sings the vowel "ah" on each note of the octave.

B. He strikes the lowest note of the octave and then the highest; sings the vowel "ah" half on the lowest note, half on the highest.

C. He sings the vowel continuously (*portamento*) up the octave. He should note the "fog-horn" effect, the "octave twist."

D. He practices singing the different vowels up the octave in this way.

E. He sings a series of words with long vowels, running the vowels up in the same way.

F. The instructor speaks a word with the octave twist. The patient repeats it.

G. Same with a sentence, putting the octave twist on the first important vowel.

H. Same with a poem, putting the octave twist on the first important vowel in each line.

I. Same with prose, putting the octave twist on the first important vowel in each phrase.

J. The instructor speaks sentences and questions with the octave twist. The patient repeats the sentences and answers the questions.

The object of this exercise is to break up the hard monotonous laryngeal tone. It alone makes the voice normal when it is skilfully done, because it is impossible to stutter and to use the octave twist at the same time.

EXERCISE III. READJUSTING THE VOWELS

A. The patient speaks each of the vowels in a long drawn out tone, going over the octave, e. g. "a-h, o-h, etc."

B. He speaks a short sentence, omitting all the consonants but lengthening the vowels; for example, the sentence "A snow storm is here" will be spoken "A- o- or- i- ere-."

C. He repeats the same sentence, lengthening the vowels and putting in the consonants only faintly.

D. He learns to read and converse in this way.

The object is to teach the patient to weaken the consonants and to speak slowly.

EXERCISE IV. SMOOTHNESS

A. Repeat sentences making every important vowel at least three times as long as usual. These vowels should be spoken with the octave twist. The words are to be linked together, that is, there are to be no pauses or interruptions. The method may be indicated in this way: "Thesu---nisshi---ningbri---ghtly."

B. Questions and answers and short sentences are to be spoken and read likewise.

The object of this exercise is to teach the patient to shorten the consonants, as these are the sounds that cause him difficulty. At the same time it teaches him to speak smoothly and easily. These are factors in forming a voice that is both normal and new.

EXERCISE V. SLOWNESS

With a metronome beating fifty-four times a minute, the instructor and patient read, repeat sentences, ask and answer questions, etc., putting one syllable on each beat. A breath is to be taken before each sentence; all the vowels are to be lengthened and the consonants to be weakened, as described in the preceding exercise. The first important vowel in each phrase is to have the octave twist as described in Exercise II. The whole sentence must be spoken smoothly and softly without the slightest jerkiness. The object is to force the patient to speak slowly.

EXERCISE VI. REGULATION OF BREATH IN SPEAKING

The instructor and the patient are to hold sticks. Each time before speaking, the stick is to be raised sharply while breath is taken vigorously. After waiting one second with bated breath, the person speaks.

A. The instructor speaks a short sentence; the patient repeats it.

B. The instructor asks a question; the patient answers it.

C. The instructor assigns a topic on which the patient is to say something. The patient must raise the baton and draw breath before each statement.

D. The patient is required to give a description of some object in the room in a similar way.

This exercise is needed only when the patient has difficulty in breathing before each sentence.

EXERCISE VII. STARTING A SENTENCE

A. The patient sings short sentences, striking a note on the piano as the first syllable is sung. Instead of using the piano, he may strike a bell or a table or hit his knee or make a gesture as in beating time.

B. He repeats the same sentences, with the same accompaniment in the same way, but singing only the first word.

C. He speaks them with the same accompaniment on the first syllable.

D. Question and answer are sung with the accompaniment on the first syllable.

E. As before, but only the first syllable is sung, the rest being spoken.

F. As before, but all spoken.

G. The patient tells a story, singing the first word of each sentence with the accompaniment.

H. He tells a story without singing but accompanying each first syllable.

This exercise is needed only when the patient has special difficulty in starting. The accompaniment is to be gradually eliminated.

EXERCISE VIII. DEVELOPING EXPRESSION

A. The instructor repeats some poem with expression; the patient repeats it line by line, exactly imitating the expression.

B. The instructor states a certain fact in a very melodious and expressive way; the patient repeats it exactly.

C. The instructor gives a question as in B; the patient repeats it exactly.

D. The instructor gives a question in a very melodious and expressive voice; the patient answers it by taking a few words from the question.

E. The instructor gives a question as before; the patient answers freely, but with the same melody and expression as in the question.

F. Poems and prose pieces are recited with proper expression.

G. Dialogues are read with the proper change of expression for each character.

H. Jokes are read and spoken with an effort to give the most effective expression.

During these exercises no correction of faults is to be made. The entire attention is to be concentrated on the correct expression

EXERCISE IX. CONFIDENCE IN READING

A. The instructor and the patient are to read poems together. Then they are to read alternate lines together and alone.

B. Same with sentences.

C. They are to read a prose speech together, but the instructor is to remain silent occasionally.

D. The patient is to read a prose piece, but the instructor is to join in at the first intimation of difficulty.

E. The patient and the instructor are to read sentences and questions from a traveler's manual, sometimes together, sometimes alone.

F. The instructor and the patient are to read parts in a drama, the instructor joining in whenever the patient has difficulty.

G. The patient is to read a paragraph and then tell its contents in his own language.

EXERCISE X. CONFIDENCE IN SPEAKING

A. The patient calls out railroad stations with a megaphone; the voice must be clear and decided.

B. Same without the megaphone.

C. The patient makes geographical statements with and without the megaphone; for example, "The Atlantic Ocean is east of the United States."

D. He makes historical statements likewise (that is, with and without the megaphone); for example, "George Washington was the first president of the United States."

E. Question and answer likewise.

F. The patient relates a story or an incident likewise.

G. He makes a speech likewise.

H. He takes part in a debate likewise.

I. He takes part in a continuous story which is arranged as follows: One person tells a story which he makes up as he goes along; he suddenly stops and the next person is immediately to continue the story according to his own ideas; he, in turn, suddenly stops and the following person continues. This is kept up until the story reaches the first person.

J. A topic is assigned; the patient prepares a short speech to make on it and delivers it in the presence of the instructor.

K. Same in the presence of several people.

L. A speech is made impromptu on a given topic in the presence of the instructor.

M. Same in the presence of other people.

The number of the people is to be gradually increased until the patient feels ready to get up at any moment and make a short speech on any topic.

EXERCISE XI. CONFIDENCE IN BUYING

A. The patient with a number of objects before him is supposed to be a store-keeper; other people (or patients) go to the store, inquire about articles, discuss the prices and buy. This must all be done with proper attention to slowness and melody of speech.

B. The patient takes the part of the buyer.

C. The store is turned into a railroad ticket office with the patient alternately as ticket agent and as traveler. Various questions concerning trains, accommodations, etc., are to be asked.

D. The ticket office becomes the box office at the theatre; the questions are to include location and seats, exchange of tickets, etc.

E. When the patient can do this perfectly, the instructor accompanies him on actual purchasing expeditions to the stores.

EXERCISE XII. SCENES FROM LIFE

A. A group of people is supposed to be in some familiar situation; for example, eating at a restaurant, riding in an automobile, forming a box party at the theatre, etc. The instructor works out the situation by description, while all persons present, including the patient, make the appropriate remarks. For example, if the scene is at the restaurant, the instructor takes the part of the waiter while the other persons order what they wish to eat, discuss the bill of fare, etc. If the scene is at the theater, the instructor tells a story of the play while the persons discuss the incident, the house, their neighbors, etc. In the automobile party, the instructor takes the part of the chauffeur while the party travels to various places and discusses what has been seen.

B. Similar scenes are worked out, the patient taking the leading parts.

C. The group of persons is supposed to represent a club, the instructor occupying the chair. Various members are to make motions and discuss them, officers are to be elected, etc.

D. The patient is made chairman of the club.

EXERCISE XIII. SPONTANEOUS SPEECH

A. The patient says some word referring to an object placed before him pointed out; the word must have some application to or connection with the object. For example, concerning a book, he may say "large" referring to its size, or "black" referring to its color, or "read" referring to its use, or "table" referring to its position, or "yesterday" referring to something it reminded him of, etc.

B. He makes a statement slowly and melodiously concerning some object placed before him or pointed out to him.

C. He names the objects he sees on one side of the room, proceeding systematically from left to right and speaking slowly and melodiously.

D. He describes an object placed in front of him, using single words and proceeding systematically; for example, if a telephone is placed before him he will first use words referring to its appearance, then to its use, then to its faults, then to its history, etc. He should always adopt some such system in selecting words.

E. Same as D, but complete sentences are to be used instead of single words.

F. Short sentences are to be spoken concerning objects not seen but more or less familiar; for example, breakfast, a distant city, George Washington, Atlantic Ocean, etc.

G. A more extended account is required concerning similar objects as in F.

H. Some or all of the preceding exercises are to be carried out in the presence of additional people.

I. When this can be done perfectly, the patient is to be called on to make short speeches on any topics that may be given him.

J. He is to make speeches on topics of his own choosing.

The object of this exercise is to remove the daze—mental cramp—which many stutterers have when they begin to speak.

EXERCISE XIV. THINKING

A. The name of an object is called out. The *patient* calls out the name of some other object that suggests itself to his mind. If he is in doubt what to say, he chooses some object that is often seen together with the one mentioned. For example, on hearing the word "horse" he replies "cart." This process is called "association of ideas." For the present the patient is to associate deliberately, taking as much time as he wishes. He practices for several times with words like the following:

hand, foot, hair
shoe, glove, eye
coat, sock, motor

B. On hearing each of the words just used, the *patient* makes a sentence about it. It does not matter what the sentence states.

C. On hearing each of the words he makes a sentence defining it.

D. On hearing each of the words, he states some fact about the object implying something regarding its location or its use, or something that preceded it, or caused it, or followed it, or resulted from it, or had some relation to it.

E. Starting with any given word he lets the mind bring up a long series of thoughts. These thoughts should not revolve around the original word, but should pass away to other subjects. If necessary the rule may be adopted of obliging the mind to leave the original word within three associations.

The object is the same as in the preceding exercise.

EXERCISE XV. TELEPHONING

A. The patient calls some one on a private telephone, using the system of his town as nearly as possible. He first calls Central and then speaks with the person desired. He is to speak slowly and melodiously.

B. He takes the part of Central and then of the person called up.

C. He repeats A and B in the presence of other people.

D. He does some of the most difficult exercises over the private telephone with the instructor or some other person at the other end.

E. Using the public telephone, the patient puts his finger on the switch so that when he takes the receiver off the hook, the telephone is not connected with Central. Some one sitting beside him takes the parts of Central and the person to whom the patient wishes to speak. He carries out exercises as on the private line.

F. With the instructor close beside him, the patient calls up Central and then some friends; if he has the slightest hesitation the instructor will speak for him.

G. When he succeeds perfectly in the preceding, he tries the telephone independently. The instructor is to criticize his successes.

The fear of the telephone is very marked in most stutterers.

87 Madison Avenue.

THE DIAGNOSTIC VALUE OF THE BUTYRIC ACID TEST (NOGUCHI) IN THE CEREBROSPINAL FLUID *

S. STROUSE, M.D.
CHICAGO

Of the large number of reports on the cerebrospinal fluid which have appeared in recent times, the great majority have been devoted to a study of changes which occur in the parasyphilitic diseases, and perhaps not *sufficient attention* has been paid to the value of routine diagnostic examinations in general hospital practice. Realizing the importance of establishing certain fundamental facts in relation to the newer tests, at the Michael Reese Hospital we attempted to study in a routine manner all the spinal fluids which came to our laboratory for diagnosis, and in this study especial attention has been paid to determining the status of the butyric acid globulin test devised by Noguchi.[1] Noguchi originally advocated his test for use in the diagnosis of cerebrospinal syphilis, general paresis, and of tabes dorsalis, but suggested that inasmuch as it is present in all inflammations of the meninges, it might prove of value in the diagnosis of tuberculous meningitis. The material on which this report is based has come from varied sources, and includes diseases of varied character. Over 150 cases have been studied; but, since many of our cases were from sources which prevented us from following them, this report is based on the ninety cases in which a diagnosis is fairly certain. I regret, however, that the inability to obtain autopsies is a source of error in the interpretation of disagreements between the clinical diagnosis and the findings of the laboratory examination. Furthermore, the series is rather small for very definite conclusions, but the general agreement in our results is sufficiently striking and suggestive to warrant their publication with the hope that more workers in this field will be able to study larger numbers of cases and thus contribute more definite knowledge.

---

[1] Noguchi and Moore: The Butyric Acid Test for Syphilis in the Diagnosis of Metasyphilitic and Other Nervous Disorders, Jour. Exper. Med., 1909, xi, 604.

Although the technical methods employed in all our cases have been constant, the different character of the fluids made it advisable for practical purposes to adopt certain standards of procedure varying with the source of the fluid. For instance, better results are obtained when the spinal fluid from a patient suspected to have tuberculous meningitis is handled in a manner to facilitate the finding of tubercle bacilli, whereas, in those cases in which the examination may aid in the differential diagnosis between functional and organic nervous disorders, special stress is laid on chemical and cytologic aspects. In all cases, the first step employed is a bacteriologic culture on media containing hemoglobin. In cases of suspected tuberculous meningitis one tube of fluid is put untouched in the ice-box, and allowed to remain for at least twelve hours in order to permit the formation of the film which enmeshes the bacilli. As has been emphasized recently by Bybee and Lorenz,[2] practically all workers find the study of the cells most difficult, and no completely satisfactory method, either for the total or the differential count, has yet been devised. My experience with the total cell-count has been that the use of the ordinary red cell counting pipette with methylene-blue, gentian-violet or acetic acid gives results, which, while only partially satisfactory, are at least much better than those from the French method. The differential count is made from the sediment after centrifugalization for a half hour at about 1,800 revolutions, and stained with Wright's stain. In many instances, however, this procedure is eminently unreliable, as it is often impossible to differentiate the various cell types by this method. Far more valuable, in my experience, and much less difficult of interpretation, has been the use of some one of the methods for determining increased globulin content. In a recent careful review of the literature,[3] I found a fairly general agreement in the opinions expressed as to the relative diagnostic value of increased cell-count and increased globulin fraction. In normal fluids the number of cells present is from 0 to 5, 6, or even 8 per cu. mm., whereas the amount of protein is so small as to be unrecognizable by ordinary clinical methods. In all inflammations of the meninges, and in general paresis and tabes, there is an increase of the cells and of the protein. As a rule the increases in these two elements run parallel courses, and likewise the diagnostic significance of the tests is of about equal value. In my series the agreement was almost constant, but the two reactions were not always of equal value.

Numerous methods have been employed for the determination of increased protein, all based on the fact that the increase is due to serum globulin. In all tests the fluid must be free from blood. Nonne's[4] well-known Phase I has not been found to have the delicacy of some of the modifications, owing to frequent difficulties in differentiating a positive from a negative reaction. Ross and Jones[5] have modified the technic of procedure by making a ring test similar to Heller's nitric acid test in the urine. On two parts of a heat-saturated solution of ammonium sulphate in a test-tube they float one part of the fluid and look at the line of junction for the reaction. In positive cases an easily perceptible white line of precipitated globulin appears. Wherever it has been used, this reaction has met favor, and seems to possess about the same delicacy as the Noguchi test, with the possible exception that the line of junction is somewhat more difficult to read than is the Noguchi. This latter test, which is probably the most satisfactory at present, is employed as follows:

> One part (0.1 or 0.2 c.c.) of cerebrospinal fluid is placed in a test-tube, and to this is added five parts of a 10 per cent. solution of pure butyric acid in physiologic salt solution; the mixture is heated to boiling, and immediately one part of normal sodium hydrate added and the mixture again boiled. In the presence of increased globulin a definite flocculent precipitate occurs, either immediately, or within two hours. This definite precipitate must be differentiated from a faint cloudiness which normal fluids may give, but it requires only slight experience to recognize the difference between positive and negative reactions.

Properly to appreciate the diagnostic value of the study of spinal fluids it is necessary to remember that the spinal fluid is, in a diagnostic sense, analogous to the blood, and, as in the blood only a few tests of absolute value are known, so in the interpretation of the examination of spinal fluid most of the knowledge obtained is relative. An increased leukocyte count or an eosinophilia is a pointer of importance only when considered in relation to the clinical findings, and practically the only absolute diagnostic signs are those obtained by finding the specific etiologic agent or one of the few specific bacterial or chemical reactions like the Widal or the Wassermann. In the spinal fluid not too much can be expected, and it is well before discussing our cases to emphasize that only in exactly similar instances can absolute determinations be reached. The finding of the tubercle bacillus or the pneumococcus, or a positive Wassermann are the occasional high lights in routine study of cerebrospinal fluids; a positive Noguchi reaction does not mean any one disease any more than does a leukocytosis mean pneumonia. If, however, it can be shown that the Noguchi reaction is not present in any of the functional neuroses or psychoses, while it is present in certain organic diseases whose symptomatology resembles that of the neuroses, then its value as a diagnostic sign must be recognized; or if it occurs in *tuberculous meningitis and not in the numerous clinical* entities which may simulate this disease in children, it must be admitted into the group of signs which help to make the diagnosis of tuberculous meningitis. It is from the standpoint of relative usefulness that we wish to present the subject, and in doing so it seems better to consider our cases under groups showing similar clinical manifestations.

The first group to be presented is that of cerebrospinal syphilis, general paresis, and tabes dorsalis. It would be a waste of time and space to review here the extensive literature on the changes in the spinal fluid in these diseases. Suffice it to say that the salient features are an increase in the globulin and in total cell-count in about 90 to 95 per cent. and peculiarities in the differential count involving mainly the mononuclears, about the classification of which there is considerable discussion. The figures for positive Wassermann reactions vary from 50 to 95 per cent. The Noguchi and the Ross-Jones tests have proved of greater value than the original Nonne (Amsden,[6] McCampbell and Rowland[7]).

TABLE 1.—CELL FINDINGS AND REACTIONS IN CASES OF CEREBROSPINAL SYPHILIS, GENERAL PARESIS AND TABES DORSALIS

Case No.	Diagnosis	Noguchi	Cells	Wassermann C. S. F.	Wassermann Blood	Ross-Jones
1- 3	Cerebral syphilis	+	..	..	..	..
4-10	General paralysis	+	..	..	..	..
11	Cerebral syphilis	+	+	—	+	+
12	Cerebral syphilis	+	+	..	..	..
13	Tabes dorsalis	+	+	+	+	..
14	Tabes dorsalis	+	+	—	+	..
15 16 17	Same patient, tabes dorsalis	—	..	..	+	..
18-20	Tabes dorsalis	—	—	—	—	—
88	General paralysis (?). Cerebral arteriosclerosis (?)	—	—	—	—	—
21-23	Brain tumor	—	—	—	—	..
24-25	Dementia præcox	—	—	—	—	..
26-27	Cerebral arteriosclerosis	—	—	—	—	..
28	Pernicious anemia with spinal cord involvement	—	—	—	—	..

Table 1 shows our results in this group of cases. It will be seen that in five cases of cerebrospinal lues, and in seven of general paresis, the Noguchi was positive in all. Systematic study of the other reactions was not possible in this series. In two cases of tabes the Noguchi and the cell-count were positive in both, the Wassermann on the blood in both, and on the spinal fluid in one. In one other advanced case (15, 16, 17) of tabes, the Noguchi was negative on three successive occasions, whereas the Ross-Jones test was positive the only time it was tried, and the Wassermann on the blood was twice positive. Cases 18 to 20 were cases of undoubted tabes dorsalis, with typical histories, and at least some of the pathognomonic signs. One was an advanced case and the other two were incipient. In all three cases it is interesting to note the absence of changes in the spinal fluid as well as the negative Wassermann. In Case 88 the history was obscure and the physical findings not definite; the further course of the disease must settle the diagnosis.

In contrast to this series must be placed those cases in which exists the possibility of confusion with the conditions just discussed. In three cases of brain tumor, two of dementia præcox, two of cerebral arteriosclerosis the Noguchi was negative in all, the cell count normal in the four cases in which it was made, and the Wassermann negative on the blood in five. Of especial interest was the patient who presented cord symptoms of pernicious anemia which simulated very strongly those of tabes dorsalis, but whose spinal fluid and Wassermann were entirely negative. Our results in this series are distinctly in accord with those of other workers on the incidence of the butyric acid test in general paresis, cerebral lues, brain tumor and psychoses, but at marked variance in tabes dorsalis. Many more cases are necessary, however, before these few instances can be cited as evidence against Noguchi and Moore's original claim of 100 per cent. positive results.

As far as we are aware, no large series of cases has yet been reported in which advantage is taken of the ease and rapidity of the Noguchi reaction as an aid in the differential diagnosis between acute meningitis and other conditions whose clinical manifestations resemble those due to actual inflammation of the meninges. Apelt[8] has used the Nonne globulin test in differentiating meningitis from meningismus. In children, especially, the state of meningismus is often so pronounced as to puzzle the most able clinician, and not infrequently in the infectious diseases lumbar puncture is the only diagnostic means at our disposal for the solution of the problem. Later we wish to discuss in some detail the special value of the reaction in tuberculous meningitis.

TABLE 2.—ACUTE MENINGITIS AND MENINGISMUS

Case No.	Diagnosis	Noguchi	Cells	Bacteria
		ACUTE MENINGITIS		
29–31	Pneumococcus	+	P. M. N.	Pneumococcus
32–44	Meningococcus	+	"	Meningococcus
45	Streptococcus	+	"	Streptococcus
46	Influenza	+	"	Influenza
		MENINGISMUS		
47	Typhoid	—	—	—
48–52	Pneumonia	—	—	—
90	Pneumonia	—	—	—

In Table 2 can be seen the findings in three cases of pneumococcus meningitis, one of streptococcus and one of influenza meningitis, and in thirteen cases of cerebrospinal fever due to the meningococcus. In all of these, as might be expected from the great exudate of polymorphonuclear leukocytes, the Noguchi test is positive. In the six cases of meningismus occurring in pneumonia, and one in typhoid, the test is negative in all. Of course the clear fluid and the negative bacteriologic findings lead one to expect an absence of globulin, but as the same sort of fluid may be found in tuberculous meningitis, *which in all our cases showed a positive Noguchi, it seems to us to have considerable value in these conditions.*

Until quite recently, when more refined methods for finding the tubercle bacillus were introduced into the examination of spinal fluids, a definite diagnosis of tuberculous meningitis was always beset with more or less difficulty, especially in the early stages. No extended observations have been made on the globulin fraction in these cases. Our results have been constantly positive. Hemenway[9] has tried the test in a few cases with positive results.

TABLE 3.—TUBERCULOUS MENINGITIS

No.	Noguchi	T. B.	Cells
53	+	0	Lymphocytosis
54	+	0	Few lymphocytes
55	+	0	Few lymphocytes
56	+	0	Many lymphocytes
57	+	0	Many lymphocytes
58	+	0	Many lymphocytes
59	+	0	Many lymphocytes
60	+	+	Many lymphocytes
61	+	+	Many lymphocytes
62	+	+	— —
63	+	+	Lymphocytosis
64	+	+	— —
65	+	+	— —
66	+	+	Lymphocytosis
67	+	+	Lymphocytosis
68	+	+	Lymphocytosis
69	+	+	— —
81	+	+	Lymphocytosis

Table 3 shows positive Noguchi reactions in eighteen cases, in the first seven of which the diagnosis was verified by the further clinical course, or by autopsy, and in the last eleven by finding tubercle bacilli in the fluid. It is important to note that our first seven negative bacterial findings occurred when we were using the centrifuge method, while the last eleven positive cases were due to the change to the so-called film method. The technic of this method is so simple and the results so much more satisfactory than any other procedure, that it is advisable to review it in some detail. A tube of the clear or slightly turbid fluid, handled as little as possible, is immediately placed in the ice-chest and allowed to remain there for twelve hours. Most workers put the tube in the incubator, but we have found no difference in results by using the ice-chest, and by its use we are safeguarded from bacterial growth due to accidental contamination—a point which must be considered when fluids come from various sources and are often subject to slightly careless manipulation. At the end of this time a pedicle or a film of varying density generally forms throughout the fluid, and this is floated on to a slide in the same manner as is a piece of tissue. It is important not to mesh up the film; the thinner it spreads and the less tangled it is, the better will be the results. Aftr drying in the air the film is fixed by heat and stained with the usual carbol-fuchsin stain.

[9] Hemenway: The Constant Presence of Tubercle Bacilli in the Cerebrospinal Fluid of Tuberculous Meningitis, Am. Jour. Dis. Child., 1911, i, 37.

These eighteen positive globulin tests, added to the few already reported in the literature (Stillman,[10] Apelt,[8] Ross and Jones[5]), render it fairly certain that the reaction is present as a general rule in tuberculous meningitis. In our series it has been more constant than the lymphocytosis, and it certainly is much easier to perform than is a total cell-count and a differential count.

Many fluids have come to us from patients in whom a tentative diagnosis of tuberculous meningitis has been made, but in whom the later course of the disease proved the diagnosis to be incorrect.

TABLE 4.—CASES IN WHICH A TENTATIVE DIAGNOSIS OF TUBERCULOUS MENINGITIS HAD BEEN MADE

No.	Diagnosis	Noguchi	Cells	Remarks
70	Encephalitis	—	..	....
71	Acute purulent adenitis	—	—	....
72	Tetanus	—	—	....
73	Gastro-enteritis	—	—	Death
74	Uremic coma	—	—	....
75	Poliomyelitis	—	—	....
76	?	—	—	Complete recovery
77	?	—	—	Complete recovery
78	?	—	—	Complete recovery

Nine cases of this nature are shown in Table 4; they include various diseases whose manifestations at the stage in which lumbar puncture was performed resembled those of tuberculous meningitis. In all it will be seen that both the cell-count and the globulin test were negative—a sufficiently strong contrast to the findings in tuberculous meningitis to warrant the statement that a negative butyric acid test is presumptive evidence against the presence of tuberculous meningitis. This cannot at present be stated as dogma, as many more examinations will have to be made before the exact truth can be learned. Again it must be emphasized that the reaction cannot, from its very nature, be specific for tuberculous meningitis, any more than it is for general paresis, and to be of any value at all it must be considered only after the most careful correlation with the history and physical findings.

TABLE 5.—MISCELLANEOUS

No.	Diagnosis	Noguchi	Cells	Wassermann
79	Hydrocephalus	—	—	—
80	Hydrocephalus	—	—	....
82	Anterior poliomyelitis	—	..	....
83	Encephalitis	+	—	....
84	Uremia	—	—	....
70	Encephalitis	—	—	....
85	Uremia	—	—	—
86	Myelitis	+	+	—
87	Myelitis	—	—	—
89	Amaurotic family idiocy	+	+	+

As a further elucidation of this point Table 5, presenting the findings in a series of miscellaneous diseases, is of considerable value. In both cases of hydrocephalus the reaction was negative, although increased globulin has been reported present in this condition by Nonne.[11] In both cases of anterior poliomyelitis it was negative; in one case of encephalitis positive, in one negative; in one case of transverse myelitis positive, and in one negative. In three cases of uremic coma it was negative. In the case of amaurotic family idiocy the positive Noguchi and the positive Wassermann are hard to reconcile with the completely negative examination for syphilis at the autopsy. In considering the nature of the diseases in which the reaction seems to vary so much, it may be explained that all the conditions are such as may produce meningeal involvement and consequently a positive butyric acid reaction. On the whole, the main value of this small series lies in emphasizing that even in clinical conditions which may resemble tuberculous meningitis, a positive reaction does not by any means indicate the presence of a tuberculous inflammation, but a negative one presupposes the absence of such a condition.

CONCLUSIONS

This series warrants the following conclusions:

1. Tests for increased globulin in the spinal fluid are easier to perform than is the total cell-count, and have practically the same diagnostic importance.
2. The butyric acid test of Noguchi is convenient and accurate.
3. The use of this reaction gives information of considerable value in diagnosis.
4. The reaction is positive in general paralysis and cerebrospinal syphilis; negative in brain tumor, cerebral arteriosclerosis and psychoses. A positive reaction in a doubtful nervous case is presumptive evidence in favor of the diagnosis being a syphilitic or parasyphilitic disease of the nervous system.
5. In tabes dorsalis, our results are not in agreement with previous reports, the reaction being present in only 33⅓ per cent.
6. The reaction is positive in all cases of acute meningitis and absent in meningeal irritation without actual inflammation.
7. It is always present in tuberculous meningitis, and its presence is an aid in the diagnosis. The absence of the reaction in cases of suspected tuberculous meningitis is of great value in excluding meningitis.

TREATMENT OF INOPERABLE CANCER OF THE CERVIX

PALMER FINDLEY, M.D.
Professor of Gynecology, College of Medicine State University of Nebraska
OMAHA

Believing as we do that permanent relief from cancer of the cervix comes through the timely application of the knife, we find little enthusiasm in the management of inoperable cases in which the patients at best can be given but temporary relief. When the disease has gone beyond the reach of the knife we say that it is incurable, but our responsibilities do not end here. Months, and perchance years, of comparative comfort may be added to the life of the unfortunate victim.

One cannot review the literature on the treatment of inoperable cancer of the cervix without being strengthened in one's conviction that much can be done in these pitiable cases. We cannot cure these patients, but we can relieve their suffering, inspire them with hope and give them added days of comfort and usefulness.

[10] Stillman: A Report on the Value of Noguchi's Reaction on Spinal Fluids, Proc. New York Path. Soc., 1909, new series, ix, 1.

[11] Nonne: Clinical Diagnosis of the Syphilogenous Diseases of the Central Nervous System, The Journal A. M. A., 1909, liii, 289.

Blau reported 408 cases of inoperable cancer of the uterus in the Chrobak clinic. These patients were treated by scraping and the application of the Paquelin cautery; the procedure was repeated at intervals of three to four months. Subsequent reports were obtained from 342 of the 408 patients. One lived eleven years after the above treatment. One was alive and apparently in good health after nine years and another after six years. There was an average of 252 days of life after the initial curettement and cauterization.

In the cases of Conrad, there was an average of 525 days of life from repeated applications of chlorid of zinc and pyoktanin.

Baker reported fifteen patients living from two to twelve years; Byrne ninety patients living from two to seventeen years; Pawlik twenty-nine patients living from two to twenty-one years after repeated local applications. Tomer reports 213 patients treated with the Paquelin cautery free from recurrence after two years, and of this number 149 were apparently healed after five years.

Mose Madden amputated the cervix with the galvanocautery in twenty-two patients; ten were free of recurrence two and one-half years at the time of publication.

The above statistics could be added to indefinitely, but enough have been quoted to convince the most skeptical that cauterization is worth while. While it is true that these statistics antedate the extended operations, and that in many the diagnosis was not verified by microscopic examination, yet the proof of the value of local applications and of cauterization in particular is not wanting.

No signal advance has been made of late years in the treatment of inoperable cases, and the explanation lies, in part, in the difficulties experienced in their management. Few hospitals will harbor these sufferers for the time necessary to pursue extended observations. The patients are usually admitted for a single application of one remedy or another and in a few days are dismissed. The rich will not remain in the hospital, the poor cannot afford to remain, and the hospital management has no desire to retain either. Tomer and Chrobak pass caustic criticism on the attitude of the hospital management toward these patients and recommend isolated wards for their care. In this connection I am pleased to bear witness to the splendid facilities provided in the Skin and Cancer Hospital of St. Louis and to the recent valued contributions to the subject in hand by a member of the surgical staff.

The great number of inoperable patients who present themselves reflect discredit on the diagnostic acumen of the profession, and call for an organized effort looking toward the enlightenment of the laity to the end that women will seek medical advice when the danger-signals become manifest.

The large percentage of recurrences are not chargeable to faulty technic, for it would seem that in the radical abdominal operation for cancer of the cervix we have all but reached our limitations. The explanation lies rather in the failure to recognize the cases while there is yet time to eradicate the disease completely with the knife. Far too frequently are these patients operated on when eradication of the entire cancerous growth is manifestly impossible. "Operated and operable cases may be, and in reality often are, quite different things" says Koblanck. In this connection, I would express the conviction that were we to follow the suggestion of Rosthorn and Franz in the making of an exploratory abdominal incision in recurrent cases, we would find more encouragement in pursuing such cases with repeated attempts to eradicate the disease. When doubt exists as to the extent of recurrence, an exploratory abdominal incision should be made, and in so doing a certain, though not large, percentage of these patients will be found amenable to surgical intervention who might otherwise be treated along palliative lines.

It requires but a hasty survey of the literature to convince one of the futility of all efforts to stay the progress of the disease when once it has passed the confines of the uterus. Were I to recite the long list of remedies proposed in the last two decades, there would be nothing gained and the space allotted me would be consumed. I shall pass them by without consideration, for they have been weighed in the balance and found wanting. The Roentgen ray had proved of positive value in many of the superficial cancerous growths of the body, and the profession was slow to reject its claims as a curative measure for cancer of the cervix, but it has gone the way of its predecessors and to-day we find ourselves almost as helpless as we were generations ago.

The curette and cautery are still in active service, and I for one am not disposed to discard them, for they have proved of positive value in my hands in providing temporary relief from hemorrhage and foul discharges. Though the disease steadily advances to a fatal issue, we are bound to give credit to these measures for added days of comparative comfort. The results of Blau and others clearly demonstrate the value of repeated applications of the curette and cautery at intervals of from three to four months. Unfortunately, we are seldom privileged to follow up our patients so persistently. A single application will afford relief from bloody and fetid discharges for but a brief time, but the recurrence of these discharges will be longer delayed with each application.

Dr. James Spencer Brown of Mont Clair, N. J., is an enthusiastic advocate of the vigorous application of the cautery. He protects the vaginal walls with thin asbestos, holding the sheets in place by retractors. With the soldering iron he deeply cauterizes not only the cervix but the cavity of the uterus as well.

For the past six years I have followed the practice of Dr. Clarence Webster in packing the excochleated and cauterized area with gauze wrung out in a 1 to 4,000 aqueous solution of 40 per cent. liquor formaldehydi. Following such a procedure bloody and odorous discharges may disappear for from two to four months.

The latest remedy proposed for the relief from hemorrhages and fetid discharges is acetone. We are indebted to Dr. George Gellhorn[1] of St. Louis for its introduction and for extended observations in its application. Results obtained by him speak for the efficacy of the remedy, and it is to be hoped that the profession will join with Dr. Gellhorn[1] in giving it an extended trial. I here quote his description of the technic of its application:

> The treatment should, if feasible, be preceded by a thorough excochleation of the ulcerating area. The curetted cavity or crater is then carefully dried with cotton sponges and from ½ to 1 ounce of acetone is poured into the wound through a Ferguson or other tubular speculum. For this purpose, the pelvis of the patient must be raised as in Trendelenburg's position. The narcosis may now be interrupted and the patient be left in this position for from fifteen to thirty minutes. Next, the acetone is permitted to run out through the speculum by lowering the pelvis of the patient and the cavity is packed with a

---

[1] The Journal A. M. A., April 27, 1907, p. 1400.

> narrow gauze strip soaked in acetone. The healthy mucosa of the vulva and the vagina are cleansed with sterile water and dried.
>
> After this preliminary curetting and cauterization, the regular treatment, which requires no further hospital care, is administered two or three times a week, beginning the fourth or fifth day after the operation. This is done without narcosis and may be given with the patient in bed or on the ordinary examining chair or table in the office. The pelvis of the patient is raised and the tubular speculum is inserted into the cancerous cavity. With the progressive diminution of the crater, smaller specula are gradually employed. The speculum is filled with acetone and held in place by the patient's hand for half an hour, and is then emptied in the manner described above. Care should be taken to prevent the acetone from running over the vulva or perineum.

In a subsequent article[2] Gellhorn states that he prevents the acetone from running over the vulva and perineum by applying a thick layer of ordinary petrolatum to the vulva and lower third of the vagina; then, after the acetone has run out of the speculum, he swabs the cavity dry and introduces a large cotton tampon coated with petrolatum into the vagina before the speculum is withdrawn. This tampon may be removed by the patient after a few hours.

Gellhorn says that slight oozing of blood is checked almost instantly; that offensive discharges become at first watery, then gradually disappear; that the hemorrhages fail to recur if the treatment is faithfully pursued and that in the course of two or three weeks the walls of the crater become smooth and firm, making a second curettement unnecessary. A diminution in the size of the crater was noted in some cases. With the disappearance of the weakening hemorrhages and discharges, the general strength and nutrition improved. There was no control over the pain due to the cancerous invasion of the nerve trunks.

From the experience of Gellhorn and the few others who have contributed to his observations, I am persuaded that we have in acetone a valuable remedy in the treatment of inoperable cancer of the cervix. It has advantages over the curette, cautery and formaldehyd packs when the patient can be kept under the control of the physician. When the case will not permit of constant supervision, I would give preference to the cautery and formaldehyd solution on the ground that a single application of the latter will have a more lasting effect.

At the recent meeting of the American Gynecological Society in Washington, I took occasion to interview many of the fellows of the society on the subject. There was no manifest enthusiasm in their management of these cases. The great majority were in favor of the curette and cautery and advised the vigorous application of the Paquelin cautery after scraping away all necrotic tissue. Kelly holds the cautery at white heat in the excochleated area for several minutes. In this manner the tissues are deeply affected. Far from criticizing the use of the cautery in these cases, the majority spoke for its more vigorous application.

A variety of remedies were recommended after the application of the curette and cautery, e.g., zinc chlorid (Peterson), equal parts of formaldehyd solution and epinephrin together with the chlorid of zinc (Clark), tincture of iodin locally and Lugol's solution internally (Montgomery).

Only three of the men interviewed had tried the acetone treatment and one of these had abandoned it because of technical difficulties involved in its application (Chipman).

It was my impression that the majority of the men interviewed were of the opinion that the curette and cautery would accomplish all that could be done for these patients. Few had given the acetone treatment the consideration it deserves.

Recently Richter[3] gave an account of the work done in Leopold's clinic with the method of fulguration as proposed by Keating-Hart in 1908. The report is not favorable to the method. I note with interest, however, that the acetone treatment of Gellhorn is endorsed most enthusiastically. One patient has received eighty applications of acetone in the past twenty-one months. The vagina was contracted by bands of scar tissue and would admit the index-finger but 2.5 cm. There was a fistula at the vault of the vagina which discharged a slight bloody purulent secretion. The pelvic connective tissue was widely infiltrated. The patient complained of pelvic pain but her general appearance was good. Richter speaks of the acetone treatment as the most satisfactory method ever employed in Leopold's clinic.

As yet, no remedy has approached the desired object —that of destroying the invading cancer cells. We look to the chemist and biologist for the solution of the problem, believing that a vaccine will be forthcoming that will do more than palliate this dread disease—a vaccine that will prevent the development of cancer, that will forestall recurrence and that will stay the progress in inoperable cases.

Note.—Since writing the above I have had the privilege of visiting the new Skin and Cancer Hospital of St. Louis. In this visit I examined several of Dr. Gellhorn's cases of inoperable cancer of the cervix, and saw him treat two of his patients. His results are unquestionably superior to any that have been obtained by methods previously in vogue. In none of his cases did I observe either odor or hemorrhage.

One case was particularly noteworthy. A growth, which filled the vault of the vagina, was curetted about one year ago. Since then the patient has had twenty applications of acetone. When I saw her there was no odorous discharge, no hemorrhage; the vault of the vagina appeared as a puckered scar with a small fistulous opening leading to the uterus. The patient had gained 20 pounds in weight and suffered little or no pain. Unquestionably, her life has been prolonged and made comfortable to a degree that speaks for the inestimable advantage of the acetone treatment.

TREATMENT OF EXOPHTHALMIC GOITER WITH THYROIDECTIN

HUGHES DAYTON, M.D.
Associate Attending Physician, New York Hospital
NEW YORK

Working on the hypothesis that the symptoms of exophthalmic goiter are due to excessive secretion of the thyroid gland, attempts have been made by some to limit the amount of this secretion by extirpating a portion of the gland, by ligating its arteries, and by interstitial injections intended to cause partial atrophy. Approaching the problem from another standpoint, others have endeavored to neutralize the products of glandular hyperactivity by administering milk, blood, or serum of animals whose thyroid glands have been removed, and in which the hypothetical antibodies which normally neutralize the thyroid secretion may be supposed to have accumulated. Still others have employed serums made by injecting into animals normal human thyroid or that of patients suffering from exophthalmic goiter.

Although the wave of enthusiasm which accompanies the introduction of any new remedy seems to have passed, judgment of the value of most of these serums appears to be based on individual reports of one or more cases in which there was improvement during their administration, alone or combined with other treatment, and often with the most important addition of rest in bed. Unfavorable results are always less likely to be recorded than successful cases.

Many writers group the results obtained with various preparations and, giving few data concerning individual cases, draw their conclusions as to "serum-therapy" collectively. Thus, F. S. Bulkeley[1] in a review of the literature of serum treatment of exophthalmic goiter, omitting that relating to the serums of Rogers and Beebe, has collected reports of eighty-six cases. Excluding from these the cases of three patients treated with the blood of a myxedema patient, he records eighty-three cases, with improvement in all but six, and sixteen possible cures judging from data given. This writer groups collectively cases in which Moebius' antithyroidin, serum of rabbits fed with thyroid extract, thyroidectin, serum of a thyroidectomized dog, milk of thyroidectomized goats and a proprietary substance said to be prepared from the milk of thyroidectomized goats were administered; and from these he generalizes as to the effect of "serum-therapy."

Confining our attention to thyroidectin, which is prepared from the blood of thyroidectomized animals, and of which few reports have been published, we find in this list of cases collected by Bulkeley thirty, all of which were pronounced improved, none cured. Since that time A. G. Gullan[2] has recorded five cases, all greatly improved; and H. H. Miller[3] one case in which for eight weeks thyroidectin and iodalbin were administered synchronously, with disappearance of symptoms. The same medication was continued irregularly for three months, and about one year later the symptoms had not returned. These reports include thirty-six cases with improvement in 100 per cent. In contrast, we note the general verdict of A. Kocher,[4] who states that thyroidectin is of inconstant and not of lasting benefit; of E. M. Fisher,[5] who says, "Thyroidectin has proved useless in my hands"; of D'Orsay Hecht,[6] who writes, "Thyroidectin cannot be said to have ever stood approved." Aside from these general condemnations, F. Billings[7] reports the use of from 15 to 40 grains of thyroidectin a day in divided doses in twelve cases with varying results. In none did he secure the favorable results recorded by others. In two cases the symptoms were aggravated by the remedy. This report of Billings is excluded by Bulkeley in his collation of cases up to 1907, which includes thirty cases all improved by the use of thyroidectin, on the ground of scantiness of data and lack of distinct statement of failure or improvement. M. T. Sudler,[8] giving very few data, reports a single case of unilateral goiter with nervousness and rapid pulse treated "medically with the *addition of thyroidectin*," which seemed to improve very slightly and has since remained about the same. S. Gillies[9] has seen improvement in patients taking thyroidectin, but is not sure that suggestion has not much to do with the results.

In the following five cases thyroidectin has been used:

CASE 1.—*History*.—A. T. B., a woman aged 26, single, bookbinder, native of United States, entered New York Hospital (Medical No. 12,120) Feb. 25, 1905. The family history was negative. The patient had had measles, pertussis, scarlatina in childhood; frequent bronchitis; menstruation regular. About 1896 the patient noticed a swelling in central part of neck anteriorly. This slowly increased until 1904; since then there has been no further enlargement. In 1897 the patient noticed that the eyes were becoming prominent, and they continued to do so until 1904. The patient became very nervous; had hysterical manifestations at intervals; has had palpitation of the heart, which was made worse by exertion, as long as she can remember.

Physical Examination.—The patient was fairly well nourished, muscular, with neurotic facies and marked exophthalmos. Von Graefe's sign was present; the patient was unable to approximate the lids completely; there was marked pigmentation of upper lids. There was bilateral enlargement of thyroid; fine systolic thrill over it; loud systolic bruit, loudest over right lobe of thyroid. Cardiac apex-beat in fourth intercostal space, 7.5 cm. to left of median line; sounds clear; systolic murmur at aortic and pulmonic areas, and very faint at apex. The pulse was regular, force fair, tension low. There was slight tremor of hands, especially the right; slight edema of ankles. The lymph-nodes in the groin were enlarged. Temperature, 99 F.; respiration, 20; pulse, 108; red blood-cells, 4,928,000; hemoglobin, 94 per cent. The specific gravity of the urine was 1.014-1.019; acid; no albumin; no sugar; occasional leukocyte. Temperature, February 25 to March 22, 97.6-99.2 F. Pulse, February 25 to March 3, 88-108; March 3 to 17, 88-120; March 17 to 22, 76-118. February 28, weight, 120 pounds.

Treatment and Result.—February 25 to March 1 the patient was given neutral quinin bromid gr. v, three times a day, with no apparent results. March 3 to 17, thyroidectin gr. v, t. i. d. The patient was not confined to bed during her stay in the hospital. March 3 the circumference of neck was 33 cm.; pulse, 80; marked exophthalmos; slight tremor; no marked nervousness. March 4 her weight was 121.5 pounds. March 15 the circumference of the neck was the same; patient felt less nervous; had less palpitation when recumbent; had had headache after 9:30 a. m. every day since beginning thyroidectin; the objective signs were unchanged. March 17 thyroidectin was discontinued; the patient had only one headache subsequently. The only improvement was a gain in weight to 127 pounds. March 28 the patient was transferred to the First Surgical Division and the right lobe and isthmus were removed.

CASE 2.—*History*.—M. B., a married woman aged 38, housewife, native of United States, entered New York Hospital, O. P. D., June 20, 1905. One child died of tuberculosis. The patient was accustomed to take one to two cups of tea, one of coffee, daily. For three years the patient had had a cough, with mucopurulent sputum in the morning, and during that time had lost 60 pounds. For two years the patient had had dyspnea on exertion. Patient was seen in 1904 on account of swelling of front of neck which she had just discovered, though her family had noticed it two or three years previously. At that time she had enlargement of the thyroid, exophthalmos, tremor, and, at left apex, prolonged expiration and subcrepitant râles; temperature, 99.2-99.6 F.; pulse 88-156. For two or three months the patient had had general pruritus, excepting of face; for five or six months pain in the lumbar region; had diarrhea with tenesmus for the previous three weeks; complained also of loss of weight and strength, palpitation and nervousness.

Physical Examination.—The patient was fairly well nourished; had decided exophthalmos. The conjunctivæ were congested and the tongue was slightly coated. There was marked tremor of tongue and fingers. Cardiac apex-beat in fifth intercostal space, 11.5 cm. to left of median line; dulness to third rib, and nearly to median line; faint systolic murmur at second left space; pulse regular, small, moderate tension. There was moderate general enlargement of thyroid, especially right lobe; the circumference of neck over thyroid was 34 cm.;

there were systolic and diastolic murmurs over the thyroid. The temperature was 98.4 F.; pulse, 196. The specific gravity of the urine was 1.015; acid; no albumin; no sugar; one granular cast. The patient's weight was 142¼ pounds.

Treatment and Result.—June 20 the patient was given castor oil and salol, and commenced thyroidectin, gr. v, after food. Six days later, the bowels were normal, palpitation much less; temperature 99.2 F.; pulse 132. Palpitation was less until July 2, when it suddenly recurred. Nervousness was less until same date; exophthalmos diminished; tremor about the same; weight had increased about 2.5 pounds; pulse 168. An ice-bag over the precordia relieved the palpitation. Nervousness diminished until the supply of thyroidectin gave out on July 21; it then increased, as did tremor and exophthalmos, perhaps on account of excitement due to the death of the patient's mother. The pruritus was worse for the previous month; lumbar pains for two or three weeks. July 26, thyroidectin was resumed. August 9, the exophthalmos was less but the nervousness and tremor increased; palpitation occurred frequently; there were thirst, profuse sweating on exertion and headache. The thyroid had enlarged; circumference of neck, 36 cm.; distinct systolic thrill and pulsation and loud double murmur over thyroid. August 21, palpitation was constant and severe; there had been pain in the epigastrium for the previous week, with diarrhea. The pruritus was less; headaches continued; thyroid the same; tremor increased; temperature 98.8 F.; pulse 176. The thyroidectin, which had caused no permanent improvement, was discontinued.

Case 3.—*History.*—L. W., female, aged 47, widow, laundress, native of United States, entered New York Hospital (Medical No. 12,406), April 27, 1905. One sister had enlarged neck but not prominent eyes. The patient had had measles twice; menstruated regularly. She had seven children, and had had no abortions. She was accustomed to drink about six cups of tea and three of coffee daily. About May, 1902, the patient's physician noticed that her neck was swollen; she complained of occasional cardiac palpitation. In May, 1903, she felt very nervous and had some puffiness of the ankles; was in New York Hospital, May 20 to June 27, 1903, with exophthalmic goiter and cardiac dilatation. While in bed both conditions improved markedly, and showed tendency to aggravation when she was allowed up. For one year after this the patient felt well, except for some palpitation and occasional diarrhea; had been growing weaker constantly for previous year; had been unable to work for previous three weeks. She had increasing dyspnea on exertion; she had had a cough during the winter; at time of examination it was less and with no expectoration. She had some frontal and vertical headache; no visual symptoms or edema; no increase of exophthalmos or size of neck; chief complaint, weakness.

Physical Examination.—The patient was fairly nourished, with flabby muscles. There was slight prominence of the eyes; Stellwag's sign was slight; von Graefe's sign absent. The tongue was very slightly tremulous. The thyroid was somewhat enlarged asymmetrically; there was no palpable pulsation, but fine systolic thrill and loud bruit over gland, much more marked on left side. The cardiac apex-beat was in fifth intercostal space, 10 cm. to left of median line; forcible; there was a systolic murmur at aortic area and at apex transmitted toward axilla; pulse full; considerable tension. The lungs were normal, except cog-wheel inspiration at apices posteriorly and slightly exaggerated breathing at left apex. There was marked tremor of the hands. The temperature was 99.6 F.; respiration, 28; pulse, 120; subsequently 80-100. The specific gravity of the urine was 1.016-1.023; acid; faint trace of albumin; no sugar; no casts. April 28, the patient's weight was 118 pounds; she was not confined to bed.

Treatment and Result.—Thyroidectin was given, gr. v, three times a day; emulsion of cod liver oil half an ounce after food. May 19, thyroidectin was discontinued. The pulse was 96-112; rate quite as high as before treatment. The patient's weight had increased to 123 pounds. Improvement was less than with rest in bed during previous stay in hospital.

Case 4.—*History.*—E. P., a married woman aged 45, housewife, native of United States; entered New York Hospital, O. P. D., March 30, 1907. The patient's father had rheumatism. The patient had had no diseases of childhood; she had had frequent "bilious attacks," and for five years, papular eczema every winter; and cough in the morning for years. She was accustomed to drink one cup of tea and one cup of coffee daily. About Dec. 22, 1906, after an unusually hard day's work, the patient became tired and thirsty and could not sleep; she then noticed inability to speak quickly and was easily fatigued. Early in January, 1907, the patient began to have dyspnea on exertion, palpitation after meals, bad taste, swelling of ankles. Toward the end of that month the patient noticed slight swelling of front of neck, varying slightly in size. Her weight was 135 pounds six months prior to admission; she became thin in January; was always puffy under the eyes, worse for the previous month. She vomited three times three days prior to admission.

Physical Examination.—The patient was rather poorly nourished. The eyes were slightly prominent, with puffiness of lower lids. There was slight general enlargement of thyroid, especially right lobe and isthmus; circumference of neck, 31.5 cm. The cardiac apex-beat was in sixth intercostal space, 12.5 cm. to left of median line; forcible; there was dulness to the second rib and to the left border of the sternum; systolic murmurs at second right and left intercostal spaces; the pulse was of fair size, moderate tension. Above the right clavicle and in first intercostal space were dulness, bronchial breathing, whispered pectoriloquy; above spine of right scapula, same. There was liver dulness from the fourth intercostal space to 4 cm. below costal margin in right parasternal line. There was very slight tremor of the fingers. The temperature was 99.2 F.; pulse 104. The patient's weight was 109.5 pounds.

Treatment and Result.—Rhubarb and soda with nux vomica were given before meals; thyroidectin gr. v, after food. April 6, there were no gastric symptoms; no dyspnea on exertion. The specific gravity of the urine was 1.026; acid; no albumin; microscopically negative. April 11, there was slight increase of exophthalmos and tremor, both of which had diminished one week later, while the weight had reached 115. By May 7, the patient had been taking thyroidectin irregularly for the previous week. She then had a choking feeling when hurrying; venous hum over jugular veins; aortic second sound accentuated; systolic murmur over precordia, maximum intensity in second right intercostal space; pulse occasionally irregular in frequency; hemoglobin, 64 per cent. (von Fleischl). She was now given iron, arsenic and strychnin in addition to thyroidectin. May 15, there had been palpitation for two days, which at times seemed slightly diminished by thyroidectin. The weight was 110.5 pounds. Along the left border of the sternum there was a scraping systolic murmur, maximum intensity in the third and fourth intercostal spaces, close to the ear, sometimes increased by bending forward; at other times when straight, after bending forward; there was a systolic murmur at the second right intercostal space. Thyroidectin was given, gr. x, after food for three days, then gr. v, after food. May 27, palpitation was worse while taking thyroidectin gr. x, after food; it was relieved by sodium bromid gr. x, taken as needed; recurred after taking thyroidectin gr. v, after food, again. June 4, there was increased tremor; the heart was overacting; the pericardial friction sound was still audible. The patient was given tincture of belladonna, Blaud's pills. June 17, the patient's weight was 108.5 pounds; hemoglobin 80 per cent.; circumference of neck same as on admission; little palpitation or dyspnea. July 17, the patient's weight was 105; temperature 98.7 F.; pulse, 84; there was increased exophthalmos; perhaps increased tremor; little palpitation. The patient was given thyroid extract gr. v, twice a day after July 24. Severe palpitation began on July 28, with edema of face and feet; the patient felt weak on rising. July 31, the patient's weight was 112.5; temperature 98.8 F.; pulse, 108, and very irregular in frequency; there was increased tremor. The patient was given thyroidectin gr. v, after food. After four doses she was much worse; palpitation, weakness and nervousness were present, and edema of legs more marked. The patient's weight was 116.5; temperature, 99.4 F.; pulse, 108, of slightly increased tension. There was increased exophthalmos. Thyroidectin was discontinued. The patient was treated subsequently with sodium bromid, belladonna, strophanthus, tonics and ice-cap over the heart. The patient's weight rose to 123 pounds. Symptoms of exophthalmic goiter varied as before. The heart showed signs of dilatation and hypertrophy, with marked irregularity in force and frequency of pulse; the urine was of low specific gravity; edema of whole of lower extremities was present, also gastric disturbance. July 1, 1909, the thyroid was smaller; there were no symptoms of exophthalmic goiter except slight exophthalmos; the symptoms were chiefly edema and diminished urine, of specific gravity not above 1.016; no albumin.

Case 5.—*History.*—The patient, M. W., a widow aged 36, domestic, native of Ireland, was seen May 15, 1908. Her father died of tuberculosis. The patient had had measles, variola, scarlatina and pertussis. She married in 1900; one year later had still-birth at term; then three abortions at two to three months; finally labor at eight months, three and a half years before the time of examination; the child was living. Menstruation had been irregular before the patient's marriage; after labor no menstruation for two years. Hemorrhage preceded all abortions and labor, and dyspnea and edema of legs were present in all pregnancies. The patient had had cough since marriage; sputum white; at times blood-streaked; for the previous four years cough only in winter. She was accustomed to take five cups of tea daily. At 12 years of age the patient had several frights; began to have choking feeling, then marked tremor; palpitation when excited; did not notice goiter until she was 15, though friends had observed thickness of neck for one or two years. At that time the patient had dyspnea, increasing weakness, and prominence of eyes. The symptoms were worst at the age of 17; six months later she was obliged to stop work, and was in hospital twice for three months. The patient was treated ten or twelve years with belladonna, digitalis, ergotin, quinin, iron, arsenic and bromids; improved at 24; was able to work later, but nervousness and tremor continued; she had been losing weight for years. From 12 to 26 years the patient had frequent stools soon after meals; no other symptoms. Beginning work in new place May 12, the patient became very nervous and had had repeated attacks of tachycardia, so severe as temporarily to prevent working.

Physical Examination.—The patient was poorly nourished and very nervous, with flushed face and slight bilateral exophthalmos. She had a marked tremor, especially of hands, so severe that she could not handle fluids without spilling them. There was general, soft, uniform enlargement of the thyroid, with overlying veins distended; the circumference of neck was 38 cm. The cardiac apex-beat was heaving, in the fifth intercostal space 9 cm. to the left of the median line; there was dulness to the third rib and to the median line; systolic murmur at apex transmitted slightly to left; from the second rib upward to and over the thyroid, there was blowing systolic murmur; loud venous hum over vessels of neck, especially during systole.

Treatment and Result.—Thyroidectin, gr. v, was given after food. May 17, the patient was less nervous; pulse, 96 to 100, regular; hemoglobin, 68 per cent. The patient was given ovoferrin after food. May 22, she had had epistaxis for one week at intervals; there was less tremor and nervousness; pulse, 96; circumference of neck, 37 cm. Thyroidectin was given, gr. x, after food, for four days, and patient thought improvement continued, but she was more nervous; pulse was 96 to 108; weight 91¾ pounds. Thyroidectin was discontinued; sodium bromid was given, gr. x, before food, and soon afterward, iron. July 12, the patient's weight was 99¾; hemoglobin 103 per cent.; there were no severe nervous attacks with tachycardia; otherwise the patient's condition was the same. After resting for two months patient returned to work, weighing 107 pounds, and attacks recurred. The left lobe of the thyroid, partially intrathoracic, was removed; four months later, the patient's weight was 115. The exophthalmos, nervousness and tremor gradually subsided. Jan. 17, 1910, there was still some nervousness, tremor and slight tachycardia when the patient was excited, but much less than before operation.

On account of the uniformly unfavorable results, thyroidectin was used in no further cases.

Before the introduction of thyroidectin, I had employed desiccated milk of the thyroidectomized cow and goat, each in one case. The histories are as follows:

Case 6.—*History.*—A. A., a married woman aged 38, housewife, native of United States; entered Vanderbilt clinic Feb. 4, 1905. The family and previous history were negative in their bearing on present illness. Menstruation was normal. The patient was accustomed to take two cups of coffee and four of tea daily. In February, 1903, the patient noticed a swelling in the right side of the neck anteriorly; two or three months later she began to have constant palpitation, loss of weight, nervousness and enlargement of the remainder of thyroid; swelling increased gradually but steadily. The patient did not menstruate in July, August and September, 1903, but was regular following that time. The patient improved at intervals under treatment, but was not kept in bed at any time. After any excitement the patient had diurnal headaches, chiefly frontal and vertical. The patient had not noticed prominence of the eye-balls until told of it by her physician in May, 1903. Protrusion diminished slightly after that time. Dyspnea had occurred on exertion for the past year. There were slight dry cough and hoarseness since December, 1904. Chief complaints: nervousness, palpitation, headaches.

Physical Examination.—The patient's face was flushed. There was slight exophthalmos; von Graefe's sign was present; quivering eyelids. The whole thyroid, especially the right lobe, was enlarged; the circumference of the neck was 38 cm. There was a double murmur over the thyroid, especially at the sides; a constant bruit and thrill over jugular veins; loud systolic murmur over carotid and subclavian arteries. The cardiac apex-beat was in the fifth intercostal space 10 cm. to left of median line, heaving; there was an area of dulness to the third rib and to the left border of the sternum; and a systolic murmur over whole precordia; first sound reduplicated at the apex. There was marked tremor of the hands; varicose veins and slight edema of legs. The temperature was 98.4 F.; respiration, 28; pulse, 132. The patient's weight was 142.5 pounds. The specific gravity of the urine was 1.011; acid; no albumin.

Treatment and Result.—February 4 the patient was given tincture of digitalis and a mixture containing bromids with nux vomica. During the ensuing week the patient felt much better in every way; pulse fell to 108; weight increased two pounds. Four days later the patient reported severe palpitation and no decrease of nervousness; temperature 98.8 F.; pulse 108. She was given desiccated milk of thyroidectomized cow, gr. v, three times a day. March 2, temperature 99.2 F.; pulse 132. March 6, the patient reported constant palpitation and weakness; she said that the goiter seemed swollen every night; temperature 98 F.; pulse, 184. There was no change in nervousness, tremor or exophthalmos; circumference of the neck was 39 cm. A letter from her husband, dated March 23, forcibly reported apparent results of treatment. "My wife since she commence to take those capsules her heart was about to jump out of her body and I put a stop to her taking them. She will not call again upon you."

Case 7.—*History.*—H. E., a married woman aged 42, housewife, Hungarian, entered Vanderbilt Clinic, March 11, 1905. The family and previous history were negative. The patient had one healthy child born twelve years previous to admission. A few weeks later the patient noticed a slight swelling in front of neck, which increased rapidly for one year; not subsequently. The patient was married a second time three years previous to admission; and after that had much domestic trouble and became very nervous. One and a half years prior to admission the patient began to have swelling of the right lobe of the thyroid, which increased gradually and was occasionally painful, especially at night. For the previous six or eight weeks, there had been rapid and exaggerated heart action; no exophthalmos or tremor. The patient would eat only at supper time on account of excitement, and drank six to eight cups of coffee daily.

Physical Examination.—There was no exophthalmos; cyst about 1¼ inches in diameter in isthmus of thyroid; right lobe similarly enlarged; no bruit over gland; circumference of the neck over the large cyst 38.5 cm. The cardiac apex-beat was in the fifth intercostal space, 11 cm. to left of median line; there was dulness to the third rib and to 0.5 cm. to left of left border of sternum; a faint systolic murmur at second right intercostal space. The pulse was regular. There was slight tremor of the hands. The temperature was 100 F.; respiration, 28; pulse, 96. Urine: specific gravity 1.018; acid; no albumin; microscopically negative.

Treatment and Results.—The patient was given extract of belladonna gr. ¼, every four hours, and a mixture containing bromids and nux vomica. The temperature was 98.8-99.6 F.; pulse, 92-120. April 1, there was no pain in the neck; otherwise the symptoms were the same; the circumference of the neck was 36.5 cm. April 4 there was increased palpitation and nervousness; the patient was given desiccated milk of thyroidectomized goats, gr. v, three times a day until May 18. Temperature was still 99-99.6 F.; pulse 96-112. April 20, there were less nervousness and palpitation. May 2, the patient felt much better; the cyst was less tense, but the circumference of the neck was unchanged. One week later the patient was still having palpitation but no nervousness, and had complained of pain in left side of the thyroid for two weeks. May 18, pulse 84. Desiccated milk was discontinued. May 23, there was no nervousness; less palpitation.

Summarizing the apparent results of treatment with thyroidectin without absolute rest in bed—apparent, because of the well-known variability of symptoms in exophthalmic goiter and the powerful effect on the nervous symptoms of suggestion of the potency of a new remedy—we find:

In Case 1, with treatment for two weeks with thyroidectin gr. v, three times a day, the nervousness diminished and tachycardia was less when the patient was recumbent; but there was no actual improvement save gain in weight. Headaches were present daily while the patient was taking thyroidectin; they ceased immediately when it was discontinued, except one day.

In Case 2, with the same dosage for nine weeks, with the exception of five days, the patient showed diminution of palpitation and nervousness at first. Subsequently all symptoms increased.

In Case 3, with the same dose for three weeks, there was slight general improvement, less than with rest in bed during the previous stay in the hospital; and no greater than change of habits and partial rest would account for.

In Case 4, the patient, treated fifty-seven days with gr. v, after food, and three days with gr. x, after food, showed very slight initial improvement, apparently a coincidence, or due to suggestion. The symptoms later became more marked under treatment; at times apparently exaggerated by thyroidectin, especially by dose of gr. x, after food.

In Case 5, treated seven days with gr. v, after food, and four days with gr. x, after food, the patient showed less nervousness and tremor during treatment. The symptoms were always greatly aggravated by any excitement. The patient was under great nervous strain when first seen. There was no real permanent improvement.

The patients had had symptoms for nine years, three years, three years, three months, and twenty-four years respectively, before thyroidectin was given. All the cases were of moderate or marked severity, except Case 3. Two showed severe cardiac lesions. Thyroidectin was given for from eleven to sixty-one days; dosage, gr. v to x, after food. Temporary improvement of symptoms was chiefly in tachycardia and tremor.

While none of these patients showed any real improvement excepting what would be amply accounted for by rest and regularity of habits, Patients 3, 4, and 5, if seen only during the early part of the treatment, might have been reported as improved. Their subsequent course suggests great caution in interpreting the reported 100 per cent. of improved cases.

The two patients treated with desiccated milk of thyroidectomized animals showed, in one instance, very marked aggravation of symptoms, especially tachycardia and weakness; in the other, nervousness disappeared, palpitation diminished, and the pulse-rate, previously 92-120, fell to 84-90. This case might have been considered improved, but regulation of excessive coffee drinking might largely account for this change.

My impression is that whatever improvement was noticed in any of these cases was due to rest, regulation of habits, and suggestion, or was a coincidence. The aggravation of symptoms may also have been a coincidence, but when it occurred it followed very closely the periods of administration of the drug.

SUMMARY

The few recorded results with thyroidectin in exophthalmic goiter are, on the one hand, improvement in 100 per cent. of thirty-six cases reported by three writers; on the other, one unfavorable report on twelve cases, one of negative results in a single case, and general condemnation, without details, by three observers. To these I add five cases, none of which gave results which were greater than the ordinary variation in symptoms in exophthalmic goiter under the influence of rest, suggestion, and regulation of habits, while in one case the remedy appeared to aggravate the symptoms. My two patients treated with desiccated milk of thyroidectomized animals showed extreme aggravation of symptoms in one case, apparently a direct result of the treatment, and in the other improvement, probably due to restriction of coffee. The results of treatment with thyroidectin seem far inferior to those secured by rest, symptomatic medical treatment, or partial thyroidectomy.

201 West Fifty-Fifth Street.

SUCCESSFUL REMOVAL OF BRAIN TUMORS

A CEREBELLAR TUMOR AND AN ENDOTHELIOMA OF THE PREFRONTAL DURA MATER

LEO NEWMARK, M.D.
WITH
H. B. A. Kugeler, M.D., and Harry M. Sherman, M.D.
SAN FRANCISCO

The fortunate outcome in these cases of cerebellar tumor and endothelioma of the dura is offset by an unhappy termination of our endeavors in a considerable number of instances of intracranial growths. There have been records enough of others' failures, however, to console us, and enough of successes to encourage us to persevere. The following account may render at least the latter service to those who need it.

Case 1 (By L. Newmark and H. B. A. Kugeler).—*Abstract.* Headache and vomiting began in November, 1908. In March, 1909, impairment of vision. In September, 1909, *exploratory* punctures and aspiration of (normal) substance from *both* cerebellar hemispheres. Escape of cerebrospinal fluid from puncture on the *right*. Subsidence of papillitis, and apparent good health for ten months. Then return of suffering; anesthesia in *right* trigeminal area. In November, 1910, *removal* of tumor from *left* cerebellar hemisphere.

Symptoms.—The patient was a girl 20 years old at the time of this report. In June, 1906, she is said to have vomited on three occasions, each time after supper, but without apparent cause. For six months thereafter the menses were suppressed. Otherwise she was quite well until November, 1908, when she began to have headaches and occasional vomiting on rising in the morning. At first the vomiting would occur about once a month, without relation to menstruation; after three or four months the intervals became shorter, until in the spring of 1909 they were reduced to two or three days. In March, 1909, her sight began to fail; she would be unable to read what she had produced on the typewriter. She held her head stiffly and inclined to the right, raising the right shoulder at the same time. We saw her together first on August 3, 1909, a few days after she had vomited so violently as to cause a severe gastric hemorrhage. The patient was cheerful and chatted volubly, and ordinarily did not give the impression of suffering. She said, however, that she always had more or less headache, "all over," but chiefly in the back of the head. We found papillitis in both eyes. Vision was considerably reduced in the right eye, but was quite good in the left. The eyeballs were both rather prominent. There was no nystagmus; nor was there any strabismus, although the patient mentioned frequently that she saw double, and once the diplopia continued all day. Dr. Adolph Rosenthal of the German Hospital, who examined her with us at the hospital, considered the diplopia to be due to incoordination of the ocular muscles. Inquiry elicited the statement that there was sometimes a numbness of the right half of the upper lip, but at this period we could not convince ourselves of any alteration of sensibility there (or anywhere else). The function of all the other cranial nerves was intact. When walking the patient now and then lurched very slightly to the left. During August, she would raise the right shoulder and incline the head slightly toward it on one day, and on another she might approximate the head and left shoulder. There was no incoordination of any kind in the upper or lower extremities. The tendon reflexes were all feeble at best; often the heel reflexes could not be elicited at all by any method; the knee-jerks were variable and required reinforcement, which would sometimes evoke both, and at other times only the left. The plantar reflexes were normal, the abdominal reflexes were absent on both sides. The pulse and the temperature were normal. The skull was not especially tender to pressure at any point, but the bone was perceived to be very thin and soft in the temporal regions, much more in the right than the left. X-ray plates seemed to confirm this impression; moreover, the sella turcica showed very faintly on them.

Deductions.—The papillitis, headache and vomiting were sufficient to prove the increase of intracranial pressure. The cause of this might be a tumor with or without hydrocephalus, or chronic hydrocephalus without a tumor. Lues was eliminated as far as possible. If a tumor was present the cerebellum seemed not unlikely to harbor it, for the manner of holding the head and the lurching, slight though it was, suggested that location, if they did not prove it. The fact that the headache was chiefly occipital seemed in some measure corroborative of this view. The absence of a disturbance of hearing excluded the cerebello-pontile angle from consideration; and the absence of nystagmus lessened the strength of our conviction that the tumor might be in the occipital fossa. On the one hand, there was a similarity to the symptoms of cerebellar disease; on the other, the absence of such frequent concomitants of cerebellar tumors as nystagmus and strabismus seemed to constitute a difference. This similarity with a difference induced us to regard a chronic hydrocephalus without tumor as not altogether improbable. The numbness of the right half of the upper lip, which the patient had mentioned only in response to an inquiry, could not weigh much in our balancing of the symptoms, because it was not present at this time.

Diagnosis.—As it was thought inadvisable to disregard the region where the atrophy of the bone was so conspicuous, a small incision was made, August 19, 1909, in front of the right ear. The bone was found to be as thin as paper. A slight slit was inadvertently made in the dura. Some of the subjacent brain substance was aspirated and examined under the microscope, and proved to be normal. A few days later 25 c.c. of cerebrospinal fluid were obtained from the right lateral ventricle through the same opening. It was reported to contain 0.2 per cent. of albumin and an excess of mononuclear leukocytes. We could not establish on this occasion that the ventricle was greatly dilated. On September 1 an incision was made on either side, midway between the external occipital protuberance and the apex of the mastoid process, and the bone opened with a small trephine. On the left side the same thinning of the occipital bone was found as in the right temporal region. On the right side the bone appeared normal. Substance was aspirated through each opening and submitted to Professor Ophüls, of Stanford University, who reported that "sections from both sides show cerebellum, no tumor." On the right side a hemorrhage occurred, so that the wound had to be packed with gauze. When two days later the gauze was loosened, there occurred a profuse flow of cerebrospinal fluid. The fluid continued to escape for ten days. The headaches, the vomiting and the pain in the eyeballs ceased and the patient was allowed to return to her home. When examined there a few weeks later the papillitis had disappeared, leaving the disks pale; the vision was 6/8 in the left eye and 6/10 in the right eye, as determined by Dr. Rosenthal. The patient took part in the work of the household and, although reported to be a trifle unsteady, with a little tendency to stagger now and then to the right, she was considered well until the end of July, 1910.

This subsidence of the symptoms after the discharge of cerebrospinal fluid had made us incline rather to the diagnosis of a chronic hydrocephalus without tumor. But the vomiting reappearing, occasionally at first with headaches, the patient was forced in August, 1910, to take to her bed again. She had to lie perfectly flat, as a pillow under her head would cause pain in the neck, occiput and eyes. At times there was tense bulging at the site of exploration in the right temporal and left occipital regions and well-marked fluctuation between the two on percussing the occipital area. September 23, 50 c.c. of cerebrospinal fluid were withdrawn from the right lateral ventricle through the temporal opening; vomiting and pain in the eyes immediately ensued and for three days there was a rise in temperature, the highest being 101 F. Occasionally some alleviation punctuated the patient's sufferings from vomiting and pain, so that she could be up and perform household duties. October 6 she was unconscious for fifteen minutes. November 23 we resumed our cooperation, one of us not having been able to see the patient for several months. The appearance of the disks, and the vision, had not changed during the year. Knee-jerks, ankle-jerks, and plantar reflexes were now all found to be perfectly normal. There was still neither nystagmus nor strabismus. The various tests for eliciting signs of disturbance of cerebellar coordination gave negative results. There was now a distinct diminution of tactile sensibility in the right half of the upper lip. This was said to vary: the patient said it was so marked at times that when she touched the right side of the upper lip with her finger and could not feel the lip she seemed to have lost her finger. This hypesthesia in the lip was most pronounced when the pain in the back of the head was most severe. The motor trigeminus was not affected. Deglutition was becoming difficult; the patient sometimes choked over her food. The pulse-rate was 120. There was no bulging through the opening in the skull at this examination. From November 25 to November 27 the patient could not swallow at all; a few drops of water were allowed to fall into her mouth from time to time. She was removed to the hospital, November 27 in the evening. The rate of the pulse was now between 130 and 140 and its beat was barely perceptible.

Further delay was evidently dangerous. It was therefore determined to examine the sites of the cerebellar punctures, one of which, by permitting the discharge of cerebrospinal fluid, had been so beneficial. It was hoped that this benefit might again be obtained by a repetition of the procedure and that the pressure on the medulla oblongata might be thereby relieved, thus permitting the patient to recover sufficiently to give an opportunity for a more extensive exploration of the cerebellum under less desperate conditions. The anesthesia in the distribution of the right trigeminus, as well as the consequence of the former intervention on that side, invited to operation on that side first.

Operation.—Accordingly, a few hours after the patient entered the hospital an incision was made through the scar. The dura was very tense. Puncture of the cerebellum produced, after two fruitless attempts, rather more than an ounce of a clear, amber-colored fluid, the first portion of which, spurting under considerable pressure, was lost. The intradural pressure was plainly lessened by the evacuation of this fluid. Further punctures yielding no more, an incision was made following the scar over the left cerebellar hemisphere, and there was disclosed a purplish mass protruding through a small opening in the dura. It was very soft and vascular, but after some effort a firm hold was secured and it was extracted entire through the enlarged opening in the dura and the bone. After its removal normal cerebellum was in sight; it soon pulsated freely. The patient was pulseless when returned to bed, but before long she recovered and in a few hours was able to swallow with ease. Nothing occurred to interfere with her restoration to health. The anesthesia in the right trigeminal area has disappeared. The patient is now (February, 1911) attending to her domestic duties, besides being active in her father's business.

The tumor measured approximately 5.5 by 2.5 by 2 cm. Professor Ophüls reported that it was a glioma of the cerebellum. The fluid which was obtained from the right cerebellar hemisphere contained but little sediment, which consisted or red blood-corpuscles, some granular and a little crystalline blood-pigment.

The salient points in this case are as follows:

1. The therapeutic effect of puncture of the cerebellar hemisphere opposite to that which contained the tumor.
2. The failure of puncture and aspiration at the site of the tumor to reveal its presence.
3. The non-recurrence of papillitis when the other symptoms returned.
4. The atrophy of the skull, probably the effect of pressure.
5. The anesthesia in the face, which might well delude one as to the side of the tumor. Ziehen mentioned in a discussion[1] as very remarkable "a *crossed trigeminus* paralysis" in a case in which he had diagnosed a cerebellopontile tumor, which, however, was not found at the operation, and Oppenheim stated in the same discussion that he also had once seen a contralateral trigeminal paralysis.

Case 2 (By L. Newmark; operation by Harry M. Sherman). —*Abstract.*—Intermittent headaches since 1906. Choked disks observed in November, 1907. Bilateral anosmia, pain in occiput and back of neck in March, 1908. In April, 1908, osteosarcoma on inner surface of trephine button removed from left prefrontal region. Permanent disappearance of headache and choked disks. December, 1910, removal of endothelioma of dura mater from same region.

It would seem in a sense to be an *extreme mischance* in localizing an intracranial tumor to discover it at last in the prefrontal region when it had been sought in the cerebellum. Yet such an error is not very uncommon, and in the course of the following notes it will appear how insistently at least subjective symptoms may direct one's attention to the back of the skull when the growth is situated in front. The tumor in our case was an endothelioma of the dura mater. Such a tumor is often a favorable object for surgery when it can be localized; but the diagnosis may be very difficult. Four cases observed by Nonne,[2] of Hamburg, illustrate this relation; in none of them was the tumor diagnosed, and in all it might have been removed with ease.

Symptoms.—The patient, a ruddy, robust Danish woman, aged 38, came under my observation at St. Mary's Hospital at the invitation of Dr. C. C. Mohun, March 23, 1908. Since "four weeks after the fire," that is, about May, 1906, she had been subject to paroxysms of headache, in the intervals between which she appeared to be well. The pain was formerly chiefly on the top, but of late commonly in the back of the head. Until the last attack of headache (which brought her to the hospital) the head would be drawn backward in the paroxysms and sometimes held retracted until the skin at the throat became sore from the stretching. The patient had had as many as three distinct attacks of headache in a single night, in which she would get on her knees and hold on to the upper part of the folding-bed, with her head drawn back. The head had remained thus retracted for a whole day at a time. In the attack, during which she entered St. Mary's, however, the head was inclined forward, so that the chin approached the chest, and in that position I found her, evidently in great pain, which, she said, she felt in the back of the head and neck, the back of the head being particularly painful on the left. The headaches often began with a "beating" in or behind the left ear. The patient had lost consciousness four or five times, not always, according to her husband, in a headache. There had been no convulsions. Ordinarily she did not vomit in the headaches, but during the last one she did, and, according to a witness, after the vomiting, a clear fluid "like water" came out of the nose drop by drop. Pain was felt often in the left eye, but not in the right. At times she would become blind for a moment. A few months before admission she could not see well after dark, so that after nightfall her husband had to lead her, but of late there had been an improvement in this respect. In November, 1907, Dr. James Franklin Smith had first observed choked disks.

Examination.—This disclosed bilateral anosmia. It was then elicited that the patient had observed the loss of the sense of smell several months before. Dr. Smith found no sign of a discharge of cerebrospinal fluid through the nose, such as the statement in the history suggested. The disks were both choked, the left a little more than the right. All the other cranial nerves were intact; all the reflexes and motor and sensory functions in the trunk and the extremities were normal. *A tremor in the upper and lower extremities was noticeable.* There was no exophthalmos, no strabismus, no real nystagmus, no cerebellar incoordination or staggering, no form of aphasia, nothing abnormal in the pulse or the temperature. Briefly, of the cranial nerves, only the first and second pairs supplied a clew; the functionally differentiated parts of the brain supplied none. The last assertion should perhaps be qualified; for the patient's husband declared that her character was changing. There was a sort of affected hilarity about her. I was furthermore struck by her indifference when I explained to her that an operation might be required to preserve her sight. The alleged change in her disposition and her inability to appreciate the gravity of her condition were taken into consideration later on weighing the arguments in favor of localizing the disease in the frontal lobe. Meanwhile, however, it was to the occiput that the patient's complaints drew our attention. By degrees, the severity of the paroxysm abating, the patient recovered from the prostrating headache with which she had entered the hospital, but still was cautious in moving her head until March 26. Then, although suffering no great discomfort in the daytime, she continued to have pain at night in the back of the head and neck, chiefly in the left half of the occiput. The pain was felt sometimes as far down as the upper dorsal region. The patient said that she could not lie on the left side on account of the tenderness in the back of the head on that side. The "beating" deep in the ear or behind it added to her distress; it was "like a clock." Tenderness to pressure was constant in the occiput on both sides, although it varied in degree on different days, and it was always greater on the left side than the right. Nowhere else in the skull was this tenderness found. The left frontal region was examined in this respect frequently and with special care. April 5, 1908, with the assistance of Dr. John Van Denburgh, the whole skull was percussed and auscultated, but no additional information was obtained. On the day before, the patient mentioned that she had had "little jerking movements of the head backward," and that she had felt them in the back of the head on the left side. April 5 I witnessed these movements, which were evidently due to short sharp clonic contractions of the muscles that retract the head. April 11 she vomited frequently, and it was

---

1. Neurol. Centralbl., 1907, p. 537.
2. Deutsch. Ztschr. f. Nervenheilk., xxxiii.

on April 13 that she felt the pain as far down as the upper dorsal region. She requested an operation, and April 15, when a hemorrhage appeared in the left disk, a sufficiently urgent reason was supplied to grant the request.

Diagnosis.—But where was the skull to be opened? The fundamental problem was the interpretation of the anosmia. This does not appear from the history to have been an early symptom, and it might have been caused by hydrocephalus, which in its turn might have been caused by a growth in the occipital fossa. Thus the combination of anosmia with tenderness and pain in the back of head and neck, and with spasms of the muscles that retract the head, would have been explained. The alternative was a direct pressure on the olfactory bulbs or nerves by a prefrontal tumor; but a single prefrontal tumor, unless it crossed the median line, would be expected to cause unilateral rather than total anosmia. There are abundant cases on record to show how fallacious tenderness of the occiput may be as a guide to diagnosis; yet the pain there, and the "beating" in the ear and the backward jerking of the head, were hard to disregard as indicative of the occipital position of the tumor. At length, however, the reflection that there was no impairment of the function of any organ lying within the occipital fossa determined the question in favor of the prefrontal region, in which judgment I was further confirmed by the reputed change in the woman's character. The subjective symptoms were allowed an influence on the decision as to which side of the skull concealed the tumor. The patient had finally called the left "the sick side:" the left disk was slightly more swollen than the right; so the left prefrontal region was chosen for the first exploration, despite the absence of aphasia in this right-handed person.

First Operation.—Accordingly, on April 16, 1908, Dr. T. E. Bailey trephined at a point about 4 cm. above the middle of the left supra-orbital ridge. The purpose was to probe the brain through the dura, and, if necessary, to aspirate particles of brain tissue for microscopic examination. From this point, furthermore, it would be feasible to tap the anterior horn of the lateral ventricle and to determine whether or not it was dilated. A puncture toward the base and median line was unproductive; a second, directed toward the occiput, encountered resistance at a distance of about 1⅛ inches; the instrument had entered something which seemed to be of the consistency of wood and a little force was required to disengage it. A week later a trephine was applied over the resistant substance, and when the disk was removed it was found that what the exploring instrument had encountered was a prominence on the inner surface of the bone, apparently an osteophyte, which had forced the subjacent dura rather deeply inward. The dura thus exposed was thickened. The opening in the skull was enlarged until normal dura was seen in all directions. The dura itself was not opened, as the removal of the projecting bone seemed sufficient to relieve the pressure on the brain. Dr. E. A. Victors was kind enough to prepare microscopic sections of the skull disk, and Professor Ophüls favored me later with the following report on the specimen:

Pathologic Report.—"Trephine button 22 mm. in diameter. Outer surface smooth, normal. On inner surface rough bony prominence forming a flat cone of 19 mm. base, projecting in the middle about 6 mm. On the rough surface there are small remnants of adhesions to the dura. The tumor evidently arises from the internal table and extends into the diploe for 3 to 4 mm. in an irregular fashion. The dividing line between tumor and diploe is rather indefinite. Section shows thick masses of lamellated, dense bone tissue with normal bone-cells. In the bony tissue there are large open spaces which, above toward the diploe, are filled with cellular bone-marrow, below in the tumor proper with a cellular tissue made up of large spindle-shaped cells with large vesicular nuclei and little intercellular tissue between them. Osteosarcoma of the skull."

Postoperative History.—A few days after the operation, having doubts as to the sufficiency of what had been done, I intimated to the patient that a second operation might be necessary, to which she replied that she felt very well and would assent to no such proposal. Indeed, she has never again suffered from the headaches and has no complaint about her eyesight. When she left the hospital just one month after the operation the swelling of the disks had become less by 3 diopters, and the beating in the left ear and the tenderness of the occiput had disappeared. Only the anosmia remained. In a few weeks more the swelling of the disks had completely disappeared; they were pale, but the patient was conscious of no defect in her vision. Through the opening in the skull, covered by the skin, a mass now protruded. The woman was very distrustful of her medical attendants, asserting that they wanted to experiment on her, and would not permit an examination of the protuberance on her forehead. No one could prevail on her to present herself again for inspection. The insensibility to the benefit she had received, and her perverseness toward those who offered to continue their efforts in her behalf, were declared by her husband to be foreign to her character. From the summer of 1908 until one day in June, 1910, when I journeyed to her home in the country to see her, she was lost to sight. On the day mentioned she was found to be in the enjoyment of good general health, but she complained that of late the swelling on the forehead had become tender. It seemed to be larger than it was two years before, occupied virtually the whole forehead, jutting over the eyebrow, and it pulsated like normal brain. At the edges of the opening in the skull the bone was tender when touched. The disks were still pale and clear. The sense of smell had not been regained. The patient's memory was stated by her husband, as well as herself, to have become very untrustworthy. The disfigurement by the swelling on the forehead was keenly felt; she was ashamed to go about and children ran from her in fright.

Cosmetic considerations, therefore, had their influence on the patient, and at length she entered the University of California Hospital, where, on Dec. 5, 1910, Dr. Harry M. Sherman removed a tumor which weighed 140 grams. This again was kindly examined by Dr. Ophüls, who reported as follows:

Pathologic Report.—Large nodular tumor about 8 cm. in diameter. The nodules on the surface are closely set, rather regular, from 3 to 5 mm. in diameter, large veins ramifying in the spaces between them. Sections show a thin superficial layer of ordinary fibrous tissue (probably the dura). The tumor consists of a thin framework of vascular fibrous tissue in which there are badly defined rounded spaces tightly packed with partly flat, partly fusiform cells, arranged more or less concentrically. No intercellular substance. These cells resemble those which were found in the medullary spaces of the piece of bone [i. e., the trephine button removed in 1908]. Alveolar sarcoma (endothelioma) of the dura mater.

As Nonne, in the article referred to above, calls the endothelioma of the dura mater benign, I questioned Professor Ophüls on the subject, and he replied: "These tumors are a sort of border-line affair of a very low degree of malignancy, if any. There are other types of sarcoma of the same class, such as the giant-celled sarcomata of the bones and others."

The defect in the patient's skull beginning 1 inch above the eyebrow, extends 3¼ inches backward from the eyebrow; laterally it extends from within half an inch of the median line to the level of the external canthus of the eye. The olfactory sense is not abolished; she can detect strong odors like that of lysol, but more delicate scents escape her. Her visual fields are about normal, according to Dr. Scott Franklin's tests, and her vision is a trifle less than 20/20 in each eye. Her memory is still considered by herself to be defective. Her conduct is certainly more amiable; but this may be due to the consciousness of an improvement in her appearance. Such was her condition on Feb. 7, 1911.

Dr. Sherman describes the surgical aspects of the foregoing case as follows:

Mrs. L. presented herself with a large tumor in the left frontal region. At its lower limit it lifted the eyebrow from the bone, at its upper it extended beneath the hair, and transversely it reached from the midline of the forehead outward as far as the external angular process of the frontal bone. Its general level was 2.5 to 3 cm. above the normal, and the skin covering it showed a broad stellate scar. The tumor pulsated, and it was not known whether it consisted of tumor tissue or was a cerebral hernia of the decompressive order. To determine this question, if it could be determined before operation, a lumbar puncture was done. Only 6 c.c. of fluid were taken, under about normal pressure, but its loss gave the patient a severe headache and nausea and vomiting. The tumor seemed to be softer, but it was difficult to be certain about the change. All unpleasant symptoms lasted only a day or so. The operation planned was to be primarily exploratory, and secondarily curative, if possible, and an effort was to be made to get an improved cosmetic condition. In the hospital, where I kept the patient for a few days for observation, the nurses reported her as being cross, peevish and sometimes sullen.

Second Operation.—I circumscribed the tumor by a curved incision above it and turned down the skin flap, and this was not easy, for the deeper layers of the skin and the tumor were adherent closely, and the skin turned back was so thin, being only skin, that I feared for its vitality in the healing. This exposed the tumor, seen and recognized to be tumor tissue, and found to be growing from the margins of the opening in the skull made by Dr. Bailey at the first operation. Therefore, I circumscribed the tumor by a cut-through the bone, really a slot started in a burr opening, and cut by a de Vilbiss forceps. This did not, however, cross below the tumor above the orbital margin, for there was no space, so here the tumor was separated from the bone and the latter trimmed down to sound tissue by rongeurs, making a skull opening 4 by 6 cm. The fingers then slipped in along the line of separation between the tumor and the dura mater, extradurally, to a depth surprising because it was unexpected. The tumor was easily drawn out; practically no hemorrhage followed; the cavity left would have readily contained a small fist. This cavity was lined below by the dura mater, which was pressed down into a huge hollow in the frontal lobe. Because of the size of the cavity I abandoned my plan of putting in a silver plate to represent the bone removed, and, because I could not believe it right to leave a vacant space in the cranium, nor yet to fill it with salt solution, I put in some gauze sponges, leading the strands of them out on the surface, and tacked the flap back in place with a few silkworm-gut sutures. The patient did well and the skin flap did not die. At a later time (eight or ten days) I reanesthetized the patient and removed the gauze tamponade and formally sutured the flap in place, draining the space underneath it by a single cigarette wick. Again I did not put in the silver plate, for I was not at all sure that it would not be necessary to remove more bone, and that is my feeling yet.

Following the last intervention there was normal healing and the patient left the hospital well, but with a depressed area, which pulsated, in the place of the tumor.

It was noted by the nurses in the ward that the preoperative surliness became a postoperative sunniness, and scowls and complaints changed to smiles and compliments—a complete dispositional reversal.

THE TREATMENT OF ACUTE GENERAL PERITONITIS

A. D. BEVAN, M.D.
CHICAGO

In a discussion on the great advances in the science of medicine, a friend, a professor of pathology, said: "Yes, great advances are being made in pathology and bacteriology and by laboratory research, but the clinicians are making little headway; they are in much the same position they were a generation ago. What have the clinicians done, which will compare with the discovery of antitoxin and the prevention and cure of diphtheria by its use?" I challenged the statement at once.

I said: "I congratulate the research workers on the splendid work they have done and are doing, but when you assume that the laboratory research men are the only ones who are adding to the science of medicine, you simply show that your knowledge of medical progress is limited to your own field and that you do not realize the splendid scientific work being done by your clinical colleagues. What have the clinicians done which will compare in value with the discovery of the antitoxin for diphtheria? I will tell you. They have learned how to recognize general peritonitis, and they have learned how to treat it, so that the mortality, which a generation ago approached 90 per cent. or more, is reversed and we are now able, under favorable conditions in patients operated on early, to save almost 90 per cent., a showing which is quite comparable to the splendid achievements of the antitoxin of diphtheria."

I have been an interested spectator, and, to a limited extent, participant in this wonderful change. I can recall almost from memory most of the important milestones in the progress of events.

Mikulicz in 1880, in operating for the first time on a perforating stomach ulcer, in a way led to the modern surgical treatment of general perforative peritonitis. The value of this work was not at once recognized; in the next decade little was done in the way of operative treatment in cases of general peritonitis. As late as 1894 von Bergmann's assistant, Schlange, in Berlin, in discussing the subject said: "I want especially to emphasize the statement that laparotomy as a treatment of general suppurative peritonitis should be rejected." Beginning with about 1894 a good deal of active work was done in the operative treatment of peritonitis. Stühler of Strasburg (Strasburg Klinik) in 1890 collected reports of seventy-eight cases of drainage of the peritoneum in cases of peritonitis with fifty recoveries and twenty-eight deaths. Körte[1] in 1892 reported nineteen patients operated on for suppurative peritonitis with six recoveries and thirteen deaths. Between 1892 and 1897 a considerable advance was made, so that in 1897 Körte in a second article, which really lays down the foundation of our modern operative treatment, was able to present reports of 133 cases with fifty-one recoveries and eighty-two deaths, collected from Lennander, Rotter, Jalaguier, McBurney, Abbe and Richardson.

I was fortunate enough to be present at the Congress of American Physicians and Surgeons in Washington in 1897 when Senn, Abbe, McCosh, Fowler and Welch in a symposium on peritonitis brought the subject down to that date. In 1900 A. Tietze[2] reported the work from the Mikulicz clinic. He presented some interesting facts.

Mikulicz collected from the literature from 1885 to 1893 reports of thirty-five cases of general peritonitis with thirty-four deaths and one recovery, a mortality of 97 per cent.; from 1894 to 1896, sixty-eight cases with thirty-two recoveries and thirty-six deaths, a mortality of 52.94 per cent. He collected altogether reports of 231 cases with eighty-six recoveries and 145 deaths, a 37 per cent. mortality.

In 1903 Joseph A. Blake[3] reported the treatment of diffuse peritonitis by early incision, with removal of the focus of suppuration and stopping any further leak, lavage of the peritoneum and closure of the peritoneal cavity without drainage.

In 1904 George and Russell Fowler[4] reported 100 operations for general peritonitis in the previous three years with sixty-seven recoveries and thirty-three deaths. They emphasized the importance of the now well-known

4. Fowler, G., and Fowler, R. W.: Medical News, May 28, 1904.

and widely adopted Fowler position in the after-treatment of these patients.

In 1905 Noetzel,[5] an assistant in Professor Rehn's clinic at Strasburg, published an article which brings the subject very close to its present stage of development. He advocates:

1. Careful and rapid operating.
2. Removal of the existing pus with irrigation.
3. The removal of the cause of the suppuration or closure of any existing leak.
4. Drainage.
5. Washing out of the stomach.
6. Rectal injections of normal salt solution.
7. Withholding of morphin when possible.

The treatment outlined by Noetzel, plus the Fowler position, gives us the modern treatment of peritonitis most generally adopted. About this same time Murphy formulated the method of treatment which is widely known by his name. To quote from LeConte,[6] the essentials of Murphy's technic may perhaps best be stated under six headings, viz:

1. The rapid elimination of the cause of the peritonitis.
2. Drainage by rubber tube of the lowest part of the pelvis.
3. Elimination of all time-consuming procedures at time of operation.
4. The Fowler position.
5. The absorption of large quantities of water by the rectum.
6. The prevention of peristaltic movements of the intestines by withholding of all food and liquids by mouth.

LeConte says: "While the procedures of Murphy do not present anything particularly new, he has assembled in his technic all of the good things to do, and has eliminated the unnecessary or harmful ones." There can be no doubt but that the enthusiastic advocacy of the scheme of treatment which Murphy has formulated, has accomplished a great deal of good.

To-day the discussion of the treatment of peritonitis might well be considered under four heads:

1. The saline cathartic treatment advocated by Tait, and especially by the gynecologists, which is really a treatment of value, not for peritonitis, but for one of the common results of peritonitis, i. e., paralytic ileus.
2. The rest and starvation treatment emphasized by Ochsner, which is of value, not in general peritonitis, but in local peritonitis to prevent its becoming general.
3. The operative treatment of Blake: rapid elimination of the cause of the suppuration, washing out of the peritoneal cavity with normal salt solution and closure without drainage, unless in the presence of gross lesions demanding it.
4. The operative treatment emphasized by Murphy: rapid removal of cause, drainage without washing out of the peritoneal cavity, and continuous irrigation by rectum with normal salt solution.

I hope to show that all of these methods have their value and that there is a fifth method, or *combination* of methods, the result of a better and simpler assembling of the various means at our command.

I. THE SALINE CATHARTIC TREATMENT FOR PERITONITIS

In what class of cases and under what circumstances is the saline cathartic treatment indicated? Patients die from peritonitis from three causes: 1. General sepsis with bacteremia. 2. From a sepsis due to absorption of toxins from the products of infection in the peritoneal cavity. 3. From absorption of toxins by the mucosa of the intestines from the decomposition which goes on in a paralyzed alimentary tract—intestinal toxemia.

In gynecologic work, in operations on the tubes and ovaries, Tait and other gynecologists found many cases in which, after the operation, the patient would become tympanitic, because of paralytic ileus, usually from a local pelvic peritonitis, often of not severe degree, and if let alone many of these patients died of paralytic ileus from absorption of the toxins developed within the paralyzed bowel. These men soon learned that if they could get the bowels to move, they would usually save their patients. This condition of paralytic ileus is a very common one, varying greatly in degree as to the severity of the symptoms from simple so-called gas pains to complete obstruction, and may complicate many lesions and operations involving the peritoneum. In the cases of paralytic ileus due to a local peritonitis, or a peritonitis of mild degree, like that associated often with a gonorrheal infection of the uterine appendages, the paralytic ileus with its accompanying danger of absorption of toxins from the bowel can often be controlled by saline cathartics, enemas and the use of agents such as strychnin to stimulate peristalsis. In these cases the saline cathartic treatment is often the most valuable treatment that can be employed. Not infrequently, too, in the postoperative care of general perforative peritonitis, as I shall attempt later to show, this cathartic treatment, to overcome paralytic ileus, may be indispensable. Of course, no one who understands the principles on which the treatment of peritonitis is based would for a moment consider the employment of the saline cathartic treatment in a case of perforative peritonitis before operation.

II. THE SO-CALLED REST AND STARVATION TREATMENT

This is the Ochsner method. This method has a rational scientific basis and is of great value in certain cases. It is, however, not properly understood, and is often improperly employed. What is the scientific basis for this method?

As Stokes and Sahli years ago pointed out, the inhibiting of peristalsis by the use of opium, the withholding of food and cathartics and the washing out of the stomach favor the localization and walling off of a suppurative focus in the abdomen, and there can be no doubt that a local peritonitis can often be kept a local process, and a general infection prevented, by this rest and starvation treatment.

The rest and starvation treatment is indicated: (1) in cases of acute abdominal lesions of uncertain diagnosis in which it is thought best to watch for a time their development; (2) in cases of local peritonitis in which for some reason operative interference is not indicated; (3) as I shall show, in the after-management of a case of peritonitis, in which operation has been done. It is, on the other hand, never indicated as the treatment of a patient with general perforative peritonitis.

III. THE OPERATIVE TREATMENT OF BLAKE

Blake has shown that in a large proportion of cases, if the perforation causing the peritonitis is properly closed, or the focus of infection causing the peritonitis is completely removed, and the noxious pus and toxins washed out of the peritoneal cavity with normal salt solution and the peritoneal cavity closed without drainage, the patient goes on to a recovery. This treatment shows the great power possessed by the peritoneum of protecting itself against pus infections.

---

[5] Noetzel: Beitr. z. klin. Chir. (Bruns'), 1905, xlvii, 241.
[6] Le Conte: Ann. Surg., 1906, xliii, 231.

Dr. Blake has kindly given me the following outline of his management of cases of general peritonitis:

> It is well to divide these cases into two classes for treatment: first, those in which the peritonitis is due to a dissemination of the infection from an infected organ, such as an appendicitis; and in the second group, those cases in which the peritonitis is due to a perforation or rupture of the alimentary canal.
>
> The first class can be further subdivided into two classes: one in which there has been no localization of the infection and the process is evenly disseminated throughout the abdomen. In this class, when the cause of the peritonitis, as the appendix, for instance, has been removed, there is little or no difference in the appearance of the various portions of the peritoneum. In these cases I consider it unwise to attempt to drain the entire abdominal cavity, and simply put a drain through the wound in order to avoid mural abscess formation. Also, unless the exudate is very thick, I do not wash.
>
> In the second group there has usually been pocketing and the formation of local abscesses lined more or less with necrotic fibrin. In these cases I wash out and drain the pockets. Inasmuch as the process has usually pocketed in the pelvis, the drains usually go to the bottom of the pelvis.
>
> In the second class, namely, cases of peritonitis due to perforations, I uniformly wash the abdomen out in order to remove the material extravasated from the alimentary canal. In these cases I employ the same rule for drainage as in the cases proceeding from infected organs, that is, drain when there is necrotic material remaining in the abdomen; otherwise, no drains.
>
> To resume: My treatment is practically the same as that I advocated in Chicago in 1908, with the exception that I do not wash quite as much. For instance, patients with only a seropurulent exudate are not washed at all; neither are they drained:
>
> My rules for employment of drains are as follows:
>
> 1. Never use drains unless there is dead material which will remain as a nucleus for continued infection.
> 2. When it is necessary to drain, use a large and competent drain. For this purpose I use a double rubber drainage tube, one limb of which is fenestrated, and through this limb a wick of gauze is passed for capillary drainage.
> 3. Drains, when used, should be left in until all necrotic material has escaped, when they can be rapidly removed.
>
> I have given up the use of cigarette drains, considering them inefficient and therefore useless. A short rule I sometimes use is, drain when you have to drain; otherwise don't drain at all.

IV. MURPHY METHOD

The Murphy scheme of management is the one most widely employed in this country at present. Murphy emphasizes the importance of tubular drainage; strongly condemns irrigation of the peritoneal cavity; insists on continuous irrigation with normal salt solution by rectum, and employs the extreme Fowler position, having the patient sit up in bed. The remarkable results which Murphy has obtained by his method certainly furnish a very strong argument and constitute certainly one of the reasons for its extensive adoption. I do not think that it is well to be guided entirely by statistics in a matter of this kind, however, and the results of his early work—twenty-nine cases of general peritonitis with but one death—is probably the accidental grouping of a large number of favorable cases which will probably not soon be repeated.

My own conclusion after studying this matter with a good deal of care is that these four methods—the saline cathartic method of Tait, the rest and starvation method of Ochsner, the Blake scheme and the Murphy scheme—all have definite elements of value and fields of usefulness. On the other hand, the value and importance of these methods have often been much exaggerated by their partisan advocates, and the real value of other schemes belittled to the disadvantage of their patients.

In the light of the evidence now before us, what should be our scheme of management of cases of general peritonitis?

DIAGNOSIS

Diagnosis must be made early, within the first few hours, certainly within the first twelve, if we are to hope for much from surgical interference. This diagnosis must be made early from a few data: pain, tenderness, muscular rigidity. We cannot afford to wait for a high leukocyte count, for a marked increase in temperature, for a tympanitic abdomen and the thready pulse and dusky face of dying peritonitis. This is true especially of perforative peritonitis from the alimentary canal. Take a case of typhoid fever with perforation. If the patient is to be saved, operation must be performed because he has pain, tenderness and a rigid belly. One must not wait for the tympany and thready pulse, which are really not signs of disease, but signs of death. This sort of procrastination reminds me of the medical men who bring me cases of carcinoma of the breast, which they have watched for months patiently to see the case develop glands in the axilla, a retracted nipple and evidence of cachexia, before making up their minds as to the diagnosis of malignancy.

SURGICAL MANAGEMENT

In discussing the modern surgical treatment of peritonitis and attempting to estimate its value, we must assume that we have made a moderately early diagnosis and that the surgical interference is undertaken within a reasonable period after the onset of the peritonitis. I have frequently been called to operate in neglected cases, in which the patient was blown up like a barrel, with pinched face, cold extremities and without a radial pulse. I believe in giving a patient with peritonitis the benefits of an operation, if there is the least possible chance; on the other hand, it is a mistake to operate on patients who are evidently *in extremis.* The most important function for us to perform, in the propaganda for better medical management of peritonitis, is to teach the importance of early diagnosis.

What shall be the scheme of surgical management? I should like to discuss this under several heads, viz: (1) anesthesia; (2) incision; (3) proper surgical disposal of the perforation or focus of infection; (4) testing the peritoneal cavity to determine whether the peritonitis is local or general; (5) when there is free pus or noxious material in the general cavity, its removal by irrigation with normal salt solution; (6) drainage; (7) surgical dressing; (8) after-treatment—the modified Fowler position; (9) intermittent salt solution per rectum; (10) washing out the stomach; (11) question of medication, morphin and strychnin; (12) water and food by stomach; (13) paralytic ileus and the saline cathartic treatment.

1. *Anesthesia.*—The normal anesthetic in these cases is drop-ether, properly given. In cases in which the patient is in very bad condition, nitrous oxid gas should be employed, unless there is a heart lesion, and then ether is safer.

2. *Incision.*—The first incision should be made over the suspected focus. As a muscle-splitting incision for an appendix case, or a median line incision above the umbilicus for a stomach or duodenal case.

3. *Perforation.*—The perforation or leak must be so handled as absolutely to prevent any further leakage. I would be very insistent on this point. I have too often seen cases in which the peritoneal cavity was simply opened and drained without closing the leak permanently, and in which the patient was almost certainly lost because the leak continued. The teaching that if it is difficult and time-consuming, the leak should not be sought for and closed, is bad teaching. I should say that it is so important for the safety of our patient to close every leak or perforation of the alimentary canal causing peritonitis—that a most thorough closure should be obtained even at the cost of some risk and time. It is only in extremely difficult cases, with patients in such bad condition that they will evidently stand nothing in the way of operative interference, except an incision and the introduction of a drain, that we should make an exception to the rule. In cases of peritonitis from suppurative foci, other than the alimentary canal, as the uterine appendages, it is desirable to remove the focus entire, if the condition of the patient permits; if the patient's condition is bad, we can trust to drainage alone with somewhat better chances than in the cases with alimentary canal perforations.

4. *Testing the Peritoneal Cavity to Determine Whether the Peritonitis is Local or General.*—This, to my mind, is one of the most important and interesting developments in the modern technic. As an illustration let me cite two cases of appendicitis.

CASE 1.—A young man of 20 was brought into the hospital with the diagnosis of appendicitis. He had been ill several days; from the history, a perforation had occurred a few hours before. I operated at once and found a perforated appendix with free pus about it. This was removed and the stump invaginated into the cecum. I then took a female glass catheter and tested the abdominal cavity. I placed my thumb over the open end, introduced the point into the cul-de-sac, removed my thumb for an instant and then replaced it and withdrew the catheter, employing it in much the same way that one does a glass pipette in picking up urine from a bottle. As I withdrew the catheter I found the lower 5 or 6 inches full of creamy pus. I then knew that I had a free general peritonitis to deal with and handled it accordingly.

CASE 2.—A boy of 10 gave much the same history. I operated on him in the same way, and when I tested his cul-de-sac found nothing in the catheter except a small amount of clear peritoneal fluid, and I therefore handled this case as one which was still limited to the region about the cecum although the pus was free in that part of the peritoneal cavity.

5. *Pus in the General Peritoneal Cavity.*—When there is free pus or other noxious material widely disseminated in the peritoneal cavity, I believe that it should be removed by irrigation. No one would doubt the advisability of washing beer and sauer-kraut and wiener-wurst out of the peritoneal cavity, in a case of perforating ulcer of the stomach; why should we not do the same for fecal pus or any pus?

When I have tested the peritoneal cavity with a glass catheter in the way I have described and found free pus, I then make a small buttonhole counter-opening in the median line just above the symphysis; through this a large glass tube is carried to the bottom of the cul-de-sac; then through the main incision, whether for appendix or stomach, another similar tube is carried to the seat of the perforation or focus, and this is attached by a rubber tube to an irrigator filled with normal salt solution at 112 F. and the peritoneal cavity is flushed out with several quarts of this irrigating fluid, until the fluid comes out perfectly clear. Practically no time is lost in this part of the operation as we are closing the main incision while the water is running.

6. *Drainage.*—Rubber tubes should never be used in these cases for drainage, at least unprotected rubber tubes. Cigarette drains are much to be preferred. A long cigarette drain made of a small rubber tube about as large as a No. 10 or 12 catheter, about which gauze and gutta-percha tissue is wrapped, until it is the diameter of a lead pencil or little finger, is carried through the small buttonhole in the median line to the bottom of the cul-de-sac. Similar drains are carried to the point of closure of the perforation or removal of the inflammatory focus and the rest of the main wound is closed.

6. *Dressing.*—The surgical dressing should be a copious, moist, not wet, dressing of hot boric solution. A moist dressing picks up the discharge better than a dry dressing. These dressings should be changed every six to twelve hours, as demanded by the amount of discharge—usually twelve hours is often enough—sometimes twenty-four.

8. *Position.*—The Fowler position is of much value for these patients, but unfortunately an exaggerated position has often been insisted on to the great discomfort and disadvantage of the patient. I am sure that we have obtained all the possible benefits of the position by allowing the patient to lie flat in bed and elevating the head of the bed from 18 to 20 inches on two chairs. In order to prevent the patient from sliding down in bed a bolster is placed below the buttocks and held fixed to the head of the bed by strips of roller bandage. I should like to emphasize the importance of this method of using the Fowler position. I have seen patients positively tortured by being compelled to sit up in bed because the attending surgeon has been led to believe that this position was indispensable to the modern method of treating peritonitis.

9. *Saline.*—I think that we are all agreed that furnishing these patients with a large amount of fluid by the bowel is one of the important factors in securing for us our improved results. This matter has, however, been greatly overdone. Continuous irrigation by complicated apparatus is often insisted on, much to the unnecessary discomfort of the patient. The presence of a tube constantly in the rectum is annoying. What we desire to accomplish is to furnish the patient a large amount of water so that the kidneys can act well and excrete the toxins, and so that the system will have enough fluids for the comfort of the patient. This can be done by interrupted rectal irrigation with much greater comfort to the patient and with all the benefits that can be obtained from the continuous irrigation. The continuous irrigation, if pushed, may be a positive danger, sometimes producing edema of the lungs and of the extremities. The rule is to give from 6 to 16 ounces of normal salt solution every two to four hours, to be retained, and a cleansing enema once or twice a day.

10. *Stomach Washing.*—If the patient vomits repeatedly, the stomach should be washed out. I do not believe, however, in making gastric lavage the rule. If the vomiting persists, the lavage should be repeated. Great care should be taken to prevent, if possible, the development of acute dilatation of the stomach, a condition very similar to paralytic ileus. If the patient does not vomit, or if the vomiting is slight and soon ceases, the patient should be given water by the mouth, at first in small amounts, and as the conditions improve this can be increased with a corresponding decrease in

the amount given per rectum. If at the end of twenty-four hours after the operation the general condition is good, milk and vichy in small amounts—an ounce each —every hour, can be begun.

11. *The Question of Medication.*—Morphin should as a rule be withheld; and still, in a large minority of cases, when the pain and restlessness are great, it is often of great benefit, giving the patient sleep, better respiratory action and increasing his chances of recovery.

12. *Ileus.*—Paralytic ileus is sometimes a serious or even fatal complication. It is here that proper early use of saline cathartics has been of value. Most patients have more or less gas pains. These should be handled by stimulating injections given low in the rectum; I usually use magnesium sulphate and glycerin and water in equal parts. Where the distention is considerable and persistent, saline cathartics in small repeated doses, with stimulating enemas and strychnin in moderate doses, should be employed. In a few cases secondary operations for localized abscesses will be necessary, and in a few cases in which the ileus persists enterotomy will be required.

I have found that one of the most valuable means of combating paralytic ileus is castor oil in small and repeated doses. I usually give a teaspoonful every hour until peristalsis, with expulsion of gas and fecés, is secured.

I believe that following out this general scheme, we can, in cases early diagnosed and early operated on, succeed in saving a very large percentage of our cases of general peritonitis. And when our laboratory colleagues ask us what clinical surgery has done, we can tell them that for one thing it has solved the problem of peritonitis; that under favorable conditions it can save 90 per cent. of these patients who but a few years ago were almost certainly doomed to die.

150 Michigan Avenue.

RECONSTRUCTIVE ENDO-ANEURYSMORRHAPHY: A CASE REPORT

GEORGE S. CRABTREE, M.D.
Captain Medical Corps, U. S. Army
CULEBRA, CANAL ZONE

History.—O. K., a prisoner in the Zone penitentiary at Culebra, Canal Zone, a Jamaican negro, aged 27, presented a history of syphilis from 1903, the only evidences of which to be noted at the time of examination were a moderate general lymphadenitis and slight arteriosclerosis. This man received a gunshot wound of the right leg on the night of Dec. 31, 1909, while attempting burglary. The missile, a 38-caliber revolver ball, entering 2½ inches above, and on a plane ½ inch posterior to, the upper extremity of the fibula, in the erect position, direction inward, and slightly forward and downward, becoming imbedded in the internal condyle of the femur. The patient was admitted Jan. 1, 1910, to Culebra Hospital. The wound healed without suppuration and the patient was discharged from hospital Jan. 25, 1910. He worked in the chain-gang building roads until Aug. 13, 1910, when he was readmitted to the hospital. He stated that during April he noticed a slight swelling in the popliteal space, which very gradually increased in size, and that later he began to have some pain back of his knee, which came on at intervals; that these attacks of pain later increased in frequency and severity until on admission the pain was constant. There was also, at this time, considerable swelling of the leg, due to pressure of the tumor on the popliteal veins. Examination showed an expansile tumor, a bruit and all the classical signs of aneurysm. The patient was put to bed with the knee slightly flexed and elevated, and was kept there until September 15. The rest and posture relieved the pain and swelling of the leg somewhat, but the aneurysm increased perceptibly in size during the month he was at rest.

Operation.—Sept. 15, 1910: A tourniquet on the thigh made the operation practically bloodless. When the aneurysm was opened much lamellated fibrin was found; this was removed and the sac washed out and found to be about 4 by 2¾ by 2 inches in size. The arterial openings, i. e., the point of entrance of the popliteal artery into the sac and its point of exit from the sac, were about an inch and a quarter apart. As regards classification, the aneurysm should probably be considered as of the spherical type, from its evident mode of origin and from its shape. At the same time it partook of the character of a fusiform aneurysm, in that the arterial openings were an inch and a quarter apart, and that there was no groove or furrow between these openings to mark definitely the anterior wall of the artery. The character of the sac walls differed very much in different areas. The anterior wall of the sac, between the arterial openings and for some distance on all sides of this point, seemed firm, elastic and resistant, while from this area it gradually thinned out until the posterior wall of the sac was as thin as tissue-paper. A point of particular interest in this case was the presence of a second sac or diverticulum opening off the main sac cavity on its anterior surface at a point ¼ inch below the proximal arterial opening and on a line between the two arterial openings. Or, it might be said that this second sac opened off the anterior wall of the artery, except for the fact that the artery was so flattened out and obliterated that it seems simpler to call it the anterior wall of the sac. This diverticulum was an aneurysm of true spherical type, about ¾ inch in diameter, its opening into the large sac being about ⅓ inch across. It contained no clot or fibrin and its walls seemed firm and elastic, and lined with arterial intima over its whole extent. It was wiped out firmly with a pledget of gauze with the idea of encouraging the deposition of fibrin within the sac, and in the subsequent proceedings its presence was disregarded. The two arterial openings were on the same level, were easily accessible at the bottom of the field of operation, and, in the belief that there was enough firm sac wall available, the artery was reconstructed. For this purpose interrupted sutures of fine chromic gut were used, placed about 3/16 inch apart, using very fine, full-curved round intestinal needles. After reconstruction of the artery the sac was obliterated by layer on layer of continuous plain catgut sutures, following Matas' second method of closure, leaving the sac buried in the wound without inversion of the skin-flaps, and without drainage. After the second row of continuous sutures was in place the tourniquet was removed. Slight oozing of bright red blood showed immediately in the suture line, but it soon stopped and the operation was completed and the leg dressed on a straight posterior splint. There was immediate restoration of circulation to the leg, pulsation being felt in the posterior tibial and dorsalis pedis arteries.

Postoperative History.—From the time of the operation on there was never any difference in temperature or sensation between the foot and leg of the operated side and that of the sound side. The skin sutures of silkworm gut were removed on the twelfth day. The patient was kept in bed with leg on a posterior splint for three weeks, when he was allowed up, with a posterior molded felt splint in place for another week to prevent his flexing the leg. He was discharged from hospital October 16 and returned to work in the road-building gang at once. The man was seen repeatedly after he left the hospital by me, the last time on Feb. 19, 1911, and he stated that the leg had given him no trouble, and he had worked every day since he left the hospital.

October 14, two days before the man went out of hospital, and twenty-nine days after the operation, his leg was examined carefully in regard to its circulation, and it was found that the pulsation could be felt as readily in both the posterior tibial and the dorsalis pedis in the right (operated) leg, as in the left; at least, if there was any difference in the strength of impulse in the two sides it could not be made out by palpation. (We did not test the blood-pressure otherwise.) No impulse could be felt in the reconstructed portion of the popliteal, owing to scar tissue.

Professor Matas[1] brings up the question as to the continued competence of the reconstructed portion of the artery, and in order to decide the point, if possible, the man was reexamined again Feb. 19, 1911. He was very muscular and quite fleshy. Impulse in the popliteal at the seat of operation could not be made out. The posterior tibial and dorsalis pedis could be made out only with considerable difficulty on the right side, while they were distinctly palpable on the left, the impulse even being visible in the left dorsalis pedis.

Now to determine whether the stream causing the faint impulse really came through the reconstructed artery, an assistant made digital pressure over it while the branches were palpated and it was found that as long as the pressure over the popliteal continued there was no impulse in the branches, but that pulsation immediately returned when the pressure was discontinued, proving that the lumen of the reconstructed artery, while it has become considerably narrowed, still carries part of the blood-supply to the foot and leg.

This observation would seem to bear out the contention that in these cases of reconstruction in which there is permanent recovery, the reconstructed portion of the artery becomes obliterated ultimately, remaining patulous long enough, however, to carry on the circulation until the collaterals develop.

Regarding the second aneurysmal sac, which was left as a spherical aneurysm on the anterior wall of the reconstructed portion of the popliteal, I had serious misgivings at the time as to the wisdom of the treatment of it, and that was the reason for keeping the parts at rest for so long after the operation. However, its walls seemed to be about as firm as the material from which the artery was reconstructed and it impinged on the solid structures at the back of the knee, giving it support, and there were hopes that it might be obliterated, which, in the light of the last examination, seems to have been its fate.

The above is offered for what it is worth as an argument in favor of the reconstructive operation. The conditions presenting in this case certainly cannot be considered to have been ideal for this operation, yet the results have been all one could wish.

A SIMPLIFIED METHOD OF STAINING BACTERIA, CAPSULATED BACTERIA IN BODY FLUIDS, AND PREPARATIONS FOR OPSONIC COUNTS

LEON S. MEDALIA, M.D.
Pathologist and Visiting Physician for Vaccine Therapy, Mount Sinai Hospital
BOSTON

For over four years I have used with great satisfaction the following method for the staining of bacteria and body fluids in place of Löffler's methylen-blue, in the staining of preparations for the opsonic count instead of Leishman's or Wright's blood-stain, and in the staining of capsulated bacteria. I describe it here in the belief that it may be of help to clinicians as well as to laboratory workers.

PREPARATION OF STAINING SOLUTIONS

The preparation of this stain requires no saturated alcoholic solutions, nor the troublesome "1 to 10,000" aqueous solution of caustic potash necessary in the preparation of Löffler's methylen-blue solution. It is easily prepared in a few minutes by any physician or druggist and keeps indefinitely. The addition of a few crystals of sodium carbonate may be necessary from time to time to counteract the acidity of the corrosive sublimate which is used as a fixative.

1. Saturated aqueous solution of corrosive sublimate (to be used as a fixative).
2. Aqueous methylen-blue solution prepared as follows:

℞.	gm. or c.c.
Methylen-blue ("medicinally pure")	1
Sodium carbonate, U. S. P., cryst.	1
Water	100

The dye and the sodium carbonate are thoroughly dissolved in the 100 c.c. of water by shaking. If not thoroughly dissolved there may be a precipitate on staining.

These solutions are best kept in bottles wide-mouthed enough to allow the passage of slides or cover-glasses and stoppered with corks or glass stoppers.

METHOD OF STAINING

Staining of Single Preparations.—The smear is made on a slide or cover-glass and allowed to dry in the air:

1. Fix (by immersing the preparation in the saturated corrosive sublimate solution for from ten to twenty seconds).
2. Wash in running water.
3. Stain with the methylen-blue solution described above, by immersing the smear in the staining solution for from five to thirty seconds.
4. Wash thoroughly in running water and dry between layers of filter-paper; mount and examine in the ordinary way.

Staining of Several Preparations at One Time.—In the laboratory where it is necessary to stain many preparations the following method is recommended:

The smears are made on slides, are labeled with a blue glass pencil (A. W. Faber) and dropped in a glass slide box.

1. Fix by pouring the saturated corrosive sublimate over the slides, filling the glass slide box with it, and allowing it to act for from ten to twenty seconds.
2. Pour off the corrosive sublimate (back into the bottle).
3. Wash thoroughly in running water, holding the slides in the box by placing the fingers over the top of the box.
4. Stain with the methylen-blue solution[1] (described above) for from five to thirty seconds, by pouring the solution over the slides, filling the slide box with it.
5. Pour off the methylen-blue solution (back into the bottle).
6. Wash thoroughly in running water.
7. Dry between layers of filter-paper, and examine in the ordinary way.

Staining of Preparation for the Opsonic Count of Bacteria Other Than Tubercle Bacilli.—The method just described for staining several preparations at one time I have used since August, 1906, in staining preparations for the opsonic count of bacteria, other than tubercle bacilli, in place of Leishman's or Wright's blood-stain. It has given great satisfaction from the standpoint of results, economy, and saving of time. The great number of slides I had to stain daily for the opsonic count formerly meant the spending of hours in staining alone, while with this method it is now a question of minutes. A large amount of staining fluid is consumed when the "blood-stain" is used, because when once applied it cannot be used over again, while this methylen-blue solution can be used over and over again indefinitely; the economy is obvious. As to results, the staining of leukocytic granules (basophilic) with any of the standard blood-stains interferes with the rapid counting of the bacteria, while with this stain the protoplasm is pale blue, granules are not stained at all, and the bacteria and nuclei are stained deep blue. Hence the counting is rapid and without errors. This method, then, gives brilliant results, is economical, and saves a great deal of time.

---

[1] Private communication in reference to the case reported.

[1] In the staining of capsulated bacteria constant good results are obtained when the preparations are overstained, that is, allowed to remain in the stain for from five to ten minutes instead of from five to thirty seconds, and are not so thoroughly washed in water.

Method of Staining Capsulated Bacteria.—Thin preparations are made from body fluids (saliva, pus, exudates, etc.), are fixed, and stained by either of the two methods described, for single preparations or for staining several preparations.[1] The capsules show up invariably very distinctly. They are stained pale blue, while the bacteria are stained deep blue. Good results have been obtained, not only in smears from body fluids, but also in smears made from cultures (especially from the water of condensation) of the *Bacillus mucosus capsulatus*, the *Streptococcus mucosus capsulatus* and the pneumococcus. The advantages of this method of staining capsulated bacteria as compared with any other method I know of are obvious and need no further comment.

GENERAL APPLICATION AND RESULTS

This stain can be used in every case in which Löffler's methylen-blue would be used. It has all the advantages of the latter minus the disadvantage due to heat fixation. Thus, in smears of pus or body fluids, the protoplasm of the individual pus cell is stained light blue and its outline is definitely made out. Intracellular organisms (gonococci, meningococci, etc.) are seen within the protoplasm and not in a blank space around the nuclei of the pus cell, as is the case with Löffler's stain.

Its use in the staining of blood-smears for the opsonic or phagocytic count has given me more satisfactory results, is more economical, and takes considerably less time than any other stain(or blood-stain) recommended for this purpose.

Its use as a stain for capsulated bacteria, the ease with which it can be applied generally, and the more constant results obtained with it, will make this stain, it is hoped, a useful addendum to the present standard laboratory stains.

Finally, because of the ease with which this staining solution is prepared, the cleanliness with which it can be handled, and its advantage of requiring no Bunsen burner or flame of any sort, it is hoped that this method of staining will be of help to the clinical man in keeping up bacteriologic examinations in his office in the routine of his daily practice, without having to resort to a fully equipped laboratory for that purpose.

REPORT OF A CASE OF STERILITY IN THE AGED CURED BY THE USE OF THE WYLIE DRAIN*

CHARLES C. NORRIS, M.D.
Instructor in Gynecology, University of Pennsylvania; Attending Physician to the Maternity Hospital
PHILADELPHIA

History.—Mrs. J. S., aged 50, white, negative family history, had the usual diseases of childhood. With the exception of typhoid fever, eighteen years ago, she has never had a serious illness. The onset of menstruation occurred at 13. For the first six or nine months the flow was somewhat irregular and scant. After the first year it has been regular, about every twenty-eight days, although variations of three or even five days are not unusual. Bleeding usually lasted for four days, the last twenty-four hours being rather scant; the amount is about normal, the patient requiring seven or eight napkins daily for the first three days. Menstruation is of the same character now as it was ten years ago; there are no symptoms of the menopause. The patient usually has a slight feeling of weight and discomfort in the lower abdomen for the first day of the period; she has never had severe dysmenorrhea. Leukorrhea has never been profuse or pathologic. The patient usually has a slight, whitish discharge for a few days following the cessation of menstruation. The patient was first married when she was 22. When she was 31, her husband died of pneumonia; until a few months prior to his death, he was a strong healthy man. Five years later, or when the patient was 36, she married a second time. She has never been pregnant although she has always desired children, and has never adopted any means to prevent conception. Her chief complaint is of sterility. The patient has no subjective symptoms, and, in fact, first visited me to inquire concerning her sister on whom an operation for laceration of the cervix and perineum had been performed; at this time she lamented the fact that she was sterile. On inquiry it was learned that during the life of her first husband, a dilatation and curettage had been performed with the hope that this might result in widening the cervical canal so that pregnancy could take place. Dilatation without curettage was performed four years after her second marriage.

Examination.—The patient is a rather large, plethoric woman weighing 150 pounds. She is distinctly well preserved and gives the impression of being at least five years younger than she is. The bowels are regular; the heart and lungs are normal; the urine is negative. She occasionally has slight occipital headaches, not infrequently just before the menstrual periods; these, however, are never severe. Abdominal examination was negative. Pelvic examination showed that the outlet was nulliparous; the vagina was rather deep, and the anterior and posterior walls were in apposition. The cervix was normal in its transverse diameter, but was longer than usual and extended for at least one and one-half inches into the vagina. The external os was small although far from being of the pinpoint variety so frequently seen in young women. No evidence of infection was present in any part of the genital tract. The cervix pointed at right angles to the axis of the vagina. The uterus was normal in size, shape and consistency; it was in anteposition and movable. The ovary on the left side could be felt as an almond-shaped body, if anything rather larger than normal. It was movable and slipped easily between the fingers. The ovary on the right side was not palpated. No induration or other evidence of intraperitoneal inflammation was present.

Prognosis.—Taking into consideration, the fact that the patient had already had two dilatations performed for sterility, both at a period of life when conception was more likely to result than at her present age, a very guarded prognosis was given regarding the probability of pregnancy ever taking place. There was no history pointing toward sterility in the husband. After the couple had consulted for a few days they decided to have an operation performed.

Operation.—This was performed ten days before an expected menstrual period under ether anesthesia. The examination at this time confirmed the previous negative pathologic findings of the former examination. The right ovary could now be easily felt and was *normal*. After the ordinary antiseptic precaution, the cervix was widely dilated and kept on stretch for ten minutes. The uterine cavity was then explored; no curettage was performed. A rather thick Wylie drain[1] was inserted and the vagina lightly packed with gauze to keep the drain in position.

---

*Read before the Philadelphia Obstetrical Society, Feb. 2, 1911.

Postoperative History.—The vaginal gauze was removed in twelve hours. The menstrual period which was due ten days after the operation was delayed for five days; the patient was kept in bed until this had passed. The Wylie drain was allowed to remain in place for four weeks, during which time the patient was kept under observation. The next menstrual period, which was expected a little less than a week after the removal of the Wylie drain, never appeared, and a month or six weeks later, a positive diagnosis of pregnancy was possible. Pregnancy and labor were normal, the child's position being L. O. A. Labor lasted about sixteen hours, pains being severe during the last five hours. The perineum was torn in the median line for a depth of about 0.5 to 0.75 inch; this was repaired. The child weighed eight pounds. The puerperium was normal. Mother and child have done well.

The interesting points of this case seem to be the advanced age of the patient. It should, however, be borne in mind that she was a strong, healthy, well-preserved woman and that no symptoms of the menopause had appeared. Regular menstruation is not unusual until forty-eight or fifty as I have shown in a previous paper[2] in an analysis of 200 normal cases. In this study it was found that the average age at which the menopause appeared in this country was between 48 and 49, and that 21 per cent. of women menstruate until 50. Since the joint report of Dr. Barnard and myself[3] before the Philadelphia Obstetrical Society early in 1910, of a series of fourteen previously sterile women, in which five, or 35.71 per cent., became pregnant within one year following operation, I have had two additional cases, both occurring in women who had been married for two years and both of whom were desirous of children. In one, the patient became pregnant two months after the insertion of the Wylie drain. The second case was unsuccessful. A number of additional successful cases have occurred in the gynecologic department of the University Hospital. I would like again to emphasize the fact that the Wylie drain should never be inserted except under strict aseptic precautions, the same antiseptic and aseptic preparations being adopted for its use as for a vaginal hysterectomy or other major operations. Neither should the drain be used unless inflammatory lesions of the genital tract can be absolutely excluded. Patients in whom this form of treatment is adopted should remain in bed for ten days following the operation, and should be kept under close observation during the entire period that the drain is in place. No bad results have ever followed the use of the Wylie drain in my hands. In cases of sterility it is best to operate about ten days or two weeks before an expected menstrual period. In at least two cases which have come under my observation, conception has taken place while the drain has been *in situ*.

Just why pregnancy, after the age of 44 or 45 should be so rare as it is, is a little difficult to explain on purely anatomic grounds. Conception in the normal individual is always possible so long as ovulation persists. We have no means at our command of ascertaining exactly when ovulation ceases in any given case; however, we know that in the majority of cases ovulation and menstruation are synchronous.[4] And on this basis it would seem fair to assume that pregnancy would not be unusual so long as the latter function was in evidence. Despite this, it is a clinical fact that pregnancy, after 45 is rare and after 50 is exceedingly uncommon. Numerous cases, however, have been reported; indeed, instances have been recorded in which pregnancy has occurred some time after the entire cessation of menstruation. Buckle[5] reports a case occurring in a multipara of 50 years of age after cessation of menstruation for eleven years. Before subjecting a woman to any form of operative treatment for sterility, the husband should invariably be examined for aspermatism.

1503 Locust Street.

SYPHILITIC HYPERTROPHY OF THE INFERIOR TURBINATES WITH REPORT OF A CASE *

J. W. JERVEY, M.D.
GREENVILLE, S. C.

"It is difficult to mistake secondary syphilis of the nose for any other disease when a careful history is taken and a thorough examination is made." That is a "bromid" from one of our recent American text-books. It is unscientific, unpractical and, withal, untrue, for the anamnesis of the syphilitic is notoriously a history of guile, and the thorough clinical (which is evidently to be understood in the above passage) examination is often the ideal rather than the reality, for reasons with which the practical man is quite conversant.

Moreover, if it were difficult to mistake secondary syphilis of the nose for any other disease, it obviously follows that it would likewise be difficult to mistake any other disease of the nose for secondary syphilis, and the fallacy of such an attitude must at once be apparent. Even a negative bacteriologic examination would not be conclusively diagnostic, as everyone is aware, and while a positive finding of the spirochete would be more or less binding, yet, even here, the diagnosis is not infallible.

As a matter of fact, syphilitic lesions of the nasal mucosa are comparatively rare, which may or may not account for the scant attention the subject receives in most of the text-books. Yet, it is a matter of very great importance to the victim. In a practice of thirteen years I do not think I have seen (perhaps I should say recognized) more than half a dozen cases of undoubted secondary luetic rhinitis.

I believe we may safely say that there is no really typical appearance of intranasal secondary syphilis. Hence, a diagnosis, *ab inspectione*, we might aptly characterize as a diagnosis *sine circumspectione*. Even syphilitic ulceration of the septum, with perforation, does not carry with it any certainty of clinical diagnosis, for ulceration and perforation of the septum depending on some utterly different etiology may yet present an appearance which, on mere inspection, is wholly impossible of differentiation. In other words, while the secondary ulcer on the mucous membrane of the pharynx and fauces is usually quite characteristic (the familiar mucous patch), my limited experience teaches me that the ulcer occurring most often on the nasal mucosa is far less typical, being of the superficial variety. The fact may be, and probably is, due to the physically and physiologically more resistant tissues in the nares, together with possibly a thinner mucosa proper.

---

[1] The Wylie drain is a form of stem pessary, made from hard rubber, and is about 5.5 cm. in length. Along the edge of the stem is a groove. The base of the pessary is about 1.5 cm. in diameter. The diameters of the stems vary from 4 to 8 mm.

[5] Childbirth After Apparent Menopause, The Journal A. M. A., Aug. 13, 1910, p. 568.

* Read in the Southern Section of the American Laryngological, Rhinological and Otological Society at Lynchburg, Va., Jan. 22, 1911.

It is my belief, then—and at least I shall confess it to be true so far as my own present powers of diagnosis are concerned—that, excepting the primary chancre, the only cases of nasal syphilis that are usually promptly recognized on clinical examination are those that are first seen in the tertiary stages, when gummatous and necrotic processes are in extensive evidence.

Hypertrophy of the turbinates is a secondary manifestation of lues. The condition locally presents neither more nor less of the symptomatology of hypertrophy due to other causes, such as acute coryza, hypertrophic rhinitis, vasomotor rhinitis, hay fever, etc. It is said that the middle turbinates are most often involved in syphilitic hypertrophy. In the few cases I have seen this has not been my experience. My limited observation shows the more frequent involvement of the inferior turbinates. I have no doubt that ulceration, however, seems to be oftenest of the superficial variety and not to be easily differentiated from superficial ulceration of a non-specific type.

Ulceration, we must all agree, is commonly seen along with intranasal hypertrophic changes, and may readily occur as the result of pressure, or of nutritional errors, or from the atmospheric erosion due to narrowing of the passages. Indeed, while I freely admit I may be mistaken, I am not at all sure that the so-called superficial ulcer of intranasal secondary syphilis ever occurs in the absence of marked hypertrophy; hence, it would seem to be a question whether there really exists such a specific lesion, or whether the ulcer is not really due in all cases to mechanical or nutritional disturbances.

These, then, constitute my reasons for believing that the diagnosis of secondary intranasal syphilis is far from being a simple matter of inspection and subjective history. After all is said and done, the good old-fashioned therapeutic test may fairly be considered our safest guide in these cases. These lesions will not respond to any kind of topical treatment whatever, and they surely will respond to the administration of mercury. The prognosis appears to be uniformly good under appropriate treatment.

REPORT OF CASE

G. B., a man, aged 34, employed in an office, presented himself with symptoms indicating a severe chronic coryza, or vasomotor rhinitis. He had no pain, in fact, no other symptoms but the intolerable stuffiness of the completely blocked nasal passages and the annoyance of the copious mucous discharges. Inspection revealed only enormously hypertrophied inferior turbinates, yielding but slightly to cocain and epinephrin, and substantial adhesions between inferior turbinate and septum on the left side, while on the right side appeared four or five shallow ulcerated spots the size of a buckshot and covered with glairy mucus on the anterior aspect of the turbinate and on the septum. This condition had been present, he stated, for about three months. Previous to consulting me he had been treated by another rhinologist, who, besides using the usual astringents, had applied the galvanocautery to the ulcers, and had prescribed some systemic tonic mixture. No benefit had resulted after several weeks of this treatment. (This fact should have put me especially on my guard against syphilis.)

In a more or less casual way I considered the possibility of syphilis, looked the patient over for other evidences in the cursory manner of routine, and asked directly concerning a history of syphilis. The results were negative. The patient appeared above suspicion, and I proceeded on other theories. After a few days of unavailing treatment with local measures, I performed an inferior turbinectomy on the left side. The other structures, then becoming visible, appeared normal. Within a week or so a well-marked proliferating process commenced about the middle of the turbinate stump. On its continued growth I snared this off a few days later.

The patient then complained of his mouth and teeth feeling uncomfortable, though not painful. Examining the roof of the mouth, I found the arch of the hard palate about one-fourth filled with a smooth, hard, rounded oval mass, not at all sensitive, and presenting three or four superficial ulcers of apparently precisely the same character as those which appeared in the nose, and which had never shown the slightest improvement under local treatment up to this time. Still, I remained "asleep at the switch," and for a few days tried to reason out the pros and cons of a probable neoplasm, and was about to make a section for microscopic examination, when I awoke with a sudden and sickening thud. The rest of the story is briefly told. Mercury protoiodid and potassium iodid solved the problem that had baffled me for several weeks. The ulcers healed as if by magic; the thickened tissues resumed their normal condition; the distress of mind and body which had afflicted the patient disappeared, and he grew stout, well and happy. I had been dealing all the time with late secondary manifestations of syphilis, but I feel that I had at least some slight shadow of excuse for my tardy diagnosis.

Alas, that we cannot all comply with the gentle and epigrammatic admonition of the eminent Dr. Osler: "Know syphilis in all its manifestations, and what remains to be learned will not stretch the pia mater of a megalocephalic senior student."

INOCULATIONS OF NASAL SECRETION FROM PATIENTS WITH ACUTE POLIOMYELITIS *

I. STRAUSS, A.M., M.D.
NEW YORK

The assumption that acute poliomyelitis is a contagious disease is founded partly on experimental research. Flexner and Lewis were the first to call attention to the presence of the virus in the nasopharyngeal mucosa of monkeys ill with the disease, and that monkeys could be infected when the virus was applied to the scarified nasal mucosa. Leiner and von Wiesner found that successful inoculation resulted when the virus was smeared on the intact nasal mucous membrane. Recently Osgood and Lucas have reported the important fact that the virus can be present in the nasal mucosa of monkeys as late as five and one-half months after the acute stage of the illness. Landsteiner and Levaditi, in their last report, criticized the hypothesis of nasal contagion advanced by Flexner and Lewis, in that they had overlooked the determination of the presence of the virus in the nasopharyngeal mucus. They inoculated a macacus with the nasal secretion obtained from a monkey ill with poliomyelitis, but with negative result. They were also unsuccessful in inoculating a monkey with secretion which they had obtained from two men, one of whom had been ill some weeks, the other some months previously.

It occurred to me also that the virus ought to be present in the nasal mucus and, therefore, in August of last

---

* From the Department of Pathology, Cornell Medical College.

year I made inoculations which, though unsuccessful, have a certain value in solving this question of contagion. The material consisted of ten cases; seven occurred during the epidemic at Springfield, Mass.,[1] one in the small epidemic at Lake Placid in the Adirondacks, one in Manhattan, and the tenth in Brooklyn. The mucus was obtained by passing dry cotton swabs into the nasopharynx through the mouth. When removed they always had considerable mucus attached to them and in two instances they were a little blood-streaked, thus showing that they had come into intimate contact with the mucosa. After inoculation the swabs were placed into 10 c.c. of either normal saline solution or bouillon and kept either at room temperature in the dark or on ice. The solution was expressed from the swabs in order to remove as much of the virus as possible, and filtered through either Berkefeld or Chamberland filters. The virus is known to pass either of these filters. The filtrate was then centrifuged and either 2 or 4 c.c. were injected intracerebrally into rhesus monkeys.

TABLE OF INTRACEREBRAL INOCULATIONS OF RHESUS MONKEYS WITH NASOPHARYNGEAL SECRETIONS FROM PATIENTS WITH POLIOMYELITIS

Case.	Age, Years.	Onset of Disease.	Swab Taken.	Temp. When Swab Taken.	Clinical History.	Intracerebral Inoculation in Monkeys.
1	25......	8/6	8/13	....	Onset with T. 101 F. Severe headache, rigidity of neck. Aug. 7, facial palsy (nuclear) and palsy of right ext. rectus.	Swab 3 days in bouillon. Chamberland filter; 2 c.c. inoculated.
2	1¼....	8/7	8/11	During febrile stage.	Began with fever, vomiting and diarrhea. Aug. 10, T. 102 F.; unable to move arms or legs; stuporous; Aug. 11 had fever, but was brighter. Paralysis continued.	Swab kept 19 hours in bouillon. Berkefeld filter; 2 c.c. inoculated.
3	1¾....	8/8	8/13	3 days after fever.	T. 100.8 F. at onset. Aug. 9, T. 102 F. Aug. 10, facial paralysis. Aug. 11, normal temperature.	Swab kept 3 days in bouillon. Chamberland filter; 2 c.c. inoculated.
4	5......	8/8	8/13	2 days after fever.	Began with T. 102 F., rigidity of neck, paralysis of both arms. Aug. 10, T. 101.6 F. Aug. 13, T. normal; left leg paralyzed.	Swab 3 days in bouillon. Chamberland filter; 2 c.c. inoculated.
5	18......	8/8	8/13	102 F.	At first headache, retraction of head, rigidity of neck, painful joints, delirium. T. 102 F. Left leg paretic. Angina.	Swab 3 days in bouillon. Chamberland filter; 2 c.c. inoculated.
6	5......	8/11	8/13	No fever on day of paralysis.	Malaise for one week; fever Aug. 11. Paralysis of right leg Aug. 13.	Swab kept 3 days in bouillon. Chamberland filter; 2 c.c. inoculated.
7	62.....	8/31	9/4	After death.	Began Aug. 31. T. 101 F. Paralysis of both arms and legs developed Sept. 1. Died Sept. 4, of respiratory paralysis.	Swab kept in bouillon in ice-box for 5 days. Berkefeld filter; 5 c.c. inoculated.
8	1......	8/16	8/17	24 hours after fever.	Paralysis of deltoid.	Swab kept in bouillon 5 hours. Berkefeld filter; 2 c.c. inoculated.
9	15......	9/12	9/19	102.6 F.	Began with headache, pains in legs, fever. Sept. 13, legs paralyzed. Sept. 14, arms paralyzed; rigidity of neck; high fever. Sept 19, T. 102.6 F.	Swab kept in bouillon 2 hours. Berkefeld filter; 4 c.c. inoculated.
10	2......	9/18	9/28	24 hours after fever.	Onset with fever, vomiting; arm and leg paralyzed three days later. Then swallowing was difficult. Sept. 27, T. 102.4 F.	Swab kept in salt solution 4 hours. Berkefeld filter; 4 c.c. inoculated.

The virus did not have to be present in large quantities, since Leiner and van Wiesner had shown that a cord emulsion of 1 to 1,000 or 1 to 500 strength is more potent than stronger emulsions.

The accompanying table gives the data of the inoculations. No monkey became ill as a result of these inoculations. The experiments, therefore, seem to indicate the absence of the virus in the nasal mucus. This, of course, does not mean that it may not sometime be found in the human nasal mucosa as an excretion, just as is the case in the monkey, but if we are to regard the nasopharynx as the source of the contagion we ought to be able to demonstrate the presence of the virus in the nasal mucus.

One experiment was made to isolate the virus from the feces of a patient with an acute case. The feces of Patient 9 were mixed with salt solution on the same day that the nasal swab was taken. The mixture was filtered through a Berkefeld filter and the filtrate centrifuged. Four c.c. of the sedimented portion were injected intracerebrally into a monkey. The animal died of marasmus after four weeks. The autopsy revealed no cause of death. An emulsion of his brain and cord was inoculated into a second monkey with negative result. This experiment, so far as we are aware, is the only one in which an attempt has been made to demonstrate the virus in the human feces.

---

[1] I wish to express my thanks to State Inspector Boyd and Drs. Emerson, Tracy, Hirsch and Rearden of Springfield for their kind assistance.

THE ETIOLOGY OF VERRUCA

DOUGLASS W. MONTGOMERY, M.D.
Professor of Diseases of Skin, University of California
SAN FRANCISCO

It may be assumed as true that a simple traumatism can give rise to a wart, but in order to do so the injured tissues must themselves be in a favorable condition to react in this pecular way to the traumatism. The injury, therefore, would be the provocative cause of the verruca, and the condition of the tissues the predisposing cause. Verruca or papilloma is primarily an epithelial growth, and only secondarily is the subjacent connective tissue affected. Moist heat, inducing maceration of the epithelial cells, is one of the most important of predisposing causes of the neoplasm, and acts probably by exciting epithelial cells to grow more luxuriantly, and particularly so when a traumatism draws an increased supply of blood to the part. The frequency of papilloma of the sole in the flat-footed is an example of this.

My attention was first drawn to this by Dr. W. A. Hardaway of St. Louis. These patients almost always suffer from hyperidrosis of the feet, and the consequent maceration of the epithelium of the sole constitutes the predisposing tendency to the formation of papilloma in this region. Nature seldom afflicts us with one thing at a time; she diversifies our torments. The arch of the foot breaks down, we get hyperidrosis, and then that most painful affliction, papilloma of the sole, appears. In this way we finally become intimately acquainted with grief.

But maceration of the epithelial cells, predisposing them to this peculiar form of neoplasm may, I am convinced, be caused by hot water alone, of which the following is an instance:

About July 4, 1905, a man came to me with a painful swelling under the ball of the right foot, which was quickly seen to be a verruca. There was the usual circumscribed callus with the bunch of dots in the center representing the upgrowing connective tissue filaments. A strong salicylic acid ointment was ordered to be applied to the sole each morning, so that in walking he would tramp it well in during the day. When the wart was laid bare of its surrounding mass of epithelial cells, it was burnt with silver nitrate, but others came, and in great numbers.

In casting about for the reason of this persistence of the affection, I told the patient of Dr. Hardaway's observation in regard to the association of flat-foot and papilloma of the sole, and explained that probably flat-foot was only an incident in the etiology, and that the essential feature in all likelihood was the hyperidrosis. He shortly afterward related to me a most interesting story. In the hotel where he boarded there was an abundance of hot water, and every night he used to soak his feet in this for no other reason than that the heat gave him pleasure. One evening on returning to his rooms he found he had mislaid his key, and the servant with the pass-key was not in sight. The patient, being athletic, entered through the transom and jumped to the floor. He lit on the ball of his right foot, and remembered that it stung quite severely. Shortly afterward his trouble appeared and on the site of this very traumatism.

A few days after this explanation, the great fire occurred, and threw the patient and his physician both out on the street. He had some fire insurance in one of the companies that tried to evade or shave all its policies; the city had no street-car service or other means of public conveyance, and all the work of getting proof of loss properly presented had to be done on foot. In addition to this he had to hunt for me. In this interesting interval the papilloma of the sole did not neglect to torment him. After he had found me I had my troubles, for I wished to curette the wart, and as all the surgical instrument stocks had been destroyed in the catastrophe, it was difficult to find a suitable tool. Finally by thorough curetting under cocain and cauterization with nitrate of silver, the papillomas were eradicated with no subsequent return.

The hot-water bathing, I have no doubt, had much to do with the occurrence of warts in this case.

An active proliferation of the epithelial cells favors the occurrence of verrucæ, and this is probably why they so frequently occur in youth, when all the cells of the body are in very active growth. In seborrhea also the epithelial cells, both of the skin and of the mucous membranes, proliferate with unusual activity, and both verrucæ and paillomas are apt to appear. Verrucæ of the scalp, for example, are frequently associated with seborrhea of the scalp.

In seborrhea, moreover, there is not alone a more active proliferation of cells from the very fact of the existence of seborrhea, but those having seborrhea sweat more easily and profusely, so that they have a double predisposition toward papilloma or verruca.

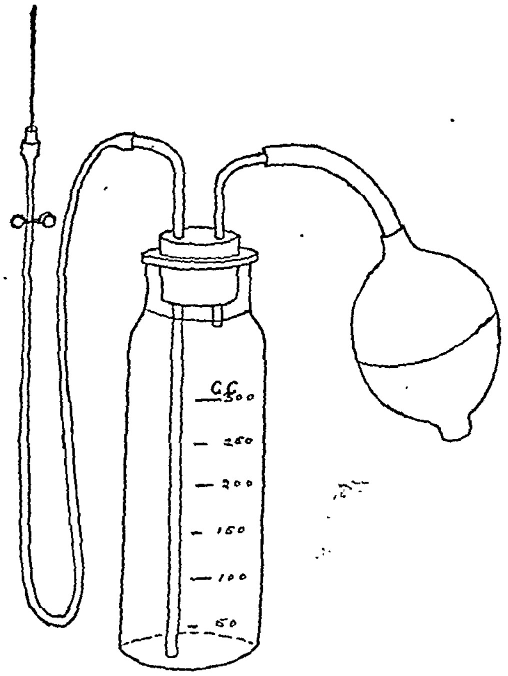
A traumatism alone, however, I am convinced may give rise to these troublesome growths, and it is not strange that it should [illegible] so, for if injury causes a continuously increased supply of nourishment to a part it may cause increased cell proliferation through over-nourishment, and hence may predispose to papilloma.

323 Geary Street.

A SIMPLE APPARATUS FOR THE INTRAVENOUS INJECTION OF SALVARSAN OR OTHER DRUGS

WILLIAM F. BERNART, M.D.
CHICAGO

The nearly universal recommendation of the intravenous use of salvarsan has brought up the question of which is the most convenient and best contrivance for the administration of this drug. A large glass syringe is probably the simplest appliance for giving the injection; however, it is not always possible to get a syringe which will hold 300 c.c. If it is administered by gravity, it is essential for the operator to have an assistant. The apparatus which I am going to describe can be constructed at a small cost, answers the purpose in every respect and can easily be operated by the physician alone. The materials required are:



Apparatus for intravenous injections by means of a pressure-bottle.

Wide-mouth bottle, capacity 360 c.c. (12 oz.).
Rubber stopper to fit the bottle, two perforations in stopper.
Two glass tubes to fit perforations, one sufficiently long to reach to the bottom of the bottle, the other to reach through the stopper.
A double-valved atomizer bulb.
Twelve to eighteen inches of India rubber tubing to fit glass tubing.
Hypodermic needle, platinum.
Clamp for tubing.
Glass funnel and filter-paper.
Glass-stoppered bottle (360 c.c.) and 50 to 100 glass beads.

The salvarsan is dissolved and mixed in the glass-stoppered bottle according to directions accompanying each package of the drug. After the solution is properly prepared it is filtered into the reservoir of the apparatus. While waiting for the solution to filter, the reservoir is placed in a bowl of hot water so that by the time the filtration is completed the solution is of a proper temperature for immediate use. If desired, the salvarsan can be prepared in the reservoir of the apparatus and if a fine piece of muslin is tied over the lower end of the long tube, the solution can be filtered simultaneously with the injection. After the reservoir is filled, the rubber stopper, with the glass tubes inserted, is tied tightly into place. The needle and hose are elevated, the bulb is pressed and all air is expelled. As soon as the liquid spurts through the needle in a solid stream the hose is clamped and the needle is inserted into the vein of the patient. When it is certain that the needle is in the proper position the clamp is loosened and by pressure on the bulb the fluid is readily forced into the circulation.

According to the air-pressure used, the 300 c.c. of solution can be injected in from four minutes to as long a time as may be deemed advisable. When the solution is all utilized the air slowly follows the fluid up the long glass tube, giving the operator plenty of time to close the clamp before any air can enter the veins. The needle is then withdrawn and the puncture wound sterilized and closed with the tincture of iodin.

The compactness of this apparatus permits of but little loss of heat by radiation and the giving of an injection is under the full control of one individual.

42 Madison Street.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES."

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

PRE-DIGESTED LIQUID FOOD. Mulford.—Pre-digested Liquid Food, Mulford, contains 10 per cent. of protein and 10.5 per cent. of carbohydrates (dextrose, lactose and sucrose) in a vehicle containing glycerin about 1½ per cent., saccharin about .01 per cent. (1/20 grain in a fluidounce) and about 30 per cent. of native wines, fortified with alcohol sufficient to bring the alcohol content up to 16 per cent. absolute alcohol per volume.

Pre-Digested Liquid Food, Mulford, is prepared by digesting fresh lean beef with hydrochloric acid and pepsin and digesting milk casein first with hydrochloric acid and pepsin and after neutralization with pancreatin. The solutions after digestion are concentrated in vacuo and mixed with the other ingredients.

It is a light yellowish-red liquid, having an aromatic odor and not unpleasant taste. Its specific gravity is about 1.07. When evaporated to constant weight it leaves about 25 per cent. of residue.

Actions and Uses.—See Medicinal Foods.

The nutritive value of 500 Gm. corresponds to 416.3 calories, of which 201 are due to protein and 215.3 to carbohydrates. The same quantity of milk represents 360 calories, of which 84 are due to protein, 98.4 to carbohydrates and the rest to fats.

Manufactured by H. K. Mulford Co., Philadelphia. (Not patented or trademarked.)

ANTIRABIC VACCINE

The American Biologic Company, Kansas City, Mo.

Pasteur Antirabic Vaccine.—The virus is prepared according to the method of the Hygienic Laboratory, Washington, D. C. An amount of the dried cord, sufficient for one dose, is suspended in a mixture of 66⅔ per cent. glycerin and 33⅓ per cent. of physiologic salt solution, and sent daily by mail, accompanied by a syringe containing sterile physiologic salt solution for further dilution at the time of administration. The treatment requires 18 to 21 days.

ARTICLES ACCEPTED FOR N. N. R. APPENDIX

Borcherdt Malt Extract Co., Chicago.

Borcherdt's Malt Extract Plain.—A preparation essentially equivalent to Extractum Malti U. S. P. and containing 10 per cent. of glycerin. U. S. Trademark Nos. 64,467, 64,481.

Borcherdt's Malt Olive with Hypophosphites.—Each 100 c.c. is said to contain Borcherdt's Malt Extract 70 c.c., California olive oil 20 c.c., C. P. glycerin 10 c.c., calcium hypophosphite 0.64 gm. (3 grains in a fluidounce), sodium hypophosphite 0.64 gm. (3 grains in a fluidounce). U. S. Trademark Nos. 60,422, 64,467.

Borcherdt's Malt Soup Extract.—Borcherdt's Malt Soup Extract is a mixture obtained by adding potassium carbonate 1.1 gm. to each 100 gm. of Borcherdt's Malt Extract, diluted with one-half its volume of distilled water, and evaporating in vacuo to a specific gravity of 141. U. S. Trademark No. 64,467.

Therapeutics

PREVENTION OF PULMONARY TUBERCULOSIS

POINTS WHICH MUST NOT BE FORGOTTEN

The announcement by Dr. Robert Koch, in 1882, of his discovery of the tubercle bacillus and its relation to tuberculosis opened a new era in the study and management of that disease. He proved conclusively that the tubercle bacillus is the cause of tuberculosis, and opened the way to the modern treatment of the disease. Tuberculosis does not occur in the absence of the tubercle bacillus, and the recognition of this fact has greatly simplified the problem with which the medical profession had been struggling almost hopelessly for centuries.

It is now generally recognized that the most common method of transmission of this terrible disease from one individual to another is by the transference of the tubercle bacillus from the sick person to his neighbor by means of the secretions or exudations from the lungs, and from the upper respiratory organs where the tubercle bacillus may be lodged on the mucous membranes and in the mucus and other secretions of those membranes. This makes manifest the great importance of a suitable disposal of the matter expelled from the nose and mouth. It has been found that not only do the masses of sputum of considerable size which are expelled from the lungs contain tubercle bacilli, but also that the smaller particles of moisture and mucus which are expelled in such small quantities as to be almost unrecognizable, in many instances also contain the dreaded bacillus. These small particles, or droplets as they are commonly called, are expelled usually with the so-called "dry cough" which is not accompanied by the expulsion of the larger masses of sputum. The problem, then, is to receive and take care of the matter expelled from the mouth and nose of the tuberculous patient, whether this comes from the lungs, throat, nose or mouth.

Various devices have been provided for collecting and destroying the larger masses of sputum. In the room where the sick person spends most of his time, a metallic cuspidor with an easily opened cover is very useful. This cuspidor should contain water, preferably rendered antiseptic by the additon of a 5 per cent. solution of phenol (carbolic acid). This cuspidor should be large enough for the patient to deposit the sputum in it easily. Other forms of receptacle include a tin cup in which is placed a pasteboard box into which the patient expectorates. For patients who are walking about, a small cup with a removable cover is convenient. This should be made so that even when it is tipped over the sputum will not escape. When it is impracticable to use any of these special receptacles, the sputum may be received on pieces of cloth or on paper napkins. It is necessary that the patient should be provided with a receptacle for these things which is impervious to moisture and which will not allow the sputum to penetrate to the exterior of it, and which may be thoroughly cleansed and disinfected when the pieces of cloth or paper are removed from it. The use of gauze is recommended by many writers, but is less desirable than paper or pieces of cloth, because of the danger that the sputum will penetrate the meshes and extend the infection. Whatever the substance used, it may be deposited in a convenient stiff paper bag, and the bag, later, with its contents, burned. The water and sputum in the cuspidors, after disinfection, should be thrown into the water closet.

All papers and cloths on which sputum has been deposited should be burned. In many homes, under the modern conditions of heating and cooking with gas stoves, difficulty may sometimes be found in accomplishing this, but the importance of destroying paper or cloth contaminated with tubercle bacilli is so great that the difficulty should not be regarded as an adequate excuse for failure to effect perfect destruction by incineration.

Even outside of the house or on the street, the same care should be exercised in collecting and destroying the sputum. Boards of health and municipalities have exercised themselves to prevent the spread of the disease in this way to the extent of passing ordinances forbidding spitting on the sidewalk. Such ordinances are not enforced so thoroughly as they should be, but for the tuberculous patient spitting in the gutter is objectionable, and should not be encouraged. In fact, if all spitting, except into some suitable receptacle or some substance which could be destroyed, were forbidden, the condition of the world, and especially of the larger cities, would be greatly improved. Certainly, everyone should be taught, even from childhood, that spitting is inelegant, and that no one should cough, either in public or private, without holding before his mouth some paper or cloth so as to receive on it any matter which may be expelled, even involuntarily, from the mouth or nose.

In the same way, the discharges from the nose of the tuberculous patient should be received on paper or cloth which can be destroyed. If occasionally the ordinary handkerchief is used to receive the discharges from the mouth or nose, this should be placed in water before the discharge is allowed to dry, and should be boiled before being placed with the other soiled clothing for the usual family laundry.

It is impossible to emphasize too strongly the necessity of the most minute care to prevent the dissemination of the discharges from the lungs, nose, throat and mouth of the tuberculous patient. When, either from accident or carelessness, these discharges are not properly cared for, but are allowed to fall on the floor or street, as they become dry, the tubercle bacilli are, so to speak, set free in the dust, and are liable to become a source of danger to healthy people. This suggests the importance of using every possible measure to prevent the dissemination of dust in apartments or on streets where many people are accustomed to go. The feather duster, so dear to the average housewife for removing dust from furniture and bricabrac, should never be allowed inside the residence of a civilized citizen. Ordinary sweeping with a broom should not be allowed unless special precaution has been taken to prevent the raising of dust. It has been recommended for this purpose that a newspaper be dampened, torn into pieces, and thrown upon the carpet before the broom is used. Where there is no carpet on the floor, moist sawdust is useful to prevent the raising of dust. Far better than the broom for the remov of dust and dirt from rooms is the vacuum cleaner. It is greatly to be hoped that it will not be long before the broom will be a forgotten implement of cleansing and superseded entirely by the vacuum cleaner.

In the streets of cities the dust which is raised by the wind or by vehicles is frequently germ laden, not only with the bacilli of tuberculosis, but with other disease germs, especially those of influenza and pneumonia. Hence the importance of street cleaning and of street watering, the former diminishing the amount of dust liable to be raised by the wind or vehicles, and the latter preventing whatever there may be from being blown about.

These are the most important considerations to be borne in mind in preventing the transmission of the disease from the patient to those who come into the neighborhood or the region where he is or has been. There is another point of view to be taken into consideration, and that is increasing the resistance of feeble people against the attack of the tubercle bacillus. It would be impossible, perhaps, to prove that no child has ever been born infected with tuberculosis from its parents before birth. In fact, it is generally conceded by authorities on the subject that such antenatal infection is possible, but practically it certainly is very rare. That tuberculosis is hereditary in the sense in which that statement would have been understood previous to thirty years ago is recognized now as being impossible. On the other hand, that many children born of parents, one or the other of whom has suffered from or has died of tuberculosis, are more likely than the children of healthy parents to suffer from tuberculosis is recognized by everyone. But the interpretation of this observation which now prevails is that the child does not inherit the disease, tuberculosis, but that he inherits a predisposition to that disease, that he inherits a weakness of physique which renders him more liable to be attacked by the disease than others who do not inherit such weakness. One of the most important problems to-day in regard to the prevention of pulmonary tuberculosis is to raise the vitality and resisting power of these individuals so that they will not easily become affected by the tubercle bacillus. For at present it is recognized that this bacillus is so generally disseminated throughout the places occupied by the human family, that many people become the hosts of the bacillus without knowing it, and if their resistance is sufficiently strong, do not suffer any ill effects from it, but cast it off.

It is now well understood that the diet of patients with a tuberculous tendency must be nutritious, but it is frequently necessary to express a caution against the use of alcoholic drinks. Many people believe that these beverages are a valuable tonic, increasing the appetite and improving the digestion and general nutrition, and therefore believe that they are useful for people who seem to have a predisposition to tuberculosis. As a general rule, it may be stated that this belief is a mistaken one, and that in the absence of any special indication for their use most individuals, even if they are not robust, are better off without the habitual use of alcoholic stimulants.

In order to raise the resisting power of children with tuberculous parents, so that they may not readily contract the disease, many things must be taken into account. Perhaps the most important of all is the question of pure, fresh air. This at once brings up the question of residence. Families, any member of which is recognized as being weak or having under-average resisting power, should consider carefully the selection of a place of residence. They should not select a tenement house in a crowded city, but should, if possible, secure a residence in the country suitable for a single family and surrounded by air on all sides, and in which every room has a direct supply of fresh air and sunshine. The house should be built preferably on elevated ground, and on gravel or sandy soil. Low ground or clay ground should be avoided. Of course the residence should be selected not only with reference to fresh, pure air, but with reference to the facility of reaching the work in which the members of the family are occupied. This entails transportation facilities, which are of great importance. But not all people can live in the country where they can occupy separate houses. If a family embracing feeble members is obliged to live in the city, a residence should be found in the less thickly populated part of the town. These people should avoid tenements which have dark rooms, rooms in which there are no windows toward the outside of the house through which fresh air and sunshine may be admitted. In recognition of this fact, when cities are laid out the streets should be made broad, and the height of the houses should be limited in order that through narrowness of the streets and height of the adjacent buildings the air and sunshine may not be practically prohibited from the dwellers.

The manner of living within the house is also important. Rooms which have not windows opening directly out-of-doors should not be used for bedrooms. It is preferable that no bedroom should be occupied by more than two persons, and it is very desirable that each individual should have a separate bed. The windows should be kept open at night so that the occupants may constantly have fresh air to breathe. Infants require fresh air quite as much as adults, but they are less able to stand inclement weather or cold air than older children, and they should be gradually accustomed to the breathing of, and exposure to, cold air. It is of course necessary, in the matter of fresh air and cold air, to use common sense, as in all other matters pertaining to the health of individuals. The window through which fresh air is admitted should not necessarily be opened equally widely at all times; or if it is, varying degrees of protection against the incoming air may need to be employed at different times. For instance, if a strong, cold wind is blowing in the window at the hour of retiring, the window should either be partly closed, or a screen or curtain or blind should be placed in front of it to break the draught; otherwise, the sleeper will be very apt to awaken in the morning with a coryza.

Delicate children should not be sent to school too young, or confined in the schoolroom for many consecutive hours. They should be encouraged to remain out-of-doors, and to engage in active, but not too violent play. They should have longer hours of sleep than strong, robust children. For children from five to ten years of age, ten hours of sleep are none too many.

Breathing exercises should early be taught to all children, and especially to weak children, so as to increase the breathing power and promote the development and expansion of the chest.

Another consideration of great importance is the matter of food. Weak children should be fed regularly. Their food should be varied, nutritious, and easily digestible. Milk should be an important article of diet for every feeble child. Eggs are also useful, but should not be offered so frequently that the child will acquire a distaste for them. While sugar is a necessary ingredient of the diet of every growing person, yet it should not be provided for children in excess, especially in the form of pie, cake and candy. Children should be taught to eat fruit and vegetables, and a limited amount of meat. It is exceedingly important that they should be brought up and taught to eat fatty substances, such as butter, cream, and the fat of meat. This will do much to promote their nutrition and to increase their resisting power against disease.

With reference to providing abundance of fresh air for growing children as an aid in the prophylaxis of pulmonary tuberculosis, it is always necessary to examine the upper respiratory passages of the child in order to determine whether there is ready access of air to the lungs. Often it will be found that a deviated nasal septum, hypertrophied turbinates, nasal polypi, or adenoids in the vault of the pharynx interfere seriously with nasal respiration. Also, hypertrophied tonsils interfere with the taking in of an adequate supply of air. These conditions should all be looked for, and, when found, should be remedied by appropriate medicinal or operative treatment.

With reference further to the obtaining of an adequate supply of fresh air, the dress of the patient, especially if a girl or woman, should be carefully considered. High collars, or very tight collars about the neck interfere decidedly with respiration, and should be forbidden. The wearing of corsets too tightly laced about the waist interferes with abdominal respiration, and frequently produces displacement of the abdominal viscera and deformity of the bones of the thorax.

While the clothing should be sufficiently warm to protect the skin from changes in temperature and from draughts, it should at the same time be loose enough to form no obstacle to free respiration.

INTESTINAL WORMS—A CORRECTION

In The Journal, March 18, 1911, page 813, under the discussion of *Ascaris lumbricoides*, the statement was made that this worm lives in the intestines of cattle and pigs, and may reach man by their excrement contaminating water and vegetables. The statement was incorrect. The ascaris of the pig is different from that infecting man, and cattle do not seem to have this disease; hence the contamination of water and vegetables with the eggs of the *Ascaris lumbricoides* that infects man comes from infected human excrement used as a fertilizer, or by the direct contamination of water.

Massage of the Prostate.—Before one undertakes to massage the prostate, he must bear in mind the object sought, *viz.*, to improve the circulation and thereby aid absorption of the infiltrate, and secondly, to express any macroscopic pus (abscess). It is more important to bear the first indication in mind and execute the massage gently, than to do it too vigorously. The procedure should cause little or no pain to the patient, should be kept up for about five minutes, and should not be repeated oftener than twice a week, but the main reliance should not be put on massage alone. The periprostatic tissues should be gently massaged as well. The prostate can be made more accessible by making counterpressure over the symphysis pubis with the disengaged hand. The prostatic circulation can be more powerfully influenced by the prostatic vibrator, which is even less painful than the finger massage. When there exists a great deal of interstitial prostatitis, as evidenced by a nodular prostate, the massages do not influence the prostate, as we cannot hope for any absorption of organized connective tissue.—G. Greenberg, in *American Journal of Urology*.

SATURDAY, APRIL 22, 1911

STANDARDIZATION OF DIGITALIS

One of the greatest handicaps to exact drug therapeutics is the fact that "impressions" either of the physician or of the patient play such an important part. Many other branches of medicine have been put on a truly scientific basis as a result of careful quantitative work, in either the laboratory or the clinic, or in both, but in drug therapeutics, such expressions as "the drug seemed to do good," are constantly used without the slightest attempt to measure any tangible effect, or to compare the case under treatment with one running a natural course. It is this habit of reliance on impressions which led physicians, fully as wise as any now living, to use for centuries drugs now entirely discarded; and it is this habit which keeps the modern pharmacopeias overburdened with equally useless drugs. It is rather surprising, however, to see what an important part "impressions" play even in the choice of a drug and the method of its preparation, for these would seem to be amenable to exact laboratory control. That such is the case however, is strikingly illustrated in a recent publication of Hale[1] on digitalis.

Hale has endeavored to trace the origin of a number of commonly accepted views concerning this invaluable drug and to test them experimentally in the laboratory. Some of his conclusions may be summarized as follows: The view that the leaves of the second year's growth are more potent than those of the first year—a view adopted by most pharmacopeias and by the Brussels conference—seems to be founded on tradition only. The only experimental work done had shown that the first-year leaves were fully as active as those of the second year; Hale, experimenting with four lots of first-year leaves, found them to be from 28 to 40 per cent. more active than the best second-year leaves obtainable. The view; or rather impression, that the leaves of wild-growing plants are more potent than those of cultivated plants—a view which finds expression in the French, German and some other pharmacopeias—is also shown not to rest on a scientific basis. Hale admits that some wild-growing leaves are more potent than some garden-grown leaves, but believes that cultivation *per se* has nothing to do with it, and points out that Allen's English leaves, which give high assay values, are garden-grown. He also discusses the influence of moisture and of heat on the keeping quality of leaves; he found that an amount of moisture sufficient to permit molding might cause a loss of potency of 90 per cent. in a few months, but found no justification for the statements sometimes made in the interests of special preparations that leaves dried in a vacuum, or preparations made by macerating leaves with cold water, have special advantages. Although these experiments should extend over a number of years before a final decision is reached, as far as they go they indicate plainly that physicians and pharmacists for decades have been groping in the dark after the causes of the well-known variation in the potency of digitalis leaves, and have often attributed it to irrelevant circumstances. The real cause is unknown, but seems to be connected with the nature of the soil, the character of the season, etc.; it is only by the use of physiologic standardization that uniformly active leaves can be obtained at present.

Of the galenical preparations of digitalis, Hale never found the fluidextracts to assay, relatively, as strong as the tinctures; this indicated incomplete extraction. The practice (one much encouraged by certain drug houses) of preparing pseudotinctures by diluting the fluidextracts is condemned; such "tinctures" have as a rule but from one-half to two-thirds the strength of genuine tinctures. It was found that whereas weak alcohol (35 per cent.) was as efficient as stronger alcohol in extracting the leaves, preparations made with the stronger alcohol had the advantages of containing less inert matter and of retaining their potency much better. A number of official extracts showed little deterioration (from 4 to 8 per cent.) in twenty-two months, whereas a number of proprietary preparations containing a smaller percentage of alcohol had deteriorated to a much greater degree (even to 33.3 per cent.) in the same period. Hale suggests that the makers of special preparations should submit them to much more rigorous tests than is done at present, and that physicians should use them as seldom as possible unless assured, by a system of dating, of their very recent preparation. The importance of this precaution was shown by the fact that one sample of a widely used proprietary preparation, secured from a reliable pharmacy, had lost practically all digitalis action and had become a cardiac depressant. Hale believes that the manufacture of special digitalis preparations should not be encouraged.

The second part of the bulletin deals with special digitalis preparations, such as tablet triturates, hypodermic tablets, fluid glycerates, etc. Tablet triturates obtained from different manufacturers were found to vary in strength by as much as 360 per cent., about the degree of variation found in official tinctures and fluidextracts. Hypodermic tablets of digitalin were also found to vary by as much as 230 per cent. The fluid glycerate was found to have but about 40 per cent. of the strength of the official fluidextract.

[1] Bull. 74, Hyg. Lab. P. H. and M.-H. S., Washington, D. C.

The bulletin closes with a discussion of two widely advertised proprietary preparations, digalen and digipuratum, embodying conclusions previously published.[2]

A perusal of this bulletin will place the practitioner in a much better position to form a judgment of the character of the digitalis preparation he uses. The work which it embodies should be of value in improving the pharmacopeial requirements of this important drug.

TWO SURGICAL PATRIARCHS

Detailed sketches of the lives of two men who were prominent in the surgery of the latter half of the nineteenth century in America have recently appeared; and teachers of medicine, as well as those who are interested in medical history, will find them storehouses of valuable material.
